# ABSTRACTS

The Gerontological Society of America
63rd Annual Scientific Meeting
November 19–23, 2010
New Orleans, LA

Abstracts are arranged numerically by session and in the order of presentation within each session.

## SESSION 5 (PAPER)

## CAREGIVER HEALTH AND BURDEN

### CAREGIVING AND CLINICALLY-ASSESSED BIOLOGICAL RISK FACTORS: EVIDENCE FROM MIDUS II

S. Kang[1,2], N. Marks[1,2], *1. University of Wisconsin-Madison, Madison, Wisconsin, 2. UW Institute on Aging, Madison, Wisconsin*

Guided by a life course perspective and biopsychosocial approach to health, this study aimed to add to a population perspective on caregiving and health-related biological risks of family caregiving by (1) examining how providing caregiving for a child, spouse, parent, or parent-in-law due to their illness or disability (in contrast to not providing caregiving for any kin or nonkin) is linked to allostatic load (a 15-item composite measure of biological risk) and three subscales of allostatic load (metabolic dysfunction, inflammatory dysfunction, hypothalamic-pituitary-adrenal axis/sympathetic nervous system [HPA/SNS] dysfunction) among midlife and older adults, and (2) evaluating how gender might moderate the link between caregiving and health-related biological risks. Data from a subsample of MIDUS II (Midlife in the U. S., 2005) respondents ages 34 to 83 that were recruited for additional clinical and biological assessment (N = 1054) were used to estimate multivariate models that also adjusted for numerous sociodemographic factors. Results revealed that providing caregiving for a spouse was associated with a greater risk in metabolic dysfunction. Models evaluating moderation of caregiving risks to biological health by gender revealed that women who were providing caregiving for a parent-in-law reported higher levels of allostatic load and its subscale indicators of inflammatory dysfunction than their men peers. Overall, results suggest that caring for a spouse is linked to important biological health risk for women and men, and caring for a parent-in-law is linked to important biological health risk for women.

### CAREGIVING TO ADVANCED CHRONIC ILLNESS (CHF/COPD) PATIENTS

A. Wilkinson[1], S. Berry[2], *1. School of Nursing, Midwifery and Postgraduate Medicine, Edith Cowan University, Joondalup, Western Australia, Australia, 2. Rand Corporation, Santa Monica, California*

Background. The cost and responsibility for much of the care of seriously ill, elderly persons living in the community with advanced, eventually fatal, chronic illness has been shifted onto family members. Chronic organ system failure presents a distinct illness trajectory with an erratic and unpredictable course characterized by episodes of acute illness and periods of relative stability set against a background of gradual, progressive disability. Current caregiving research has not yet described the challenges, stresses, and rewards that accompany caregiving for individuals with advanced chronic organ system failure. This project sought to describe the factors that influence caregiver outcomes in caregiving to advanced CHF and COPD patients. Methods: We conducted a series of 9 focus groups (8-10 adults each), 18 years or older, who were currently providing care for a patient with advanced chronic CHF or COPD. Focus group discussion topics were identified from the literature Initial analysis resulted in a classification system for major topics derived from the material and a second analysis by both researchers determined a final set of themes. 65Results: Five major themes were identified: (1) how caregivers describe their experience, (2) prognosis/uncertainty impacts, (3) objective burden (tasks), (4) role conflict/reversal, and (5) subjective burden. Findings from this exploratory work suggest that interventions should provide information about topics of specific relevance to CHF/COPD caregivers (e.g., disease processes, prognosis, what to expect, symptom and self-management, and should address caregiver/patient social isolation. Details and implications for future research and intervention policy will be discussed.

### BEHAVIORAL PROBLEM SUBTYPES IN DEMENTIA AND EFFECTS ON INFORMAL CAREGIVER HEALTH, HEALTH BEHAVIORS, AND SERVICE USE

J.M. Thorpe[1], C. Thorpe[2], *1. School of Pharmacy, University of Wisconsin - Madison, Madison, Wisconsin, 2. School of Medicine & Public Health, University of Wisconsin - Madison, Madison, Wisconsin*

METHODS: Data were drawn from the Resources for Enhancing Alzheimer's Caregiver's Health, a sample of 1,222 family caregivers. Latent class analysis (LCA) was applied to the Revised Memory and Behavior Problems Checklist to identify patient subtypes with similar behavioral symptoms. We used multivariate regression to assess associations between behavioral problem subtype and caregiver depressive symptoms, unhealthy behaviors, health service use, and use of in-home services for the dementia patient. RESULTS: LCA revealed four behavioral-problem subtypes: "minimally symptomatic" (23.4% of patients; reference group in multivariate analyses); "memory problems only" (32.1%); "depression problems only" (23.0%); problems with memory, depression, and disruptive behavior, "severely symptomatic" (21.5%). In multivariate analyses, caregivers of patients in all three behavioral problem subtypes had significantly greater depressive symptoms and more doctor visits, and were more likely to visit the emergency room or a mental health provider and use antidepressants. Caregivers of patients with "memory problems only" and "severely-symptomatic" patients were 1.5 times more likely to have gained 10+ pounds; the latter group was also 1.9 times more likely to eat < 2 meals per day. Caregivers of patients in the "severely-symptomatic" group were less likely obtain in-home nursing or home health aid. CONCLUSION: All subtypes of behavioral problems in dementia patients negatively affected caregiver health, but caregivers facing the most varied and severe behavior problems were particularly vulnerable and were less likely to use in-home supportive services. Results suggest that increased attention to behavioral problems in dementia patients could reduce negative health effects, unhealthy caregiver behaviors, and healthcare resource use in the caregiver.

### A DIMENSIONAL ANALYSIS OF CAREGIVER BURDEN AMONG SPOUSES AND ADULT-CHILDREN

M.Y. Savundranayagam[1], R. Montgomery[1], K. Kosloski[2], *1. Helen Bader School of Social Welfare, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, 2. University of Nebraska - Omaha, Omaha, Nebraska*

Caregiver burden is a multidimensional construct that addresses tension and anxiety (stress burden), changes in dyadic relationships (relationship burden), and time infringements (objective burden) resulting from caregiving. The goals of this study were to (a) assess whether the dimensions of burden were the same for caregiving spouses and adult-children, (b) examine the role of assisting with problem behaviors and activities of daily living as predictors of different dimensions of burden, (c) investigate the role of each type of burden on outcomes such as caregiver health and intention to institutionalize the care receiver, and d) assess whether the relationships between predictors and outcomes of the different dimensions of caregiver burden differ the for the two groups of caregivers. This study included 280 spouse/partner and 243 adult-child caregivers of persons with chronic illnesses. Analysis using two-group structural equation modeling showed that the factor structure of burden was the same for spouses and adult-children. For both groups, assisting with caregiving tasks was directly related with objective burden, whereas problem behaviors were directly related to all three types of burden. Stress burden was the only predictor of caregiver health for both groups. Group differences were observed for factors that were linked with intent to place. Relationship burden and problem behavior were significant predictors of intent to place among children, whereas stress was a significant predictor among spouses. Objective burden was not a significant predictor of caregiver health or intent to place for both groups. Implications regarding the differing needs of spouses and adult-children are discussed.

### SALUTOGENIC MODEL OF HEALTH EXPLAINS 24-HR BP IN AFRICAN AMERICAN CAREGIVERS AND NONCAREGIVERS

S. Picot[1], J.A. Zauszniewski[2], M. Wykle[3,1], S.M. Debanne[4,1], *1. School of Nursing, University of Maryland, Baltimore, Maryland, 2. Case University, Cleveland, Ohio, 3. Case University, Cleveland, Ohio, 4. Case University, Cleveland, Ohio*

Background. People strive to attain, maintain, and regain resources to combat stress and remain healthy. The salutogenic model of health proposes a link between six generalized resistance resources (GRRs) and stress reduction indicators [e.g., blood pressure (BP)]. Objective. Individual and combined effects of six GRRs on BPs were tested in a random sample of African American (AA) caregivers (CGs) and noncaregivers (NCGs). Sample. 202 CGs and 205 NCGs with Age (M = 56/55) CGs/NCGs, Majority (79%) had > HS diploma; Income (Mdn = 15,000-19,999/ $20,000 - 29,999) CGs/NCGs; Married 48%(n = 97)/ 58% (n = 119), CGs/NCGs. CGs and NCGs differed on income (X2 = 24.28, p <.01) and married (X2 = 4.11, p <.05). Measures: Resources: age, lack of exercise, alcohol intake; Hollingshead's SES, Daily Hassles Scale, learned resourcefulness- Self-Control Schedule; Inventory of Socially Supportive Behavior Revised, and use of prayer and was 24-hour mean systolic BP. Procedure: face-to-face interviews and ambulatory BP monitors. Analyses: 24-hr SBP was regressed on the six resources at once for CGs/NCGs separately. Results:CGs, F(8,191) = 7.30, p <.001 and R2 =23.4%; NCGs, F(8,195) = 8.70, p <.001 and 26.3%. Specifically, CGs: age (b = 0.40, p < .001), learned resourcefulness (b = -0.18, p < .01), daily hassles (b = 0.14, p < .05), exercise (b = -0.16, p < .05), and quality of social support (b = 0.12, p < .08); NGGs: age (b = 0.45, p < .001), use of prayer (b = -0.18, p < .01), and alcohol intake (b = 0.23, p < .001). Implications: Except for SES, the salutogenic model can serve as a basis for theory guided interventions to reduce stress among AA CGs/NCGs.

# SESSION 10 (PAPER)

## LONELINESS

### SOCIAL SUPPORT DECREASES RISK FOR MORTALITY IN DEPRESSIVE OLDER PEOPLE

T. Lyyra[1], T.M. Tormakangas[1], T. Van Tilburg[2], M. Aartsen[2], H.C. Comijs[2], M. Huisman[2], D.J. Deeg[2], *1. University of Jyväskylä, Jyväskylä, Finland, 2. VU Univerity and VU University medical centre, Amsterdam, Netherlands*

Background: It is well known that social support is related to the health of older people, but the mechanisms remain unclear. One of the theories proposes a stress-buffering mechanism, which we wanted to test by investigating the relationship between depression and mortality risk in those older people being emotionally lonely and those who are not. Material and methods: Data are from the Longitudinal Aging Study Amsterdam (LASA), a population based study, including 2013 subjects aged 65 and older at baseline in 1992/1993. Measures included the Center of Epidemiologic Studies Depression Scale (CES-D) and the de Jong Gierveld Loneliness Scale. Results: 32 % of the respondents reported feelings of emotional loneliness indicating their lack of social support. Depressive symptoms (CES-D>16) were found in 16 % of the sample. After 16-years follow-up, 13 % of the depressed group had died, and 24 of emotionally lonely group. Depressed older people perceiving emotional loneliness had a 1.3 times higher risk for dying (HR 1.32; 95% CI 1.09, 1.60) compared to those who were not depressed, adjusted for socio-demographics, physical and cognitive functioning and chronic illnesses. No association between depression and mortality was found among those without emotional loneliness. Conclusions: These findings suggest that absence of emotional loneliness, i.e., when people perceive to be socially supported and embedded, buffers against the risk for mortality in depressed older people. Depressed older people are a risk group and their need for social support should be taken into account in order to maintain their health and well-being.

### INFLUENCE OF SOCIAL ENVIRONMENT ON LONELINESS IN OLDER ADULTS: MODERATION BY POLYMORPHISM IN THE CRHR1A

K. Chou, *University of Hong Kong, Hong Kong, Hong Kong*

Both adverse social environments and genetic factors contribute to loneliness in old age. Mixed findings between the social relation with children and loneliness among older adults suggested that a gene x social environment interaction may be operating. We examine whether the effects of infrequent contact with children and/or low perceived social support from children on loneliness in older adults are moderated by two candidate single nucleotide polymorphisms (SNPs, namely rs1876831 and rs242938) in the corticotrophin releasing hormone receptor 1 (CRHR1) gene. To test this hypothesis, we focus on a sample of 1734 community-dwelling older adults aged 65 and above, interviewed in both 2003-2004 and 2006-2007 assessments of the English Longitudinal Study of Aging (ELSA). Our main outcome measure is loneliness which was assessed by four items extracted from ULCA loneliness scale. Compared with older adults carrying the CT/TT genotypes, individuals homozygous for the C allele of rs1876831 reported higher levels of loneliness in the context of infrequent social contact with children and low levels of perceived social support from children. No gene X social environment interactions were found for loneliness between rs242938 and adverse social environment related to children. This study provides the first evidence in humans that the CRHR1 gene interacts with exposure to a negative social environment to predict loneliness in older adults.

### DEPRESSION AND LONELINESS AMONG CHINESE OLDER ADULTS: FINDINGS FROM A CHINESE COMMUNITY NEEDS ASSESSMENT

E. Chang[1], M.A. Simon[2], E. Wong[3], B. Wong[3], X. Dong[1], *1. Rush Institute for Healthy Aging, Rush University Medical Center, Chicago, Illinois, 2. Northwestern University Medical Center, Chicago, Illinois, 3. Chinese American Service League, Chicago, Illinois*

Background: Despite an increased understanding on minority health in recent years, little is known about the health status among Chinese population, one of the fastest growing ethnic populations in the U.S. Vast knowledge gaps exist in assessing the psychological needs of Chinese immigrant elders. Methods: This cross-sectional study is part of the NIH-funded Partnering in Research project that explored depression and loneliness among older Chinese adults, aged 60 and over who reside in the Chinese community. Community-based participatory research approach was utilized to partner with key stakeholders in the Chicago Chinese community. Results: Among surveyed participants (N=78), the mean age was 74.8 and fifty-three percent was female. Mean education level was 10.7 years of schooling. With respect to depressive syndromes, 17% of participants often felt being bored, 21% of participants often felt helpless, 12% of participants reported dis-satisfied with life, 28% of participant preferred to stay home and 17% of participants reported feeling of worthless. With respect to loneliness, 42% of participants reported feelings of lacking companionship, 35% of participants felt being left of life and 30% of participants reported of feeling isolated. Conclusion: Symptoms of depression and loneliness are common in urban Chinese population. Future studies are needed to explore social and cultural context of these findings. Larger population-based study of risk and protective factors are needed to inform future prevention and intervention studies to improve the psychological well-being of this population.

### A CURRENT STATE OF THE SCIENCE ON LONELINESS AND THE HEALTH OF OLDER ADULTS

L.A. Theeke, *Health Restoration, WVU School of Nursing, Morgantown, West Virginia*

This paper presents an interdisciplinary perspective on the phenomenon of loneliness as it relates to the health of older adults. Loneliness is a prevalent negative experience, and a consistent predictor of physical symptoms, lower quality of life, psychological distress, and depression. Primary research studies from nursing, medicine, sociology, psychology, community health, and gerontology that examined loneliness and included older, community-dwelling adults in the study sample are included in this review. Fifty-four quantitative and five qualitative studies were analyzed to seek commonalities/differences in conceptualization of loneliness, measurement of loneliness, and health-related findings. Reviewed studies clearly came from each discipline's unique perspective but there were commonalities throughout the review. Prevalence of loneliness ranged from 12% to 38%. Loneliness consistently correlated with advancing age, poor perceived health, physical widowhood, poverty, low education, fewer social contacts, domestic violence, substance use, and lack of religious affiliation. Poor health, poor functional status, marital status, and social factors were predictive of loneliness. Outcomes associated with loneliness varied by age and culture. Loneliness has been primarily measured through the use of four instruments, The UCLA Loneliness Scale, The DeJong-Gierveld Scale, The Loneliness Questionnaire, and single-item self-report. The lack of consistency in measuring loneliness limits the ability to draw conclusions. Only six studies tested interventions aimed at diminishing loneliness, indicating a gap for evidence-based practice. Each discipline brings a unique perspective that may be important in designing and evaluating interventions for loneliness, further indicating that developing multidisciplinary teams to test interventions may advance the knowledge base related to loneliness.

### A META-ANALYSIS OF INTERVENTIONS TO REDUCE LONELINESS

C. Masi, H. Chen, L. Hawkley, J.T. Cacioppo, *University of Chicago, Chicago, Illinois*

Social and demographic trends are placing an increasing number of adults at risk for loneliness, which is associated with myriad health problems, including hypertension, diminished immunity, depressive symptoms, cognitive decline, and mortality. The growing costs associated with loneliness have led to a number of loneliness reduction interventions and several qualitative reviews have been published. These reviews have identified four primary intervention types: social skills training, enhancing social support, increasing access to social opportunities, and addressing maladaptive social cognition. A consensus exists that loneliness can be reduced using one or more of these intervention techniques. However, this perception has never been assessed quantitatively. Using Medline and PsycINFO, we searched the literature for intervention studies which measured loneliness quantitatively and were published in peer-reviewed journals between 1970 and 2009. Standard meta-analytical procedures were used to calculate mean effect sizes and to perform moderator analysis. A random-effects model was used due to the variety of interventions identified. Of the 928 studies originally identified, 50 met our inclusion criteria. Of these, intervention studies with less rigorous designs (e.g., single group pre-post analysis and non-randomized group comparisons) demonstrated greater mean effect sizes (-0.367, 95% C.I. -0.55, -0.18 and -0.459, 95% C.I. -0.72, -0.20, respectively) compared to the more rigorous randomized group comparisons (-0.198, 95% C.I. -0.32, -0.08). Moderator analysis of the randomized group comparisons revealed that interventions which addressed maladaptive social cognition were the most successful. These results have implications for future interventions, especially given our current understanding regarding the etiology and nature of loneliness.

## SESSION 15 (SYMPOSIUM)

### OLDER ADULTS' COGNITIVE BELIEFS AS SOCIAL-PSYCHOLOGICAL ANTECEDENTS OF SUBJECTIVE HEALTH

Chair: *P.S. Fry, Graduate Psychology, Trinity Western University, Langley, British Columbia, Canada*
Discussant: *P. Martin, Iowa State University, Ames, Iowa*

To date, one of the most understudied etiologies of older adults' well-being has been the role of their cognitive beliefs and worldviews that interact with their functional capacity to maintain or diminish a consistent sense of self and well-being. Given what we already know about factors contributing to older adults' vulnerability, the aim of the present proposal is to investigate a selective set of older adults' cognitive beliefs that are hypothesized to offset threats to their well-being,and are linked to maintaining a stable sense of subjective well-being in relation to daily functioning and to strengthening the pursuit of self-enhancement activity. Thus, for example, Fry & Debats' longitudinal research findings demonstrate that older adults' strong cognitive "beliefs in a just world" are correlated positively with feelings of competence and optimism about the future. Cox regression analyses show that "beliefs in a just world" are a psychological predictor of longevity. Similarly, Silton et al.'s research findings show the significant role of beliefs about forgiveness in the context of daily functioning. Overall, forgiveness appeared to have an indirect salutary effect on subjective health through its negative association with hostility. Findings support the notion that forgiveness may serve an indirect health benefit by reducing hostility. Jopp et al.'s study demonstrates the positive influence of older adults' beliefs about personal control on subjective health. Collectively the papers highlight the role of cognitive beliefs and self-beliefs as social-psychological antecedents that possibly reduce threat to age-related decline, and are linked with older adults' increased subjective well-being.

### OLD ADULT'S BELIEF IN A JUST WORLD AS A PREDICTOR OF HEALTHY LONGEVITY: A LONGITUDINAL ANALYSIS

P.S. Fry[1], D.L. Debats[2], *1. Graduate Psychology, Trinity Western University, Langley, British Columbia, Canada, 2. Private clinical practitioner, Groningen, Netherlands*

One of the most understudied etiologies concerning the well-being of older adults has been the contribution of individuals' cognitive beliefs to maintaining or diminishing a stable sense of subjective well-being and health. The aim of this study was to determine the extent to which older adults' self-sustained cognitive belief in a just world is related to their self-rated health and long-term subjective well-being and longevity. The theoretical premise is that individuals' with a strong belief in a just world are able to deal more resiliently with negative life-events that may threaten their well-being. After baseline assessment of health, subjective well-being and cognitive belief in a just world, 450 older adults were followed longitudinally over 7.5 years. A major hypothesis was that individuals' strength of belief in a just world is an early and predictive indicator of healthy longevity. Cox regression analyses confirmed the hypothesis. Implications for healthy longevity are discussed.

### CONTROL BELIEFS IN OLDER AGE: TRAJECTORIES AND PREDICTIVE VALIDITY

D.S. Jopp[1], M. Schmitt[2], *1. Psychology, Fordham University, Bronx, New York, 2. Dortmund University, Dortmund, Germany*

The study investigates trajectories of control beliefs in older individuals and their links to well-being and health. We assessed 501 older adults (mean age = 62) at two measurement occasions 11 years apart. Internal control beliefs regarding positive events remained stable as did chance beliefs. Internal control over negative events decreased, but beliefs about powerful others increased. Regressions included control scales at both measurement points, objective health, perceived age-related changes and an auto-regressive term. Life satisfaction (T2) was predicted by internal control over negative events at T1, objective health and life satisfaction at T1: Higher responsibility for negative events went along with lower life satisfaction. Subjective health was predicted by powerful others (T1) and internal control over positive events (T2), objective health, age-related changes and subjective health (T1). In sum, findings suggest long-term effects of control beliefs on successful aging outcomes with differential effects for life satisfaction and subjective health.

### FORGIVENESS, HOSTILITY, AND SUBJECTIVE HEALTH

N.R. Silton, K.J. Flannelly, K. Galek, L.T. Flannelly, *Healthcare Chaplaincy, New York, New York*

The relationships among age, forgiveness, hostility and subjective health were examined in a sample of 1327 U.S. adults who completed a web-based survey sponsored by Spirituality and Health magazine. Participants responded to questions pertaining to (a) age, (b) forgiveness towards those who hurt you, (c) a hostility scale related to engaging in specific behaviors, and (d) a four-item general health scale from the Short-Form 36. A structural equation model revealed that older participants were more likely to forgive those who hurt them ($p<.001$) and to have lower subjective health ($p<.001$). The model indicated an inverse relationship between forgiveness and hostility ($p<.01$) and a strong inverse relationship between hostility and subjective health ($p<.001$). Overall, forgiveness appeared to have an indirect salutary effect on subjective health through its negative association with hostility ($p<.001$). The findings thus support the notion that forgiveness may serve an indirect health benefit by reducing hostility.

## SESSION 20 (SYMPOSIUM)

### RESILIENCE AND POSITIVE ADAPTATION ACROSS THE LIFESPAN

Chair: *C.M. Aldwin, Oregon State University, Corvallis, Oregon*
Co-Chair: *M. Ardelt, Sociology and Criminology & Law, University of Florida, Gainesville, Florida*
Discussant: *A. Spiro, Boston University, Boston, Massachusetts*

Adaptation of positive psychology constructs to adult development and aging has provided interesting insights into optimal aging. The present symposium addresses four of those constructs, resilience, wisdom, stress-related growth (SRG), and social support, in samples ranging from adolescence through late life. The first two papers address wisdom. Ardelt and her colleagues found that generativity was related to positive psychological outcomes only among individuals with high combat exposure in WWII, suggesting the SRG combines with adult development in mid-life to promote wisdom and well-being in late life. The article by Lee et al. examines cross-cultural differences in wisdom, and found that age is not related to self-transcendent wisdom in a US sample, but was positively related in a Korean sample, suggesting that culture may also influence the course of adult development. The paper by Bi and her colleagues found that age was not directly related to SRG, but was indirectly related through stressor characteristics. Middle-aged adults were more likely to experience chronic stress and use positive action coping than younger adults, which in turn were related to increases in SRG over time. The last two studies focused on social support. The paper by Trask-Tate and her colleagues found that resilience among African American adolescents was influenced by parental social support, and Toyokawa and her colleagues found that being married was a strong predictor of the maintenance of social connectivity in late life. Thus, adult development and well-being is influenced by the sociocultural context and by how well individuals cope with stress.

### THE LONG-TERM EFFECTS OF WWII COMBAT ON LATER LIFE WISDOM AND WELL-BEING MODERATED BY GENERATIVITY

M. Ardelt[1], S.D. Landes[1], G.E. Vaillant[2], *1. Sociology and Criminology & Law, University of Florida, Gainesville, Florida, 2. Brigham and Women's Hospital, Boston, Massachusetts*

According to theories of stress-related growth, coping with traumatic events can lead to greater psychosocial maturity in resilient individuals or psychosocial maladjustment in less resilient individuals. Using a sample of 217 World War II veterans of the 60-year longitudinal Study of Adult Development, the research examined the long-term effects of high, low, and no combat exposure among Harvard educated white men who either achieved or failed to achieve Erikson's psychosocial developmental stage of generativity at midlife. Findings revealed that the effect of generativity on physical health, psychological distress, wisdom, and well-being in midlife and old age differed by level of combat exposure during WWII. Although combat exposure was unrelated to the outcome variables, only among veterans with high combat exposure was generativity consistently positively related to physical and psychological health, wisdom, and well-being. The results indicate a resiliency effect for men with high combat exposure who experienced subsequent psychosocial growth.

### CROSS-CULTURAL COMPARISON OF SELF-TRANSCENDENCE AND ALIENATION IN UNITED STATES AND KOREAN SAMPLES

S. Lee, S. Choun, M. Levenson, *Human Develoment and Family Sciences, Oregon State University, Corvallis, Oregon*

We compared self-transcendence and alienation in the United States and Korea. Our analyses utilized two samples, one from the United States (N = 348) and another from Korea (N = 872). Self-transcendence and alienation were measured with the Adult Self-Transcendence Inventory (Levenson, Jennings, Aldwin, & Shiraishi, 2005). Regression analysis demonstrated that self-transcendence was significantly related to age, gender, and religion in the Korean sample while alienation was significantly related negatively to religion in the US sample. Results from ANCOVA suggested that self-transcendence in the Korean sample was significantly higher than in the US sample, and adults over age 40 were higher than younger adults (20 to 39). Interaction of the age and culture was significant; self-transcendence was significantly related to age in the Korean sample whereas not related to age in the US sample. These findings suggest that age is differently related with self-transcendence between the two cultures.

### AGE AND SEX AS PREDICTORS OF CHANGE IN STRESS-RELATED GROWTH: FINDINGS FROM THE DAVIS LONGITUDINAL STUDY

X. Bi, A.L. Taylor, D.L. Romo, *Oregon State University, Corvallis, Oregon*

Stress-related growth (SRG; Park, 2009) is characterized by changes in values, mastery, coping skills, spirituality, and resources (Tedeschi & Calhoun, 2004), similar to some models of adult development (Aldwin et al., 2007). However, the developmental aspects of SRG have received little empirical investigation. Data from the Davis Longitudinal Study (1996 and 2001) were used to examine whether age, sex, and SRG at 1996 predicted stressor characteristics and SRG at 2001 among 621 college alumni (Mage=44.36, SD=7.11, 45.97% male). SEM analysis indicated that age in 1996 had no direct effects on SRG, but positive indirect effects on change in SRG via duration of stressor and positive coping. Older individuals experienced more chronic stress and used more positive coping, which led to higher SRG levels. Women were more likely to report SRG at both time points. Developmental change in adulthood depends on both stressor and personal characteristics, as well as coping efforts.

### THE IMPORTANCE OF FAMILY: THE IMPACT OF SOCIAL SUPPORT ON PSYCHOLOGICAL DISTRESS IN AFRICAN AMERICAN ADOLESCENTS

A. Trask-Tate, M. Cunningham, L. Lang-Degrange, *Department of Psychology, Tulane University, New Orleans, Louisiana*

The study examines social support and ego resiliency as buffers for the development of psychological distress in a population of urban African American female adolescents. The participants were 136 high school students ranging from 14 – 19 years of age (M = 16.02 years, SD = 1.10) who resided in a large southern city. Students completed measures examining negative life events, social support, ego resiliency, and depressive symptoms. While the perceptions of social support from mothers were highest of all domains of support, girls with lower levels of ego resiliency experienced fewer depressive symptoms when perceptions of social support from fathers were high. Additionally, the results indicate that resilience in African American female adolescents is associated with the combination of supportive family relationships as well as the ability to adjust to new and challenging environmental demands.

### DOES MARITAL STATUS AFFECT CHANGE IN SOCIAL RELATIONS IN LATER LIFE? FINDINGS FROM THE NORMATIVE AGING STUDY

N. Toyokawa[1], S. Kang[1], A. Spiro[2], C.M. Aldwin[1], *1. Oregon State University, Corvallis, Oregon, 2. Boston University, Boston, Massachusetts*

Socioemotional selectivity theory (Carstensen et al., 2006) hypothesizes that there is a normative decline in network size and frequency of contact, but this theory has rarely been tested longitudinally, nor have individual differences been examined. 842 Normative Aging Study men (Mage=60.59, SD=7.52, range 41-86) were surveyed in 1985, 1988, and 1991. A repeated measures ANOVA revealed significant effects of time, marital status, and age group for frequency of contact with family and close friends. Men older than sixty and unmarried men did have less social contact. None of the interaction effects with time reached significance in the multivariate model. However, contrasts showed that the time effect was quadratic, $F(1, 838) = 3.91$, $p < .05$ (an inverted U), with a marginal status * time effect, $F(1,838) = 3,69$, $p = .055$. Married men were more likely to decline in frequency of contact. Results suggest both period and individual differences effects.

## SESSION 25 (SYMPOSIUM)

### SPOUSAL INTERRELATIONS IN COGNITION, HEALTH, AND WELLBEING IN OLD AGE: EVIDENCE FROM DAILY TIME-SAMPLES AND LONG-TERM LONGITUDINAL STUDIES

Chair: *C. Hoppmann, University of British Columbia, Vancouver, British Columbia, Canada*

Co-Chair: *D. Gerstorf, The Pennsylvania State University, College Park, Pennsylvania*

Discussant: *M. Luszcz, Flinders University, Adelaide, Western Australia, Australia*

Development takes place in the context of close others such as marital partners. This may be particularly true in old age when network size typically decreases and spouses share a long history of joint experiences. This symposium examines spousal interrelations in three domains of functioning that are key for successful aging: Cognition, health, and wellbeing. Specifically, it brings together couple research examining the dynamic interplay between spousal functioning using daily-process approaches and long-term longitudinal methods. Berg and colleagues investigate the relationship between problem anticipation, negative affect, and problem solving effectiveness using daily-diary information from couples where one spouse is diagnosed with prostate cancer. They draw attention to dynamic associations in daily-life processes across domains of functioning. Hoppmann and colleagues examine the interplay between spousal well-being and health trajectories using long-term longitudinal couple data from the national sample in the AHEAD study. They show that well-being and health in old age influence and are influenced considerably by the respective spouse. Windsor and colleagues examine spousal associations in life-satisfaction trajectories in three groups of couples in the national Australian HILDA study. Their findings indicate that relationship history is differentially associated with spousal interrelations in life satisfaction trajectories in young as compared to older couples. Martin and colleagues use data from several dyadic data collection paradigms to demonstrate the adaptive value of dissimilarities between spousal partners. The discussion by Mary Luszcz focuses on the potentials of examining socially interrelated aging trajectories in the context of marital relationships and addresses the challenges that this line of research has to confront.

### PROBLEM ANTICIPATION AND DAILY ADJUSTMENT IN COUPLES COPING WITH PROSTATE CANCER

C.A. Berg[1], D.J. Wiebe[2], J. Butner[1], *1. Psychology, University of Utah, Salt Lake City, Utah, 2. University of Texas Southwestern Medical Center, Dallas, Texas*

The ability to predict daily stressful events among couples dealing with prostate cancer was examined and whether problem anticipation related to daily adjustment. Fifty-nine husbands and wives completed diaries for 14 days reporting stressful events, whether they anticipated those events, controllability of the events, negative affect, and efficacy in dealing with the event. Hierarchical Linear Modeling revealed that greater problem anticipation was associated with lower same day negative affect and greater efficacy to deal with events, by both husbands and wives, even when controlling for problem controllability and stressfulness of the event. Although there were same day associations between husband and wife problem anticipation (on days when husbands anticipated problems, wives were more likely to anticipate problems), problem anticipation by one spouse did not predict adjustment in the other spouse. The results show that although daily experiences with stressors are linked within couples, such links do not always predict cross-spouse adjustment.

### SPOUSAL INTERRELATIONS IN DEPRESSIVE SYMPTOMS AND FUNCTIONAL LIMITATIONS: LONGITUDINAL FINDINGS FROM THE STUDY OF ASSET AND HEALTH DYNAMICS AMONG THE OLDEST OLD (AHEAD)

C. Hoppmann[2], D. Gerstorf[1], A. Hibbert[2], *1. Department of Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania, 2. University of British Columbia, Vancouver, British Columbia, Canada*

This study extends previous research on wellbeing-health associations that use samples of unrelated individuals by examining spousal interrelations in aging trajectories across these key domains of functioning. We use 14-year longitudinal data on depressive symptoms and functional limitations from 1,704 couples in the AHEAD Study. Structural equation models corroborate previous individual-level findings that levels and changes in depressive symptoms and functional limitations are closely interrelated. Importantly, our results also highlight sizeable associations of levels and changes in depressive symptoms and functional limitations between spouses. For example, increases in depressive symptoms in one spouse were accompanied by increases in depressive symptoms and functional limitations in the other spouse. The associations found were not different between men and women and remained after controlling for potential covariates (age, education, cognition, length of marriage, number of children). Our findings support an interactive minds perspective, which proposes that aging is linked in social relationships.

### SPOUSAL INTERRELATIONS IN TRAJECTORIES OF LIFE SATISFACTION: A COMPARISON OF YOUNGER RECENTLY MARRIED, OLDER RECENTLY MARRIED, AND OLDER LONG-TERM MARRIED COUPLES

T. Windsor[1], D. Gerstorf[2], C. Hoppmann[3], P. Butterworth[1], *1. The Australian National University, Canberra, Australian Capital Territory, Australia, 2. The Pennsylvania State University, State College, Pennsylvania, 3. University of British Columbia, Vancouver, British Columbia, Canada*

Spousal relationships represent important social contexts for well being. This study considered age differences in social motivation, and shared experience linked to relationship duration, as mechanisms underlying spousal interrelations in life satisfaction. Spouses' trajectories of life satisfaction were modeled over a seven-year interval using population data from the Australian HILDA study. Analyses contrasted younger recently married couples (n = 826), older recently married couples (n = 93) and older long-term married couples (n = 1102). Unadjusted models showed spousal interrelations in initial levels and subsequent changes in life satisfaction were strongest among older, long-term married couples. Spousal similarities in life satisfaction were significant among younger recently married couples; however the association for initial level was weaker relative to the older long-term married group. Spouses' life satisfaction ratings were unrelated among the older recently married adults. Results are discussed in the context of implications for re-partnering in middle and older adulthood.

### IS BECOMING MORE DIFFERENT BETTER FOR BOTH: HOW INTRADYADIC DIFFERENCES ARE RELATED TO INDIVIDUAL DEVELOPMENT IN OLD AGE

M. Martin, M. Peter-Wight, R. Hornung, G. Bodenmann, *Psychology, University of Zurich, Zurich, Switzerland*

Several studies have demonstrated that our understanding of individual development in old age can be improved when considering how intradyadic adaptation processes may lead to an adaptive increase in differences between the partners. Counterintuitively it may be positive for goal achievement and autonomy if individuals within dyads reduce individual performance and autonomy. We present a conceptual model of dyadic development in old age suggesting how the intradyadic orchestration of individual development may stabilize quality of life despite individual losses of functioning. We present data from several longitudinal studies demonstrating the adaptive effects of increasing intradyadic differences. These include dyadic problem-solving, dyadic memory, dyadic personality differences, dyadic well-being, and dyadic adaptation to dementia.

## SESSION 30 (SYMPOSIUM)

### DIFFERENCES IN STROKE CARE SETTINGS: FINDINGS FROM THE PATIENT PREFERENCE FOR STROKE STUDY

Chair: *P. Gregory, Physical Medicine and Rehabilitation, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*
Discussant: *A.C. Felix, Physical Medicine and Rehabilitation, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

Stroke is a catastrophic illness that involves a number of transitions in care during the recovery process. Maximizing recovery involves understanding a number of factors that influence the recovery process. These factors include both individual patient factors and institutional care delivery factors. The patient's level of pre-morbid physical activity will influence the risk for stroke as well as the potential for functional recovery. The available resources at the hospital they are admitted may influence their access to stroke care services. And the patients' personal preferences for stroke rehabilitation services will influence their treatment choices. The Patient Preferences for Stroke Study was an observational survey of 53 patients admitted to two hospitals, a primary stroke center (PSC) and a rural community hospital (RCH), in the stroke belt. Participants were surveyed during their acute stroke hospitalization, prior to discharge. Data collection included basic demographics, pre-morbid physical activity, and patient preferences for rehabilitation. "The Self-Reported Physical Activity of Patient Preferences Study Participants" will describe the physical activity of participants and factors associated with activity level. The "Hospital Differences in Stroke Care" compared the differences in available resources at the PSC and RCH in the Patient Preference for Stroke Study. "Treatment Preference for Initial Rehabilitation" describes the stroke patients' preference for initial rehabilitation therapy setting during the acute hospitalization. A better understanding of how stroke care differs at two separate institutions will help identify areas for interventions to improve access to stroke care.

### PHYSICAL ACTIVITY AS A RISK FACTOR FOR STROKE

P. Gregory, K.R. Faurot, D. Urlaub, P.E. Sweat, L. Edwards, *Physical Medicine and Rehabilitation, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

Physical activity is a risk factor for stoke and cardiovascular disease. The Behavioral Risk factor Surveillance System (BRFSS) reported the lowest levels of physical activity among minorities that historically have a greater prevalence and severity of stroke. Prior studies of physical activity among stroke patients studied predominantly white populations. We evaluated the self-reported physical activity levels among stroke patients enrolled in the Patient Preference for Stroke Study. This study evaluated the care at two hospitals a primary stroke center and a rural community hospital. Participants included a large percentage (47%) of minority patients. Results showed the mean physical activity of participants was 69.3 metabolic equivalents (METS). Participants with lower METS scores were more likely to be older Odds Ratio (OR) 8.24 95% Confidence Interval (95% CI) 2.02, 33.71, female OR 4.25 95% CI 1.10, 16.49, and hospitalized at the RCH OR 4.99 95% CI 1.07, 23.36.

### HOSPITAL DIFFERENCES IN STROKE CARE

K.R. Faurot, P. Gregory, D. Urlaub, P.E. Sweat, *Physical Medicine & Rehabilitation, UNC, Chapel Hill, North Carolina*

Although stroke often leads to long-term disability, early intensive rehabilitation can maximize functional recovery. However, access to rehabilitation therapies varies by hospital setting. Primary stroke centers (PSC), designated by JCAHO, provide evidence-based quality stroke care, but rural community hospitals (RCH) often have limited resources to provide stroke recovery services. This observational cross-sectional study compared rehabilitation services data from a PSC and an RCH. After controlling for possible confounders, results revealed that patients at the PSC had eight times the odds of receiving a speech and language pathology evaluation compared to the RCH: Odds Ratio (OR) 8.62 [95% Confidence Interval (95% CI) 1.91, 38.95]. Patients at the PSC were also less likely to be minority: OR 0.16 [95% CI 0.03, 0.74]. Results of this investigation identify areas of focus for interventions to increase stroke quality of care.

### PATIENT PREFERENCES FOR STROKE REHABILITATION

S.W. Williams, P. Gregory, K.R. Faurot, D. Urlaub, P.E. Sweat, *Physical Medicine and Rehabilitation, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

Stroke is often a chronic illness that involves transitions across different care settings, including acute, sub-acute, and chronic care settings. While stroke severity, patients' ability to participate in rehabilitation care, available local resources, and financial resources are associated with initial rehabilitation setting, the role of patient preferences has not been carefully evaluated in the acute care setting. Therefore, the Patient Preferences for Stroke Study evaluated the preferences of stroke patients for an initial rehabilitation setting. Overall, 85% of participants preferred their initial rehabilitation setting to be in their home. Preference for home was associated with an actual discharge destination to the patient's home (Odds Ratio 7.19 95% Confidence Interval 1.10, 46.89), after controlling for other factors. Since many factors influence rehabilitation discharge destination, understanding what patients prefer for rehabilitation settings may help guide providers who are coordinating care and counseling patients and families regarding the best options for stroke rehabilitation.

## SESSION 35 (SYMPOSIUM)

### INNOVATIVE STRATEGIES IN RESPONSE TO TRANSITIONAL HEALTH CARE NEEDS OF OLDER ADULTS

Chair: *S.Y. Hawkins, Yale University School of Nursing, New Haven, Connecticut*

Discussant: *D.K. Pastor, Molloy College, Rockville Centre, New York*

Older adults and their caregivers experience transitions of care throughout the continuum of health and behavioral health care. Often, these transitions occur when older adults require a necessary change in type of care or services due to their changing health care status. These changes may result from a newly-established diagnosis, need for different level of care, developmental changes, and/or accessibility challenges to health care. Innovative strategies are essential to make these transitions successful so that health and well-being are optimized with these older adults. Nurses play an integral role in improving health care outcomes of older adults by conducting research on these various needs or services, and testing their efficacy or effectiveness by incorporating evidence-based interventions into their practice. The purpose of this symposium is to explore research that utilizes innovative strategies when transitions occur in older adults to promote positive health outcomes. One presenter in this symposium will analyze a wellness program initiated with a group of nuns to facilitate their transition into older adulthood. Two other presenters will explore developing and delivering educational programs, one to older adults with diabetes in their homes and the other to nurse practitioners working in nursing homes, to enhance patient and provider knowledge respectively. Another presenter will examine the feasibility of using acupuncture for agitation behaviors in older adults with dementia. All of these papers represent research directly with older adults with implications for nursing practice that have been conducted by participants of the Hartford Institute for Geriatric Nursing Scholars Program.

### TRANSITIONING CARE: OLDER ADULTS USING VIDEOPHONES FOR DIABETES SELF-MANAGEMENT

S.Y. Hawkins, *Yale University School of Nursing, New Haven, Connecticut*

Aims: The purpose of this study was to evaluate whether a videophone motivational interviewing (MI) diabetes self-management education (DSME) intervention would improve glycemic control of rural older adults. Methods: This pilot study was a two-group pre-test, post-test design. A convenience sample of diabetic adults aged 60 years and over was enrolled. Experimental participants (n=34) received weekly, then monthly, videophone MI DSME calls while attentional control participants (n=32) received monthly healthy lifestyle education calls. Results: There were 66 participants in the study, average age 64.9 years. Both groups experienced a decreased HbA1c but there was a significant difference in the experimental group (p=.015) but not the control group (p=.086). The experimental group demonstrated significant increases in diabetes knowledge (p=.023), diabetes self-efficacy (p=.002), and stage of change (p=.040). Conclusions: Older adults can become motivated and empowered to perform diabetes self-management by using a videophone MI DSME intervention delivered into their homes.

### DEVELOPING AND DELIVERING ONLINE PALLIATIVE CARE EDUCATION FOR NPS IN NURSING HOME SETTINGS

M. Letizia, *Loyola University Chicago, Maywood, Illinois*

The nursing home is a major setting for death and dying in the United States, yet palliative care approaches are underused in these facilities. While Nurse Practitioners working in nursing homes are well-suited to provide this care, most have not received formal education about this specialty practice. This session describes the processes involved in developing and implementing an online Palliative Care course intended to better prepare Nurse Practitioners across the country to direct and deliver high-quality palliative care to patients and families in nursing home settings.

### PHYSICAL PERFORMANCE, HEALTH STATUS, MOOD, AND RESILIENCE IN OLDER NUNS

M. Wells, D. Avers, G. Brooks, *SUNY Upstate Medical University, Syracuse, New York*

Purpose: As Catholic nuns retire from active vocation, they often become less socially and physically active. A wellness program was initiated with a group of nuns to facilitate their transition into older adulthood. The aim of this analysis was to determine if there were relationships between physical performance and self-reported health indicators in nuns 55 years and older. Method: Cross-sectional data were collected from 58 nuns. Physical performance was measured with the Short Physical Performance Battery (SPPB). Self-reported measures included weekly aerobic activity, mood, physical and mental health status, and resilience. Spearman correlations assessed relationships among the outcomes measured. Findings: Physical performance was associated with mood and physical health status, but not with aerobic activity, resilience or mental health status. Conclusion: Nuns with higher physical performance scores also tended to have better self-reported mood and physical health. Amount of self-reported aerobic activity was not related to physical performance.

### THE USE OF ACUPUNCTURE TREATMENT FOR PEOPLE WITH DEMENTIA RELATED AGITATION BEHAVIORS

L. Struble, R. Harris, R. Sousley, *University of Michigan, Ann Arbor, Michigan*

Aims: In this pilot project we examined the effectiveness and feasibility of Chinese needle acupuncture treatments in people with dementia and agitation behaviors. After attending this session participants will be able to discuss the potential therapeutic applications of acupuncture treatments in this population. Methods: Seven subjects (average age 90) from one assisted living facility with a diagnosis of dementia (average MMSE score of 12) received 12 acupuncture treatments in 6 weeks and retained 14 needles for 20 minutes during each session. Results: There were no adverse side effects from the treatments; most participants expressed some level of enjoyment, satisfaction and/or relaxation with the procedure; small reduction in agitation behaviors was found. Conclusions: Acupuncture treatments are safe however future research is needed with a larger sample to determine whether this intervention can have an impact on this stressful dementia related behavioral issue.

## SESSION 40 (PAPER)

## DEMENTIA - SRPP PAPER SESSION

### THE SOCIAL CONSTRUCTION OF DEMENTIA: PERSPECTIVES FROM ELDERLY PEOPLE WITH DEMENTIA AND THEIR FORMAL AND INFORMAL CAREGIVERS

S. Torres, I. Hellstrom, *NISAL, Linkoping University, Norrkoping, Sweden*

Understandings the different perspectives that people may have on what dementia entails and how it affects everyday life are needed in gerontological practice. In order to advance the formulation of suitable interventions for people with dementia and their informal caregivers we need to understand how the social construction of dementia is shaped and the manner in which this construction relates to understandings of diminished everyday competence and dependency. This presentation departs from a project that aims to shed light on the variety of ways in which dementia can be understood. The data is constituted of 50 semi-structured qualitative interviews (21 with people with dementia, 22 with their informal caregivers and 7 with their formal caregivers) conducted on the basis of the emotionalist tradition. The analysis shows that – with the exception of the formal caregivers – most informants seem to compartmentalize their understandings of dementia in such a way as to allow them to draw attention to either the resources needed (as in the case of the informal caregivers) or to the resources they still have (as in the case of the patients). Alluding to dementia as single symptoms as opposed to an illness made it possible for the different informants interviewed to achieve contradictory goals. The analysis shows also that although the studied social constructions of dementia took for granted that future diminished everyday competence and increased dependency upon others were a given they were also characterized by an optimistic outlook on the future.

### JUSTIFICATION OF INVESTING IN ALZHEIMER'S RESEARCH

S. Shen, L. Alecxih, *The Lewin Group, Falls Church, Virginia*

Alzheimer's is a major cause of later life disability and requires unique efforts for care and transitions planning. As baby boomers age, Alzheimer's will become more prevalent and will become a painful burden for millions of families. In addition to no treatment to stop or delay development, scientific opportunities are stalled by minimal investment in the disease. One reason for minimal Alzheimer's scientific investment is that little has been done on the cost-saving impact of Alzheimer's research. The Alzheimer's Delay Impact 2050 model simulates this potential impact of treatment research through year 2050 on the number of individuals with Alzheimer's; healthcare expenditures; cost of drugs; and return on investment of treatment breakthroughs. Based on Census, Medicare Current Beneficiary Survey, and prevalence data, the model simulates number who die of or develop Alzheimer's; transitions in disease severity; and delay, costs, and savings of drug breakthroughs. Assuming a new treatment breakthrough in 2020 with a 25% take-up rate, the model predicts that Alzheimer's will affect 10% of older adults. Alzheimer's spending could total $702 billion in 2050 (2005 dollars), from $92 billion in 2005. However, a treatment breakthrough could result in $429 billion savings over 2020-2050. As Alzheimer's has serious consequences for individuals, families, and healthcare systems, projections under different scenarios are important for planning the future needs of the aging population. The Alzheimer's Delay Impact 2050 can help policymakers allocate research resources to biomedical and pharmaceutical projects and development of care transitions models and programs tailored for Alzheimer's patients and families.

### A COMPARATIVE ANALYSIS OF FAMILY CAREGIVERS OF PATIENTS WITH ALZHEIMER'S DISEASE AND SPINAL CORD INJURED SURVIVORS

D.M. Perdomo[1], S. Czaja[1], R. Schulz[2], *1. Center on Aging, University of Miami Miller School of Medicine, Miami, Florida, 2. Center for Social and Urban Research, University of Pittsburgh, Pittsburgh, Pennsylvania*

As Americans grow older their risk for functional impairments and chronic illnesses also increases, thus placing a greater burden on families. Because the caregiving experience is unique to each caregiver, it is important to examine the caregiving experience within the context of specific diseases and disabilities. This study examined the differences in care dynamics between family caregivers of Alzheimer's disease (AD) (N = 193) and spinal cord injured (SCI) persons (N = 96). The findings revealed differences in demographic characteristics, care experiences, psychological, physical and social functioning, religious/spiritual coping and risk factors between these two caregiver groups. Caregivers of AD patients were older, reported greater caregiving challenges, less social support, and were at greater risk for symptoms of depression and burden, health problems and being socially isolated than SCI caregivers. The implications of these findings for the design of caregiver intervention programs and for clinician training will be discussed.

### TRANSITIONS IN DEMENTIA CARE: REVIEW OF INTERNATIONAL POLICIES

M. Downs[1], R. Fortinsky[2], *1. University of Bradford, Bradford, United Kingdom, 2. Connecticut Centre on Aging, Farmington, Connecticut*

Background: Growth in the number of people with dementia is a worldwide phenomenon. Increasingly governments throughout the world are developing dementia–specific policies and strategies. Within the past decade, Australia, England, France, Netherlands, Norway and Scotland have developed dementia–specific strategic plans. Purpose: The purpose of this paper is to review similarities and differences in these plans in the extent to which they address transitions in care for people with dementia and their families. Method: A content analysis of dementia-specific strategic plans from Australia, England, France, Netherlands, Norway and Scotland was conducted. Results: There are many similarities across countries in their policies' broad principles and objectives. There are notable differences in the extent to which national dementia strategies address transitions in care. While all place significant emphasis on the initial transition to receiving a diagnosis of dementia, relatively few are concerned with addressing key transitions such as receipt of community-based services or entry in to long-term care. Discussion: As dementia knows no boundaries, there is a compelling argument for international cooperation and dialogue. 'International harmonization" of transitions in dementia care, analogous to "harmonization" of pharmacotherapy, is timely and rational to improve the practices of both dementia diagnosis and management worldwide. While some evidence is available to support these policy positions, much more evidence is needed to refine the ways in which transitions in dementia care might be coordinated.

### CULTURAL TRAUMA IN THE CONTEXT OF DEMENTIA: ADAPTATION AND RESISTANCE IN JEWISH AND INDIGENOUS COMMUNITIES

W. Hulko[1,2], L. Stern[2,3], *1. Social Work, Thompson Rivers University, Kamloops, British Columbia, Canada, 2. University of British Columbia, Vancouver, British Columbia, Canada, 3. The Louis Brier Home and Hospital, Vancouver, British Columbia, Canada*

There has been a growing interest over the past decade in the dementia experiences of individuals who belong to ethnic minority and racialized communities, as well as more recent efforts to conceptually clarify the cultural concept within dementia research. Cultural trauma is a neglected issue within this emerging body of work, however. Concerted attention to cultural trauma in relation to specific communities, such as Jewish and Indigenous peoples, can bring greater attention to people with dementia as members of and embedded within communities with distinct socio-cultural histories and shared experiences of cultural trauma. This paper draws on two separate qualitative research studies conducted in British Columbia, Canada: 1) sharing circles and interviews with Indigenous Elders from three communities belonging to the Secwepemc [Shuswap] Nation, and 2) Dementia Care Mapping, interviews and participant observation within a Jewish long-term facility. Cultural trauma has impacted these communities in both similar and different ways. The paper's analysis focuses on the ways in which both Jewish and Indigenous communities use adaptation and resistance as strategies to make sense of dementia and to access support and care services for community members living with dementia. The insights in this paper on cultural trauma can assist dementia care providers to adopt more culturally safe care practices, and encourage persons with dementia and their communities to make greater use of dementia care resources and services.

## SESSION 45 (SYMPOSIUM)

### THE SOCIAL WORK WORKFORCE IN NURSING HOMES: SETTINGS, ROLES, RESPONSIBILITIES AND SATISFACTION

Chair: *D. Gammonley, School of Social Work, University of Central Florida, Orlando, Florida*
Discussant: *P.D. Allen, Louisiana State University, Baton Rouge, Louisiana*

Recent scholarship has identified serious concerns related to the adequacy of social work staffing levels, provider qualifications, workload, and psychosocial care quality in nursing homes. This symposium reports on further progress made to identify key organizational and employee characteristics of the workforce. The first objective is to examine specific nursing home settings, roles and responsibilities as perceived by social workers and administrators, and factors contributing to job satisfaction. First, an organizational level analysis of staffing characteristics derived from institutional theory (DiMaggio & Powell, 1983) is applied to further understanding of the social work workforce in hospital-affiliated homes. The second study presents evidence illustrating how staffing, in addition to workplace relationships and perceived autonomy, contributes to job satisfaction among nursing home social workers. The perspectives of both nursing home social workers and administrators are reported in the next two papers which consider how administrators value social workers in nursing homes and how this affects work responsibilities as well as recruitment and retention. The final paper explores professionalization, specifically licensure as a social worker, and how it impacts roles, responsibilities, and satisfaction among gerontological social workers who work in nursing home and non-nursing home settings. As a second objective the discussant and panelists will address ways the findings from these workforce studies can be used to advocate for quality social services staffing in nursing homes, identify promising theoretical frameworks for research on improving the social work workforce in nursing homes.

### THE INFLUENCE OF HOSPITAL AFFILIATION AND PAYER STATUS ON SOCIAL SERVICES STAFFING IN NURSING HOMES

D. Gammonley[1], N.J. Zhang[2], S. Paek[2], M. Mason[2], *1. University of Central Florida, Orlando, Florida, 2. UCF Public Affairs Doctoral Program, Orlando, Florida*

Certified nursing homes must provide social services but vary in the employment of qualified staff. Discharge needs may lead hospital-affiliated facilities and homes serving more Medicare patients to have a different staffing profile. Guided by institutional theory we examined how status as a hospital-based facility and Medicare payer mix influenced qualified staffing. Using 2007 certified homes larger than 120 beds (N = 4,141) and Online Survey Certification and Reporting and Area Resource File data a retrospective, cross-sectional study was conducted with general linear regression modeling. Staffing was measured as skill mix and the ratio of qualified staff to residents. Hospital-based homes and homes with higher proportions of Medicare residents have a higher ratio of qualified social services staff to residents. Facilities with higher Medicare payer mix have a higher level of skill mix of qualified staff. Besides regulative factors, normative and market factors influence social services staffing in nursing homes.

### NURSING HOME ADMINISTRATORS' PERCEPTIONS OF PSYCHOSOCIAL CARE IN NURSING HOMES: REPORT ON A NATIONAL SURVEY

C. Galambos[1], K. Simons[3], M. Bern-Klug[2], D. Parker-Oliver[1], N. Castle[4], *1. School of Social Work, University of Missouri, Columbia, Missouri, 2. University of Iowa, Iowa City, Iowa, 3. Baycrest, Toronto, Ontario, Canada, 4. University of Pittsburg, Pittsburg, Pennsylvania*

In 2003, an Office of the Inspector General's report indicated there are gaps in the delivery of psychosocial care in Medicare supported facilities including inadequate care plans and, sometimes, no psychosocial care. In response, a study was conducted to determine nursing home administrators' perceptions about psychosocial care and who delivers such care. This session discusses the results of a national survey of nursing home administrators who responded to a 2005 nursing home turnover study. Participants were asked to describe factors related to the provision of social services and psychosocial care such as type of coverage, social service personnel credentials, social work involvement in care, job functions, reporting structure, and impact on resident quality of care and quality of life. These factors were compared with selected facility characteristics reported in the OSCAR database. Results of the survey will be reported as well as recommendations to enhance psychosocial care within nursing homes.

### SKILLED NURSING FACILITY ADMINISTRATORS' VALUES AND PERCEPTIONS OF SOCIAL WORK SERVICES IN ARIZONA

K.A. Bailey[1], P. Hector[2], R.P. Bonifas[2], *1. Social Work, Bridgewater State College, Bridgewater, Massachusetts, 2. Arizona State University, Phoenix, Arizona*

This presentation reviews results of a survey of skilled nursing facility (SNF) administrators in Arizona regarding the roles, responsibilities, and professional credentials of social workers employed in their facilities. Recruitment efforts and training opportunities were also a focus of inquiry. A team of university and community stakeholders designed the survey, which included 28 items encompassing both demographic characteristics and open-ended questions eliciting administrators' impressions of diverse aspects of social work practice. Results indicate that administrators highly value social workers as members of the interdisciplinary team and these professionals play significant roles in care and treatment planning, discharge planning, and alleged abuse investigations. In addition, they often are involved in marketing and admission duties, experience challenges in managing documentation requirements, and could benefit from more structured training programs. After attending this session, participants will be able to characterize Arizona facility administrators' impressions of SNF social workers and their scope of practice.

### EXPLAINING VARIATION IN JOB SATISFACTION AMONG NH SOCIAL WORKERS

M. Bern-Klug, J. Liu, *Social Work, University of Iowa, Iowa City, Iowa*

We applied Borzaga and Tortia's (2006) conceptual framework of job satisfaction to data representing a nationally representative sample of nursing home (NH) social service directors (n =1,071). The B & T model includes two sets of independent variables: those related to the employee's personal motivations and goals, and a second set related to what the organization has to offer. For this study, we focused on the latter and were able to explain 30% of the variation in "thriving" (we did not have a measure for satisfaction per se) among social service directors. Factors positively related to thriving include: sense of job autonomy, support from boss, and staffing issues. Variables related to characteristics of the employee or the NH did not improve the model.

### WORKFORCE COMPARISONS: LICENSED SOCIAL WORKERS IN NURSING HOMES AND OTHER GERONTOLOGICAL SETTINGS

R.P. Bonifas[1], K. Simons[2], D. Gammonley[3], *1. Social work, Arizona State University, Phoenix, Arizona, 2. Baycrest, KLARU, Toronto, Ontario, Canada, 3. University of Central Florida, Orlanda, Florida*

Individuals residing in nursing homes have complex psychosocial needs; the availability of social workers prepared to address issues specific to this population is a critical component in quality care. This presentation reviews research findings on the context of service delivery for a skilled group of nursing home practitioners: licensed social workers. Using data from the 2004 NASW Workforce Study, comparisons were made between social workers in nursing homes and those in other gerontological settings regarding professional characteristics, work environment characteristics, service delivery patterns, and workforce issues. Results indicate that nursing home practitioners have larger caseloads and serve clients who are more physically and cognitively impaired. They also spend more time on assessment and treatment planning, but report feeling less skilled in providing these services relative to other clinicians. After attending this session, participants will be able to describe differences between nursing home and other types of gerontological social work practice.

## SESSION 50 (SYMPOSIUM)

### STRESS, AGING AND DISEASE

Chair: *G.J. Lithgow, Buck Institute for Age Research, Novato, California*

Aging is often thought to be a failure of homeostasis. Consequently the ways in which humans and other animals respond to environmental change is very important for aging outcomes. Great progress is being made in understanding the relationship between stress responses and lifespan determination. This is also beginning to reveal the underlying reasons that aging is a risk factor for neurological disease. This session shall explore these issues. Speakers: Richard Morimoto, Northwestern University Gary Fisher, University of Michigan

## SESSION 55 (SYMPOSIUM)

### AGE-RELATED DIFFERENCES AND SIMILARITIES IN LEARNING AND MEMORY

Chair: *K. Nashiro, Gerontology, University of Southern California, Los Angeles, California*

We often make decisions based on previous experiences — in order to maximize future gains and minimize potential losses. Previous research suggests that reward-based learning and decision-making abilities decline with age. This is consistent with some neuroimaging evidence showing that older adults have structural and functional declines in reward and learning systems. However, more recent research suggests that some aspects of reward-based learning remains intact in old age, while others decline due to age-related cognitive changes. In this symposium, we will present behavioral and neuroimaging evidence showing age-similarities and differences in various aspects of learning, such as phases of learning (anticipatory, acquisition, feedback phases), types of rewards given upon successful learning (affective or non-affective rewards), types of instructions given (attending or suppressing stimuli), and subsequent memory performance for learned items. Furthermore, we will discuss how positive and negative emotional content affects learning and memory in younger and older adults.

### REINFORCEMENT LEARNING AND AGE-RELATED CHANGES IN RELATIVE CODING IN MESOLIMBIC BRAIN REGIONS

G.R. Samanez-Larkin[1], D.A. Worthy[2], S.M. McClure[1], B. Knutson[1], *1. Psychology, Stanford University, Stanford, California, 2. University of Texas Austin, Austin, Texas*

Emerging evidence from decision neuroscience suggests that although younger and older adults show similar mesolimbic representation of the discrete values of reward outcomes, older adults in some situations show deficits in feedback-driven probabilistic reinforcement learning. In the present study, we sought to further clarify the potential mechanism underlying age-related changes in probabilistic reward learning. Forty adults between the ages of 20 and 85 played a probabilistic reward learning task while undergoing functional brain imaging. A reinforcement learning model was used to assess learning rates and to generate estimates of relative value coding for brain imaging analyses. We found no evidence for an age-related change in the absolute representation of reward outcomes. However, we did observe age-related declines in behavioral learning rates and in the neural representation of prediction errors and expected value suggesting that learning impairments may be due to age-related changes in relative coding in mesolimbic regions.

### POSITIVE EMOTIONAL CONTENT HELPS OLDER ADULTS LEARN MORE EFFECTIVELY

K. Nashiro, M. Mather, *Gerontology, University of Southern California, Los Angeles, California*

An age-related positivity effect has been observed in attention and memory (Mather & Carstensen, 2005). However, how this positivity effect can be harnessed to enhance learning has not been well investigated. To test this possibility, we examined differences between younger and older adults in the rate of learning using a reversal-learning paradigm. In the positive conditions of our two experiments, participants viewed two people concealing their emotions and had to select the person who would smile. Across the two experiments, we tested conditions in which the change that needed to be tracked was an angry facial expression as well as conditions with different types of non-affective outcomes. Older adults performed about as well as younger adults in the positive conditions but performed worse in the negative conditions. Overall, our findings suggest that positive emotional content helps older adults learn more effectively, whereas negative content impairs their learning.

### REWARD ANTICIPATION ENHANCES NEW LEARNING OF REWARD-IRRELEVANT INFORMATION FOR BOTH OLDER AND YOUNGER ADULTS

M. Mather, A. Schoeke, *Davis School of Gerontology, University of Southern California, Los Angeles, California*

We examined whether older adults' new learning could benefit from activation of dopaminergic neural pathways during reward anticipation. Participants played a game in which they had to press a button as soon as they saw a target. Gain trials began with a cue that they would win $.25 if they pressed the button fast enough, loss trials began with a cue that they would avoid losing $.25 if they pressed the button fast enough, and no-outcome trials began with a cue indicating no monetary outcome. The target was a different photo object on each trial (e.g., balloon, dolphin). Among both younger and older adults, recognition memory was best for target objects from gain trials, intermediate for those from no-outcome trials, and worst for those from loss trials. These findings indicate that neural systems involved in reward modulate memory and that these reward-memory system interactions remain intact in older age.

### MEMORY SUPPRESSION OF NEUTRAL AND EMOTIONAL ITEMS IN YOUNG AND OLDER ADULTS

B. Murray[1], K. Muscatell[2], E. Kensinger[1], *1. Boston College, Chestnut Hill, Massachusetts, 2. University of California Los Angeles, Los Angeles, California*

Recent studies have demonstrated that young adults can voluntarily suppress information from memory when directed to. However, it is unknown if this ability persists into older adulthood, or how the emotional content of the information affects the suppression process. Here, data are presented from two studies showing that older and young adults can suppress information from memory when directed to, and this result is not affected by the emotionality of the to-be-suppressed information. Study 1 employed a "think/no-think" task (Anderson & Green, 2001) and showed that older and younger adults exhibited lower recall for words in a "no-think" condition than a "think" condition. Study 2 demonstrated that both age groups could also suppress memory for either positive or negative words. These results suggest that the ability to suppress information is preserved into older adulthood, and there do not appear to be age-related changes in the suppression of valenced information.

## SESSION 60 (PAPER)

## DEMENTIA CAREGIVING

### AN EXAMINATION OF QUALITY OF CARE AS A MECHANISM UNDERLYING CAREGIVER DESIRE TO INSTITUTIONALIZE

D.W. Durkin[1], F. Sun[2], G. Harris[1], M.M. Hilgeman[1], R.S. Allen[1], J.E. Gaugler[4], L. Burgio[3], *1. University of Alabama Center for Mental Health and Aging, Tuscaloosa, Alabama, 2. Arizona State University, Phoenix, Arizona, 3. University of Michigan Institute of Gerontology, Ann Arbor, Michigan, 4. University of Minnesota, Minneapolis, Minnesota*

The decision to place an older adult with dementia in a nursing home or other long-term care facility is rarely sudden, and both premature and late placement have been linked to adverse outcomes for the caregiver (CG) and care recipient (CR). Although previous studies using the Desire to Institutionalize Scale (DTI; Morycz, 1985) have found both CR (i.e. behavior problems) and CG (i.e. burden) variables predict DTI, the quality of care (QOC) provided to the CR has not been examined. Using secondary data from the NIH-funded Resources for Enhancing Alzheimer's Caregiver Health (REACH) II study (N = 613), we examined the relation between caregiver subjective appraisal (Daily Care Bother, Burden, and Behavioral Bother), QOC (Exemplary Caregiving and Potential for Harm), and DTI. Specifically, QOC was examined as a possible mediator of the effects of caregiver subjective appraisal on DTI. Using a SPSS macro developed by Preacher and Hayes (2008) that allows for multiple mediators, we tested the indirect effect of QOC on the relation between CG subjective appraisal and DTI. Results revealed that both Exemplary Caregiving (EC) and Potential for Harm (PFH) partially mediate the relation between the subjective appraisal variables and DTI when examined independently; however, when both EC and PFH are entered as mediators in the same model, the indirect effect of EC is no longer significant. Results suggest that QOC may play a key role in the CG's consideration of long-term care placement, especially the potential for harm.

### CARING FOR MID-TO-LATE STAGE DEMENTIA PATIENTS: A LOVE INTERVENTION FOR CAREGIVERS

J. D'Ambrosio, A.C. Faul, *Kent School of Social Work, University of Louisville, Louisville, Kentucky*

Caregivers of dementia patients carry a heavy burden and report increased strain, depression and decreased mental health. Despite this heavy burden, caregivers know that their relatives with dementia have a human right to be treated with dignity and respect, despite their cognitive state. It is a moral challenge for any caregiver to keep loving a person even after he/she has drastically changed in appearance and cognition. Pitirim Sorokin, a noted sociologist who devoted a whole treatise to the subject of love, developed a theory of love that can effectively be used to guide caregivers through the burden or caregiving while remaining true to the moral task of enhancing the life of the person with dementia. In this presentation we discuss the procedures followed to develop and pilot test a love intervention for caregivers with ten family caregivers of people with mid-to late stage dementia, using the principles of Intervention Design and Development. This intervention guides caregivers through a self-evaluation of five constructs that make up love, while delivering care. Data demonstrates how this self-evaluation, through the lens of Sorokin's love theory, helped caregivers to show less caregiver burden and overall better mental health when they mastered the adequate application of this theory. Qualitative data was gathered throughout the pilot intervention and single subject AB designs were used to track caregiver burden and mental health. Results indicated a much better appreciation of themselves as caregivers, better self-worth and overall less caregiver burden and improved mental health.

### ADULT CHILDREN AND PARENTS WITH DEMENTIA IN ASSISTED LIVING: VISITING, PERCEPTIONS OF CARE, AND PROBLEM BEHAVIORS

D.M. La Fazia[1], L. Teri[1], K.C. Pike[1], N. Hooyman[2], G. McKenzie[3], J. van Leynseele[1], S.M. McCurry[1], *1. Psychosocial and Community Health, University of Washington, Seattle, Washington, 2. University of Washington, Seattle, Washington, 3. Oregon Health Sciences University, Portland, Oregon*

Assisted-living (AL) is the fastest growing residential care option for older adults. Adult children often provide care to a parent even after a move to AL. This study examines the relationship between adult child caregivers' perceptions of care and contact with their parent residing in AL, parent behavioral problems, and staff reaction to these behavioral problems. Data were collected as part of the Staff Training in Assisted-living Residences (STAR) studies to train staff a behavioral problem solving approach to reduce depression and anxiety in residents with dementia. Data were collected on 96 adult children/parents/staff triads. Descriptive statistics, correlational and multiple regression analyses were conducted. Results indicated that adult children were in contact with their AL residing parents, with 91% visiting at least monthly. Adult children had positive perceptions of the care their parents received (M=5.01, SD=.92, Range=2.24-6.92), with staff having caring interactions and being patient with their relative among the highest scored items. More frequent visiting was associated with lower satisfaction with care ($\beta$=-.22, p<.05). Sons visited less in the presence of greater behavioral problems while daughters visited more (β=-.28, p<.06). Greater staff reaction to behavioral problems was a predictor of lower family satisfaction with care (β=-.27, p=.012). These findings indicate the importance of family, resident, and staff interactions for family satisfaction with care.

### CAREGIVER BURDEN, HEALTH UTILITIES AND INSTITUTIONAL SERVICE COSTS IN ALZHEIMER'S DISEASE

E.A. Miller[1], L. Schneider[2], R. Rosenheck[3], *1. Gerontology, University of Massachusetts Boston, Boston, Massachusetts, 2. University of Southern California, Los Angeles, California, 3. Yale University, New Haven, Connecticut*

This study examined the moderating effect of caregiver burden on the relationship between patients' health status and institutional costs in Alzheimer's disease (AD). Data were obtained on 421 community-dwelling patients with AD in the CATIE-AD trial. Outcome variables include hospital, nursing home, residential, and combined institutional costs. Mixed models were employed to estimate the interaction of Health Utility Index (HUI)-III scores (a health status measure) and five measures of caregiver burden. Wherever significant, results indicate that caregiver burden dampens the inverse relationship between health utilities and institutional costs, with the association becoming less negative as burden increases. Altogether 45.0% of the models (9/20) showed this effect (positive coefficient on the burden-HUI interaction term). Interventions should be offered to individuals caring for less advanced AD cases if they experience substantial burden, for even seemingly manageable patients may be at heightened risk for institutionalization if caregivers experience high levels of burden.

### DESIRE TO INSTITUTIONALIZE A RELATIVE WITH DEMENTIA: QUALITY OF PREMORBID RELATIONSHIP AND CAREGIVER GENDER

L. Winter, L.N. Gitlin, *Thomas Jefferson University, Philadelphia, Pennsylvania*

Because most dementia patients live at home and are cared for by family members, considerable research attention has focused on the quality of the caregiver-patient relationship. The quality of this relationship has implications for patient outcomes (e.g., quality of care) and important aspects of the caregiving experience (e.g., burden and deprssive symptoms). We examined its association with the caregiver's desire to institutionalize (DTI), using a sample of 237 caregivers of community-dwelling patients with Alzheimer's disease or related disorders (ADRD). Stronger desire to institutionalize (DTI) was significantly associated with lower quality of premorbid relationship, being female, and the interaction between gender and quality of relationship. The interaction reflected a significant association between relationship quality and DTI for male but not female caregivers. Findings suggest that quality of caregiver-patient relationship may affect whether or how soon the patient is placed in a long-term care facility, especially for male caregivers.

## SESSION 65 (PAPER)

## DEVELOPMENT OF DISABILITIES

### EFFECTS OF RACE AND EDUCATION ON PROGRESSIVE DISABILITY PACING

K. Latham, G. Pavela, *University of Florida, Gainesville, Florida*

Progressive disability is characterized by the gradual onset of disability typically caused by degenerative diseases such as arthritis. It is often defined as having mild impairment prior to disability onset. The pacing of progressive disability is essential to understand, because onset of severe disability signifies loss of independence, often followed by lower quality of life measures and increasing healthcare expenditures. The purpose of this research is to examine the effects of race and education on the pacing of progressive disability. We hypothesize that both being in a minority group or having lower educational attainment will be associated with an accelerated rate of progressive disability onset. Using the first eight waves of the Health and Retirement Study (HRS), we conduct a discrete time event history analysis within a multilevel framework to describe the pacing of progressive disability. Along with the key independent variables of race and education, we also included age and a number of other health measures as controls. Results suggest that race and education influence the pacing of progressive disability. Future research should examine interventions that may slow the onset of progressive disability and thus prolong independence to the fullest extent possible for the entire aging population.

### IDENTIFYING THE RISK FACTORS OF FALLS FOR OLDER ADULTS WHO RECEIVE HOME-CARE SERVICES IN OHIO, USA: LOGISTIC REGRESSION TREE ANALYSIS

T. Yamashita[1,2], D.A. Noe[1], A. Bailer[1,2], S. Mehdizadeh[1,2], I.M. Nelson[2], *1. Miami University, Oxford, Ohio, 2. Scripps Gerontology Center, Oxford, Ohio*

Falling, a major public health problem in the U.S., puts older adults at risk of severe injuries including hip fracture which is associated with increased medical and long-term care expenditures. Additionally, fall-related injuries often result in loss of independence and lower quality of life. Preventing falls is particularly important for vulnerable, community-dwelling older adults who have higher chance of institutionalization compared to healthy adults. However, vulnerable older adults receiving home care service are understudied for fall risk factors. This study identified fall risk factors for participants of Ohio's Medicaid waiver home care services (PASSPORT) program. Logistic regression tree method was used to partition participants into subgroups based on demographic, medical condition, health status, functional limitation and current intervention factors with similar characteristics (e.g., female diabetes patients) and fit a different logistic regression to each subgroup. The results are visualized in an easily interpreted tree-structured chart. The group of participants with incontinence and joint pain, and the group of those with more than 7 different medications, more than 2 ADL limitations (e.g., eating, dressing), age over 78 years and joint pain had the highest risks of falls. Among those at-risk groups, number of medications had positive associations with the chance of falling in a different way for those with joint pain (beta = 0.04) versus those without (beta = 0.07). In accordance with theoretical explanations about the identified risk factors, the application of the logistic regression tree method in the context of fall research and practical implications are evaluated.

### INSUFFICIENT PERSONAL ASSISTANCE FOR ADL DISABILITY AND RISK FOR HOSPITALIZATION AMONG COMMUNITY-LIVING OLDER ADULTS

L.P. Sands[1], H. Xu[2], K. Covinsky[3], *1. School of Nursing, Purdue University, West Lafayette, Indiana, 2. Mississippi State University, Mississippi State, Mississippi, 3. University of California, San Francisco, San Francisco, California*

BACKGROUND. Approximately 20% of older adults with disability in one or more basic activities of daily living (ADL) report they do not have sufficient personal assistance for their ADL disabilities. Self-reported consequences of insufficient ADL assistance include falls, dehydration and skin breakdown. We determined whether self-reports of insufficient personal help were prognostic of hospital admissions. METHODS. 5,992 community respondents to the 1994, 1999, and 2004 National Long Term Care Survey were asked whether in the past week they could have used more personal assistance for the ADL's for which they were disabled. Hospitalizations in the 12 months after each survey were determined from Medicare claims. An extension of the Cox proportional hazards model that accommodates recurrent events was computed to determine the association between insufficient ADL assistance and hospitalizations. RESULTS. Eighty percent of respondents were 75 or older; 72% were female, 87% were white, and 40% lived alone. Unadjusted rates of hospital admission for those with sufficient ADL help were 0.52, 0.62 and 0.78 respectively for those with 1, 2-3 and 3+ ADL dependencies, whereas rates among those who reported insufficient ADL help were 0.81, 0.79, and 0.81 respectively for those with 1, 2-3 and 3+ ADL dependencies. After adjustment for demographics and illness status, insufficient ADL assistance was associated with an increased risk for hospitalization among respondents with 1 ADL dependency (HR = 1.40, 95% CI: 1.07-1.83). CONCLUSION. Programs that provide personal ADL assistance to only the most severely disabled elders may be missing an opportunity to prevent hospitalization.

### ASSESSING THE RISK OF COMPLEX IADL FROM THE PERSPECTIVE OF MEDICALLY-AT-RISK OLDER ADULTS AND THEIR CAREGIVERS

A. Dickerson, J. Gaudy, T. Reistetter, *Occupational Therapy, East Carolina University, Greenville, North Carolina*

The purpose of the descriptive study was to understand the impact of chronic disease on the functional ability of older adults by determining which instrumental activities of daily living are most meaningful and may pose a safety hazard for the medically-at-risk older adult who plans to live independently. Data was collected through individual interviews with twenty older adults and their respective caregivers. The older adults were recently discharged from a hospital due to one of the following medical conditions: heart disease, stroke, COPD, dementia, or diabetes, all chronic conditions that put older adults at risk for safe independent living. Mean age of the older adult participants was 71 years. Results indicated the most important tasks were driving, managing medication, managing finances and phone use with no significant difference between the two groups (older adults and caregivers) in terms of meaningfulness (p<.40). The older adults reported that all tasks were affected by their respective condition. Paired sample t-test to examine difference between the participant's perception of previous level of function and current level of function showed a significant difference all eleven IADLs. The same was true for the caregiver's perception. However, when analysis examined differences between the participant and their caregiver for previous level of function showed a significant difference for shopping for groceries (t=5.62, p<.03), managing medication (t= 4.66, p<.04), and planning a meal (t= 6.52, p<.02). Qualitative results revealed safety issues with medication management and driving. Discussion will focus on the implications of these findings and needed future research.

## SESSION 70 (PAPER)

## HEALTH PROMOTION AND HEALTH LITERACY

### ACTIVE AGING AND EMERGENCY PREPAREDNESS: CAN THE MERGER BE ACHIEVED THROUGH A COMMUNITY DEVELOPMENT INTERVENTION?

G. Gutman[1], M. Kloseck[2], M. Gibson[3], L. Cox[2], *1. Simon Fraser University, Vancouver, Ontario, Canada, 2. The University of Western Ontario, London, Ontario, Canada, 3. St. Joseph's Health Care, London, Ontario, Canada*

The World Health Organization (2008) has endorsed the Active Aging Framework as a platform for promoting health, security and participation of older persons in emergency situations. This 3-phase project combines an Active Aging perspective with a community development approach to prepare residents of a naturally occurring retirement community (NORC) in London, Ontario to cope with naturally occurring and man-made emergency and disaster situations. Purpose: In Phase 1 we reviewed emergency planning guidelines to determine whether they consider the unique needs of seniors. In Phase 2, the focus of this presentation, we aimed to understand NORC residents' perceptions of their needs and their potential sources of support in emergency situations. Method: 7 focus groups were conducted in which participants, provided with a realistic emergency scenario (3 day power loss following an ice storm), considered their own needs/resources, and their neighbours, both for sheltering in place and evacuation. Results: Participants (6 males, 27 females; mean age 79.8; 94% living alone and 42% using a mobility aid), expressed the following concerns: maneuvering stairs, having a sufficient supply of medications, being aware of/able to remember emergency procedures and plans, and lack of concrete and consistent information concerning what to do in an emergency. Discussion: The concerns expressed highlight important issues for emergency planners to address in their messaging to seniors and illustrate the value of a combined Active Aging/Community Development model as a way of engaging seniors in knowledge translation and transfer around emergency preparedness.

### A RANDOMIZED CONTROLLED TRIAL OF A HEALTH PROMOTION INTERVENTION FOR WOMEN AGING WITH DISABILITIES

S. Robinson-Whelen[1], R.B. Hughes[2], N. Elsayegh[1], M.A. Nosek[1], *1. Center for Research on Women with Disabilities, Baylor College of Medicine, Houston, Texas, 2. University of Montana, Missoula, Montana*

Women with disabilities are at risk for an array of secondary health conditions that may be preventable or mutable with improved health behaviors. The authors conducted a randomized, controlled study of a health promotion intervention for women aging with physical disabilities at sites across the country. The 8 week, peer-led, interactive group program covered various health topics and included weekly action planning. Middle-age and older women (N=278) representing a wide range of physical disabilities were randomized to a group program or a wait-list control group. All participants completed measures of health behavior, health, self-efficacy, and social support at baseline, 2 months, 6 months and 12 months follow-up. Data were analyzed using a multilevel growth curve model with three groups: controls, low attendees (<4 sessions attended), and moderate to high attendees (4+ sessions). Health behavior was significantly better at the 6 month follow-up among the mod-high attendees than the two other groups combined. Examining change over time, the mod-high attendees showed improved health behaviors through the 6 month follow-up whereas both other groups declined. Between the 6 and 12 month follow-ups, low attendees leveled off, controls began to increase, and mod-high attendees declined. On several measures, including health-related quality of life and social support, differences between the low and mod-high attendees were larger than differences between the mod-high attendees and the control group. Possible explanations for the low attendees' poorer and declining performance on a variety of measures are discussed as well as strategies to intervene with this group.

### AN INTERNATIONAL COMPARISON OF H1N1 WEB SITES: READABILITY AND USEABILITY FOR OLDER ADULTS

N. Pearce, S. Gardhouse, *University of Waterloo, Waterloo, Ontario, Canada*

Introduction: The Internet has become an important resource for older adults seeking health information. However, nearly one-half of older Americans have low reading skills and almost 80% of older adult Canadians have literacy levels rated at the two lowest IALS levels. Many are also coping with age and disease related changes that limit their use of the Internet. Reading levels and web design factors such as fonts, colors, and navigation may pose barriers to older adults searching for H1N1 information on the Web. Objectives: To evaluate H1N1 websites produced by either national public health agencies or state health departments across 5 international jurisdictions (Australia, Canada, New Zealand, United Kingdom, United States) for readability levels and ease of use by older adults. Methods: The top public health/government H1N1 websites returned across three top-rated search engines (Google, Bing and Yahoo!) were selected for analysis. Readability was assessed using the Simple Measure of Gobbledygook (SMOG), Flesch-Kincaid (FK), and Flesch Reading Ease (FRE). Usability was assessed using The National Institute on Aging Web "senior-friendly" guidelines. Results: Mean readability of web pages was Grade 14.24 using SMOG (range 12.60 – 15.70) and Grade 11.55 using FK (range 9.82 – 23.90). Mean FRE was 48.57 (difficult to read). Mean usability score was 28.67 out of 50 (range 23 -38). Conclusion: The web pages examined required high level reading skills and demonstrated limited usability making these pages unsuitable for many older adults.

### RELATION OF EDUCATIONAL LEVEL, INTERNALITY, AND HEALTH STATUS TO OLDER ADULTS' SELF HEALTH CARE

V.G. Cicirelli, *Psychological Sciences, Purdue University, West Lafayette, Indiana*

Self health care is becoming more relevant to elders' positive health outcomes in view of likely future limitations in formal medical care. The present study examined factors related to the aspect of self health care: seeking information about one's health conditions. Structural equation modeling was used to determine relationships in a hypothesized path model, in which educational level, health status, and internal health locus of control are directly related to seeking health information, while education is indirectly related through health and internality. Participants were 109 Midwestern elders (64% women, 56% married) aged 61-99 (M = 77.1), from a senior center and an independent living residence, interviewed individually. Measures were seeking health information (7-item scale), educational level (7-point scale), health status (4-point self rating), and the internality subscale from Walton's health locus of control scales. Lisrel 8 yielded estimates of the path coefficients in the hypothesized model, with satisfactory goodness of fit (Chi-square for independence = 63.5; RMR = .05; GFI = .98). Path coefficients for variables directly related to seeking information were .28 for education, .27 for internality, and -.01 for health (explained variance = .16). The indirect effect of education was .02. Results confirmed the importance of educational level as well as the equally important factor of internal health locus of control in seeking health information for self health care, with internality and health status as mediating factors.

### PROMOTING COLON CANCER SCREENING AMONG OLDER CHINESE ADULTS: REACHING OUT THROUGH COMMUNITY ELDERLY CENTRES

V. Lou[1,3], K. Tsoi[2], M.C. Wong[2], S.S. Ng[2], S. Choi[2], S. Griffiths[2], J. Sung[2], *1. Social Work & Social Administration, The University of Hong Kong, Hong Kong, Hong Kong, 2. The Chinese University of Hong Kong, Hong Kong, Hong Kong, 3. Sau Po Centre on Ageing, The University of Hong Kong, Hong Kong, Hong Kong*

Background: In 2006, Hong Kong launched a five-year pilot project on bowel cancer education, promotion, and screening that targeted symptomatic adults ages fifty to seventy who were offered a Faecal Immunochemical Test (FIT). Under this project, this program reached out to soon-to-be aged and young-old through Community Elderly Centres (CECs). During a 12 month period, more than two thousand people attended health talks, and about four hundred eligible participants used the FIT screening. Aims: This paper examines the strategy of using CECs as conduits to promote colon cancer screening among older Chinese. Method: Qualitative methods, including focus groups and in-depth interviews, were administered to three groups of stakeholders, including social workers, participants with negative FIT screening results, and participants with positive FIT screening results (4 in-depth interviews). The processes followed semi-structured guidelines and were audio-recorded and transcribed. Successive approximation was used as a method for data analysis. Results: The strategies to used CECs as conduits to reach the elderly were seemingly effective, which is supported by the following four emerging themes: 1) The health promotion matches the service directions of CECs; 2) A rippling effect can be achieved by using the first batch of participants as role models for others; 3) CECs can recruit hard-to-reach older adults; and 4) Social workers could also play support roles by helping participants with their worries and emotional reactions during the process. Conclusion: Reaching older adults through CECs to promote colon cancer screening among older Chinese adults is promising. Policy implications are discussed.

# SESSION 75 (PAPER)

## LIFE GOALS: SELECTION AND REINVESTMENT

### THE PROCESS OF SELECTIVE OPTIMIZATION WITH COMPENSATION IN LEISURE ACTIVITIES AMONG ADULTS WITH ARTHRITIS

M.C. Janke[1], J.J. Jones[2], J. Son[2], L.L. Payne[2], *1. School of Aging Studies, University of South Florida, Tampa, Florida, 2. University of Illinois at Urbana-Champaign, Champaign, Illinois*

Research suggests that adults use the process of selective optimization with compensation (SOC) in their leisure activities to promote successful aging when faced with changes in physical abilities. Individuals with arthritis report ceasing their participation in valued activities (i.e., leisure) as a result of their arthritis which has been associated with increased depressive symptoms (Katz & Yellin, 2001). This study examines the SOC strategies adults use in their leisure as a means of coping with their arthritis and is drawn from a larger study on leisure and arthritis. Qualitative data were obtained from adults who participated in 6 focus group sessions (N = 34) related to their arthritis and leisure. The sample had an average age of 70, was 83% White, 88% female, and 44% "resource-poor". The transcripts were initially coded for statements related to the concepts of elective-based selection (EBS), loss-based selection (LBS), optimization (OPT), and compensation (COMP) by three independent researchers. A codebook of themes was then developed using these codes and the descriptions of these processes as outlined by Freund and Baltes (2002). Using content analysis, the data was then independently reanalyzed for these themes by two members of the research team. We found evidence of all four SOC processes in relation to leisure participation. Additionally, we found that most individuals in our sample ceased an important leisure activity due to their arthritis symptoms. We will discuss these findings in terms of implications for helping adults with arthritis self-regulate and adapt their leisure to promote successful aging.

### DOWNSIZING LIVES, DOWNSIZING STORIES: PATTERNS OF REINVESTMENT AND OPTIMIZATION IN LATER LIFE

M.R. Luborsky, C. Lysack, K. Cross, J. Van Nuil, *Institute of Gerontology, Wayne State University, Detroit, Michigan*

PROBLEM. Older adults face a daunting task: while they continue to experience multiple relationships (present and remembered), investment in their own and other's futures, and shifting life interests and capacities, they also confront tasks to reconfigure the place where their social life and objects are housed. Gerontological knowledge about aging in place and preserving physical and psychosocial independence is not matched by insights into how older adults contemplate and undertake processes of downsizing moves and possessions. APPROACH. This paper describes the ways selective optimization with compensation (SOC; Baltes & Baltes, 1990) infuses downsizing of possessions and homes. Competing hypotheses are examined regarding the interpretation of outcomes of material changes in lives to identify patterns of social and psychological reinvestment and optimization. DESIGN. We reported results from a study designed to specify both the features of the downsizing process and the narrative structures for representing downsizing. Data include narratives and semi-structured interviews from 40 older men and women who recently downsized their possessions and moved to smaller residences drawn from an ongoing study of downsizing and household moves in Michigan and Kansas. FINDINGS from narrative and content analyses indicate downsizing dynamics feature:

(a) value dilemmas at multiple levels (independence; psychosocial development, family development, societal norms); (b) mixed loyalties (self, family, community), (c) unexpected positive investment and opportunities for growth (vs. loss); and, (d) and key story types, and age-specific styles. DISCUSSION considers later life story telling and the intersection of telling, living and negotiating social transitions. [NIH #R01AG030477]

### LIFE INVESTMENT AND PSYCHO-PHYSICAL WELL-BEING IN OLD AGE

A.K. Leist, D. Ferring, *Faculté des Lettres, des Sciences Humaines, des Arts et des Sciences de l'Education, University of Luxembourg, Walferdange, Luxembourg*

According to life investment theory, the importance of life domains and goals shifts across the life span (Staudinger, 1996). Developmental theories explain the adjustment of goals to current life circumstances as an adaptive mechanism to ensure psychological well-being (e.g., Heckhausen & Schulz, 1995; Brandtstädter & Renner, 1990). The present study picks up these notions by, firstly, investigating content and meaning of life investment domains by a qualitative approach and, secondly, by exploring associations of life investment domains and indicators of psycho-physical well-being by quantitative methodology. A total of 62 participants aged 65 to 89 years answered to the question "Who or what is currently very important to you?" Categories were developed using qualitative content analysis, answers were then categorized by independent raters. Inspections of frequency showed that participants mentioned their own psycho-physical well-being and relationships with family and friends as very important goals. Other emerging topics were everyday activities (e.g., going shopping), hobbies, and concrete goals (e.g., going on a vacation). Values like generativity, individual autonomy, continuity, and harmony constituted further categories. Another topic concerned goals judged as irrelevant or unrealizable (e.g., not be able to go to the movies anymore). In addition, answers covered personal worries as well as worries concerning global threats, such as war or poverty. As subsequent quantitative analyses showed, the number and valence of mentioned life investment domains was related to age and measures of psycho-physical well-being.

## SESSION 80 (PAPER)

## VITALITY AND POSITIVE AFFECT

### RELATION BETWEEN AGE, UNDERSTANDING OF EMOTIONS AND PERCEIVED EMOTIONAL INTELLIGENCE

N. Galdona[1], P. Fernandez-Berrocal[2], J. Yanguas[1], E. Orce[1], I. Etxeberria[1], E. Aldaz[1], L. Coello[1], E. Urdaneta[1], *1. Fundacion Instituto Gerontologico Matia INGEMA, Donostia-San Sebastian, Spain, 2. Facultad de Psicologia, Universidad de Malaga, Malaga, Spain*

The ability to interpret emotional cues has been argued to play an important role in maintaining successful relationships and healthy psychological functioning. Being able to identify others emotions from facial expressions or written descriptions is seen as a key component in the concept of emotional intelligence, along with the ability to empathize with others emotions. In the current study, we investigated the relationship between the ability to empathize with others emotions and perceived emotional intelligence among elderly people. Forty eight people (29% men and 71% women) aged beetween 65 and 88 with an average age of 74, participated in this study. Perceived Emotional Intelligence (PEI) was evaluated by the Trait Meta Mood Scale-24. While, the ability to empathize with others emotions was evaluated by the revised version of the Eyes Test. The results of the Eyes Test showed that men scored a mean of 15.3 (SD=3.9), whereas women scored sligthly higher with a mean of 16.4 (SD=4.8). In men a significant relationship was found between Emotional Attention (r=0.67, p<0.01) and Eye test total score only in men. Older adults poor performance on the Eyes task may reflect a specific deficit of aspects of identifying emotional cues from eyes. Changes associated with age predict age-related decline in performance on tests of emotion understanding due to the involvement of particular brain regions that are affected by normal aging. On the other hand, these findings indicated the link between levels of Emotional Attention and the ability to empathize with others emotions.

### A MIXED-METHODS APPROACH TO SYNTHESISING RESILIENCE RESEARCH: DEFINITION, MEASUREMENT AND GAPS IN THE EVIDENCE

G. Windle, *Bangor University, Bangor, Wales, United Kingdom*

This paper summarises some of the findings from the Resilience and Healthy Ageing Network, a multi-disciplinary group of academics and stakeholders convened to explore the role of resilience in achieving healthy ageing across the life-course. The aim of the work programme was to unite and build upon previous work and existing evidence on resilience, and strengthen this with new perspectives and collaborations, thereby enhancing research capacity and development. The work was undertaken through a systematic review of the literature, concept analysis and academic and stakeholder consultation. Knowledge transfer has been embedded in the work processes. The concept analysis found that the complexities of defining what appears to be the relatively simple construct of resilience are widely recognised in research. The data synthesis enabled a clear identification of the antecedents, defining attributes and consequences of resilience. A working definition was developed. Variations and misunderstandings of what resilience actually is can create considerable challenges for trying to measure or assess it. A methodological review identified fourteen resilience measurement scales, and results are discussed in relation to the pros and cons of each measure, and their capacity to reflect the complexity of the concept of resilience. Within a life course framework a range of research gaps were identified, including the lack of evidence from older populations, transitions across all developmental stages, especially from adolescence onwards, robust evaluations of interventions, and multi-level/multi-disciplinary study of resilience, especially examining the interplay between the individual (biological and psychological), the immediate social environment and wider contexts.

### THE IMPORTANCE OF VITALITY IN PROMOTING SELF-RATED HEALTH THROUGHOUT ADULTHOOD AND OLD AGE

R.A. Burns, K. Anstey, K.A. Sargent-Cox, *AGeing Research Unit, Australian National Universiry, Canberra, Australian Capital Territory, Australia*

Perceptions of self-rated health (SRH) typically decline with age and strong associations with physical and functional health are identified. Poor SRH is associated with mortality, stroke, mental health and increased health service utilization. A dearth of information describes the extent positive well-being constructs like vitality impact on SRH. Using the SF-36 vitality and mental health sub-scales, and single SRH item, we tested whether vitality and mental health report comparable effects on SRH in middle adulthood and old age over time. Participants (n = 50 652) were obtained from the DYNOPTA project, a harmonized dataset comprising 9 Australian longitudinal studies. At baseline, participants were aged 45 thru 95 years (M = 60; SD = 11), predominantly female (66%) and followed for up to 10 years. Generalized Estimating Equations identified a decline in SRH over time (OR = .983; 95% CI = .982-.985), whilst baseline vitality (OR = 1.024; 95% CI = 1.024-1.025) was a most important predictor of SRH, not mental health (OR = 1.004; 95%CI = 1.004-1.005). Latent Growth Curve models reported baseline ($\beta = .669$; $p < .001$) and change ($\beta = .627$; $p < .001$) in vitality as significant predictors of change in SRH whilst effects for mental health were negligible. We conclude that vitality, and not mental health, is a more important predictor of change in SRH in old age and emphasize that addressing mental health needs does not appear to be the most important mechanism to limit decline in SRH in old age.

### TODAY I AM GRATEFUL... GRATITUDE, REDEMPTION AND WISDOM

S. Koenig, K. Naschenweng, J. Gluck, *Psychology, University of Klagenfurt, Klagenfurt, Austria*

The current study which precisely explores the linkage between wisdom and gratitude is imbedded in a greater wisdom project, namely “The Development and Manifestation of Wisdom”. Within this project it is proposed that experience with and reflection upon different life events is crucial for the development of wisdom in real life. Therefore in standardized interview sessions autobiographical narratives concerning different live events were collected from wisdom nominees and young and old control participants. For the purposes of the present study, the focus was on how often participants spontaneously mentioned feelings of gratitude within their autobiographical memory narratives. In addition to this narrative approach, participants later completed a self-report measure of trait gratitude (Watkins et al., 2003) and several wisdom-relevant measurements. Furthermore they listed what they feel grateful for in their lives. Overall, the results indicate that feelings of gratitude play an important role in the lives of wisdom nominees. Wiser individuals were more likely to mention spontaneously that they feel grateful for both positive and negative live events, and showed a greater disposition toward gratitude. Furthermore, differences concerning what participants were grateful for in their lives could be identified. Finally relations between the measurements of gratitude and relevant correlates of wisdom were found. The findings suggest that gratitude plays an important role in the manifestation as well as in the development of wisdom. Implications for wisdom research are discussed.

# SESSION 85 (PAPER)

## ACCESS TO CARE: WHAT LARGE DATABASES TELL US

### BLACK-WHITE DISPARITY IN DISABILITY: THE ROLE OF SELECTED HEALTH CONDITIONS

H.E. Whitson[1,2,3], S. Hastings[1,2,3], L.R. Landerman[2], G. Fillenbaum[2], H. Cohen[1,2], K. Johnson[1,2], *1. Internal Medicine, Duke, Durham, North Carolina, 2. Duke Aging Center, Durham, North Carolina, 3. Durham VA Medical Center, Durham, North Carolina*

OBJECTIVE To determine the independent contributions of selected health conditions to the Black-White disparity in disability rates among older Americans DESIGN Cross-sectional analysis of a community-based cohort SETTING Urban and rural areas of central North Carolina PARTICIPANTS 2966 adults participating in the Duke Established Populations for Epidemiologic Studies of the Elderly (EPESE) MEASUREMENTS: Self-reported data on sociodemographic and health variables, short portable mental status questionnaire, basic and instrumental activities of daily living (BADLs and IADLs) RESULTS Fifty-five percent of the cohort was Black. Compared to Whites, Blacks were more likely to report BADL disability (odds ratio [OR] 1.39, 95% confidence interval [CI] 1.15-1,68) and IADL disability (OR 1.49, 95% CI 1.27-1.74). Controlling for demographics and socioeconomic factors, Blacks were more likely to have obesity and diabetes and less likely to report vision problems, history of fracture, and heart attacks. The increased prevalence of obesity and diabetes among Blacks independently accounted for >30% of the Black-White difference in BADL disability. CONCLUSIONS Higher rates of obesity and diabetes in Black older Americans, even after controlling for demographic and socioeconomic variables, are important contributors to racial disparity in disability. On the other hand, the difference in Black-White disability rates is lessened by disabling conditions that are more common in Whites, such as age-related macular degeneration and osteoporosis. Racial disparity may increase in future generations if treatment for these conditions advances without concomitant gains in the prevention and treatment of obesity and diabetes in older Blacks.

### EFFECT OF HOSPITAL OWNERSHIP ON FEEDING TUBE USE AMONG BLACK AND WHITE ADVANCED DEMENTIA PATIENTS

S. Cai[1], P. Gozalo[1], V. Mor[1], S. Mitchell[2], J. Bynum[3], S. Kuo[1], J.M. Teno[1], *1. Brown University, Providence, Rhode Island, 2. Harvard Medical School, Boston, Massachusetts, 3. Dartmouth Medical School, Lebanon, New Hampshire*

Background: Dementia is a terminal disease and eating problems often herald its final stage. Existing evidence suggests that feeding tubes (FT) do not improve patient outcomes. Objective: To determine whether hospital ownership affects the within-hospital difference of FT insertion among black and white nursing home residents (NHR) with advanced dementia. Methods: All hospitalizations of NHR with advanced dementia (CPS>= 4) were identified from matched Minimum Data Set and Medicare claims from 2000-2007. Only hospitals with at least 30 admissions overall and 5 admissions from black NHR were included. Hospitals were stratified by ownership (for-profit, private nonprofit, and church- affiliated nonprofit). Base logit and conditional fixed-effects logit models were estimated for each stratum; hospitals’ FT insertion rate differentials by race were compared across stratum. Results: Between 2000 and 2007, 62,733 NHR with advanced dementia were admitted to 959 hospitals (24% for-profit, 16 % church-affiliated nonprofit). Within a hospital, blacks are more likely to have FT insertion than whites (OR=2.36, 2.12, 1.87 in for-profit, private nonprofit, and church-affiliated nonprofit hospitals, respectively, $P<0.001$), accounting for individual risk-factors, hospital fixed-effects, and time trend. The within-hospital racial disparity is greater in for-profit hospitals than in church-affiliated nonprofit hospitals ($P<0.05$). Across-hospital variations may also contribute to the difference in FT use between black and white NH residents. Conclusion: Black NHR with advanced dementia admitted to hospitals are more likely to have a FT inserted than those who are white; this differential varies by hospital ownership status, suggesting the influence of provider practices.

### A MODEL FOR THE USE OF VETERANS HEALTH AFFAIRS AND/OR INDIAN HEALTH SERVICE BY OLDER AMERICAN INDIAN AND ALASKA NATIVE VETERANS

B. Kramer[1,2], S. Jouldjian[1], M. Wang[1], M. Mitchell[1], B. Finke[3], *1. VA Greater Los Angeles Healthcare System, Los Angeles, California, 2. David Geffen School of Medicine at UCLA, Los Angeles, California, 3. Indian Health Service, Nashville, Tennessee*

Background: One-quarter of American Indian and Alaska Native (AIAN) Veterans who are enrolled in the Indian Health Service (IHS) also receive care at the Veterans Health Administration (VHA). Objective: Understand the relationship between patient and organizational factors in predicting dual use of VHA and IHS. Methods: We developed multilevel models to describe the interplay of patient and organizational factors in a sample of 18,892 AIAN Veterans receiving care at 201 VHA and IHS facilities during FY02 and FY03. Since unique factors related to each organization may perform differently, we created a model for dual use versus VHA-only and a model for dual use versus IHS-only. Results: The common explanatory variable of dual use in both models was the number of unique diagnoses (per patient). Other demographic, medical need and organizational factors differed across models. Medical need and advancing age increased the likelihood of dual use in IHS Model and decreased the likelihood of dual use in VHA Model. In both models, multiple patient factors were related to dual use, while only one measured organizational factor was significant. Conclusions: Patients’ medical needs drive dual use. For AIAN Veterans with the greatest medical needs, VHA is the exclusive provider or shares responsibility with IHS.

### ACCULTURATION AND PROGRESSION OF LATE-LIFE DISABILITY IN OLDER MEXICAN AMERICANS

J. Delgado[1,2], E. Jacobs[1,2], K. Markides[3], C.F. Mendes de Leon[2], *1. John Stroger Jr. Hospital of Cook County, Chicago, Illinois, 2. Rush University Medical Center, Chicago, Illinois, 3. University of Texas Medical Branch, Galveston, Texas*

Late-life disability is an important health condition in older age. Older Hispanics have a higher prevalence of disability than non-Hispanic whites. Acculturation is an important factor in chronic conditions such as obesity and diabetes, however little is known about the effect of acculturation in disability. The aim of the study was to examine the relationship between acculturation and the progression of late-life disability in Mexican Americans. Methods: Data was obtained from the Hispanic Established Populations for the Epidemiological Study of the Elderly (H-EPESE). Interviews were performed in six consecutive waves between 1993 and 2007. Data included measures for disability (ADLs, IADLs, and a summary measure of performance based tests of physical function), acculturation and socioeconomic status (income, education). Longitudinal analysis models were used to examine the association of acculturation with each disability outcome. Results: There were 3050 participants in the study. Higher acculturation was associated with lower ADL disability (coef=-0.1650, p=0.004), lower IADL disability (coef =-0.2030, p<0.001) and higher physical function level (coef=0.3039, p=<0.001) at baseline. Acculturation was not associated with change in either ADL or AIDL disability over time (p=0.40 and p=0.37 respectively). Higher acculturation was associated with less decline in physical function scores over time (coef=0.0239 p=0.03). This longitudinal association remained significant after adjustment for education and income (coef=0.0265, p=0.02). Conclusion: The findings from this longitudinal study suggest that higher acculturation has a protective effect on late-life disability and on the decline of basic physical function in older Hispanics.

## SESSION 90 (SYMPOSIUM)

### TRANSITIONS IN STROKE CARE: FINDINGS FROM THE STROKE TELEMEDICINE ACCESS RECOVERY (STAR) PROJECT

Chair: *P. Gregory, Physical Medicine and Rehabilitation, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*
Discussant: *S.L. Szanton, Johns Hopkins Medical Institutions, Baltimore, Maryland*

Stroke is a devastating disease and a leading cause of disability. While care focuses mainly on the first few hours of the acute hospitalization, stroke is a chronic disease filled with transitions across the continuum of recovery. Effective recovery management through transitions involves an understanding of three key issues: 1) identification and management of risk factors 2) prevention of stroke complications and 3) access to stroke rehabilitation. This symposium will present preliminary results of these key factors in participants of the Stroke Telemedicine Access Recovery (STAR) Project. The STAR Project is a new study designed to maximize access to stroke recovery services in a rural community hospital in the stroke belt. The population is predominately minority and historically minorities have a greater stroke prevalence and severity compared to whites. Evaluation of these key factors in this predominant minority population will provide a better understanding of recovery across the continuum. The "Stroke Risk Factors" paper will characterize the stroke risk factors of the study population and describe how they evolve over the course of the acute hospitalization. The "Prevention of Stroke Complications" paper will evaluate the prevalence of two measures associated with stroke complications prior to and presently at the STAR study hospital. The "Access to Stroke Rehabilitation" paper will compare the access to acute and post acute stroke rehabilitation prior to and currently at the STAR study hospital. A focus on these three key indicators can improve the overall quality of care and ease transitions across the continuum of recovery.

### IDENTIFYING STROKE RISK FACTORS

S.W. Williams, P. Gregory, A.C. Felix, K.R. Faurot, D. Urlaub, P.E. Sweat, *Physical Medicine and Rehabilitation, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

While stroke outcomes are improving, North Carolina residents continue to experience high rates of strokes and poor stroke related outcomes. This paper examines risk factors for a tri-racial population hospitalized with a stroke. We focus on modifiable risk factors (e.g., diabetes, hypertension, cholesterol, smoking history, obesity, and physical activity) rather than non-modifiable (e.g., age, racial minority, and geographic region) factors. Findings show that within this population of White, African American, and American Indian stroke survivors, 47% presented with diabetes, 87% with hypertension, 43% with coronary artery disease, and 37% with hyperlipidemia. In addition, among this mostly female sample (67%), 33% reported a prior stroke and 20% a history of smoking. Given that, in this sample, the modifiable risk factors also increase the risk of a recurrent stroke, secondary prevention through patient and family education is of critical importance.

### PREVENTION OF COMPLICATIONS DURING STROKE HOSPITALIZATION: A PILOT PROJECT

A.C. Felix, *Neurology, University of North Carolina, Chapel Hill, North Carolina*

Life-threatening complications, including pneumonia and deep venous thrombosis (DVT), arise frequently after a stroke. These complications increase morbidity, mortality and prolong the length of hospital stay. Pneumonia can be prevented with a simple bedside screening assessment of swallowing (dysphagia screening). Prior to initiation of Phase I of the STAR project, dysphagia screening was documented in 35 % of patient charts. After the implementation of the Phase I of the STAR Project, documentation of dysphagia screening was 93%. DVT prevention was documented in 45% of patient charts prior to Phase I of the STAR project and 52% after the initiation of the project. While many factors may impact adherence to practice guidelines for hospitalized stroke patients, the STAR project demonstrates that increased awareness of diagnosis, by participation in a research study, may be associated with increased adherence to current practice guidelines for stroke patients.

### ACCESS TO STROKE REHABILITATION IN THE STROKE TELEMEDICINE ACCESS RECOVERY (STAR) PROJECT

P. Gregory, A.C. Felix, S.W. Williams, K.R. Faurot, D. Urlaub, P.E. Sweat, *Physical Medicine and Rehabilitation, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

Stroke is a leading cause of long-term disability. Access to early aggressive rehabilitation maximizes recovery. Geographic disparities impair access to these recovery services. The Stroke Telemedicine Access Recovery (STAR) Project is designed to increase access to stroke rehabilitation by implementing a remote physiatry consultative service to oversee care. We compared the rates of acute and post acute rehabilitation access before and after the start of the STAR Project at a rural community hospital. Rehabilitation assessment overall has increased from 75% to 97%. Physical therapy evaluations increased from 67% to 93% since the start of STAR, occupational therapy assessments increased from 45% to 73%, and Speech therapy assessments increased from 58% to 73%. Results show that early into the study there has been an increase in access to stroke rehabilitation services. Improved access to stroke recovery services will ultimately improve functional outcomes and ease transition across the continuum.

## SESSION 95 (SYMPOSIUM)

### POLICY SERIES SYMPOSIUM: AGE DISCRIMINATION AND EMPLOYMENT ISSUE OF OLDER WORKERS IN GOOD TIMES AND BAD

Chair: *A.A. Sterns, College of Nursing, Kent State University, Kent, Ohio, University of Maryland, Adelphia, Maryland, Creative Action LLC, Akron, Ohio*

The national unemployment figures have risen to over 10%, with the underemployed reaching to over 17%. About 2 million people aged 55 and over were unemployed in January 2010, bringing the unemployment rate for this age group down to 6.8 percent from 7.2 percent in December, 2009. These represent unemployment rates not seen since the late 1940s (Rix, 2010). More than 1.4 million older persons reported that they would like to be working but were not in the labor force, that is, they were neither working nor looking for work. Nearly one-quarter of a million were discouraged workers; they were not looking for work because they believed that no work was available, employers would find them too old, they lacked the necessary schooling or training, or that they faced other types of discrimination (Rix, 2010). Utilizing current legislation of the ADA and the ADEA can assist the re-entry into the workforce for adults after disability. Harvey Sterns and Anthony Sterns will review the current interpretation of the ADA and ADEA legislation and how that is being implemented by organizations. Sarah Rix will discuss the growing number of EEOC filings for age discrimination and look at the trends of employment and unemployment as the economy has grown and declined. Krystal Culler and H. Sterns will look at the impact of disability on employment and provide recommendations for utilizing the ADA and ADEA legislation to support return to work after disability. This symposium is sponsored by the Aging and Work Taskforce.

### AGE DISCRIMINATION IN EMPLOYMENT-DOES GERONTOLOGICAL RESEARCH INFLUENCE COURT DECISIONS

A.A. Sterns[1,2,3], H.L. Sterns[4], *1. College of Nursing, Kent State University, Kent, Ohio, 2. University of Maryland, University College, Adelphia, Ohio, 3. Creative Action LLC, Akron, Ohio, 4. The University of Akron, Akron, Ohio*

In general, the industrial psychological literature for many years has not supported a link between age and job performance (McEvoy & Cascio,1989; Ng, T. W. H., & Feldman, D. C. (2008).Rhodes, 1983; Sterns & McDaniel, 1994; Waldman & Avolio, 1986). Plaintiffs may try to show that there are ways to either compensate for any declines or argue the employer should test for declining ability or performance (EEOC v. City of Minneapolis, 1982; EEOC v. City of St. Paul, 1982). If it is possible to show the link between ability and performance, then it should also be possible to develop valid tests of those abilities and test for the requisite abilities. This paper will review current court decisions that have supported older worker abilities and the opportunity to continue work.

### AGE DISCRIMINATION IN EMPLOYMENT—MORE OF A ROLE FOR PUBLIC POLICY?

S.E. Rix, *AARP, Washington, District of Columbia*

The number of age discrimination charges filed with the EEOC rose sharply over the past year, a development likely to continue as job losses among older workers mount. A majority of older workers maintain that, based on what they have seen or experienced, older workers do face age discrimination today. This figure, too, may rise as the recession continues. Yet, the EEOC finds reasonable cause that discrimination has occurred in fewer than 5 percent of the charges; even fewer cases are litigated. This presentation discusses the results of recent AARP research on (1) older workers' perceptions of and experience with age discrimination and (2) the role that age discrimination legislation has played in addressing the needs of discrimination victims. The paper highlights the strengths and weaknesses of current legal protections, possible reforms, and the role workers themselves must play to prevent discriminatory actions and increase the number of "valid" charges.

### THE IMPACT OF ADA AND ADEA ON EMPLOYMENT AFTER LATE LIFE DISABILITY

K.L. Culler, H.L. Sterns, *The University of Akron, Akron, Ohio*

As early as 1995, Sterns and Sterns noted the impact of the Americans with Disabilities Act (ADA) and the Age Discrimination in Employment Act (ADEA) as an emerging issue. Utilizing current legislation of the ADA and the ADEA can assist the re-entry into the workforce for adults after disability. The continuing issue of later life disability and return to work may be even more important today since many individuals need or want to work longer due to needing more financial resources or to engage in meaningful activities (Czaja and Sharrit, 2009). An important part of the care approach should make return to work evaluations fair and supportive for the employee while also being effective for the employer. Future policy should take into consideration that approximately 21.3 million people aged 16-64 had a condition that affected their ability to work (U.S. Census Bureau 2000) and that the ADEA is anticipated to cover over 88 million Americans by 2015 (AARP 2008). Recommendations for utilizing the ADA and ADEA legislation to support return to work after disability will be highlighted in this presentation.

## SESSION 100 (SYMPOSIUM)

### ELDER CARE IN CHINA

Chair: *L. Li, School of Social Work, University of Michigan, Ann Arbor, Michigan*

Discussant: *D. Biegel, Case Western Reserve University, Cleveland, Ohio*

Population aging in the context of rapid social change following the economic reforms has brought issues of elder care to the forefront in China. This symposium will bring together three qualitative studies that examine different aspects of elder care in China. The first paper by Li, Sui & Gao was based on the experience and perspective of 24 older Chinese with chronic illness and impairment. It reports how older Chinese in rural and urban areas were cared for by their families and what older persons perceived as good care. The second paper by Zhan explored issues related to using paid home care "Baomu", which has been increasing in urban China as adult children become less available to care for their elderly parents. Data from four focus groups reveal that using "Baomu" may relieve some burden of adult children yet could create new problems. The final paper by Wu et al. aims to develop behavioral intervention protocols to preserve cognitive health for elders with cognitive impairment in China. Data collected from caregivers of people with MCI and of those with mild/moderate dementia suggest that the caregivers recognized the importance of diet and exercise in maintaining cognitive health and were interested in using either or both to help their care recipients. The discussant, Dr. Biegel, will address common themes in these three papers and draw comparison between the United States and China.

### INFORMAL CARE RECEIVED BY OLDER PERSONS IN CHINA

L. Li[1], Y. Sui[2], L. Gao[3], *1. School of Social Work, University of Michigan, Ann Arbor, Michigan, 2. Renmin University of China, Beijing, China, 3. University of Jinan, Jinan, China*

This study aims to understand the informal care received by older persons in China, and their perception of quality of care. In-depth interviews were conducted with 24 elderly Chinese who had chronic illness and/or impairment. Half of them resided in two urban neighborhoods in Jinan city, Shandong and half lived in two nearby villages. They included 13 men and 11 women who averaged 72 years old. Most lived with their spouse (n=17), six lived alone and one lived with adult children. Four major themes were identified. (1) The whole family system was involved in elder care. (2) Spouse was an invaluable yet vulnerable asset for those married, eldest son was the care-in-charge for the widowed. (3) Rural and urban elders differed in what and how care was received, and the expectation of adult children as care providers. (4) Positive interaction was the defining feature of good care.

### PAYING FOR XIAO AT HOME—HIRED HOME CARE SERVICES AS AN OPTION OF LONG TERM CARE IN CHINA

H.J. Zhan, *Sociology, Georgia State University, Atlanta, Georgia*

This paper uses qualitative data of 4 focus group discussions with elders and family members collected in 2008 -09 in Nanjing China to discuss the issue of paid home care as an option of long term care services in China. Due to the increasing unavailability of adult children in urban China, many families have to hire home-care workers (or "baomu") to be live-in home care providers for elderly parents with disabilities. Major issues related to this practice of "baomu" include: male/female gender mis-match, crowded housing, incompatibility of personalities or habits, and lack of trust. To relieve the pressure of long-term care by adult children, the author argues for a promotion of a neighborhood-based surveillance system for both home care "baomu" practices at home and small scale elder care institutions in the neighborhoods.

### PRESERVING COGNITIVE HEALTH FOR INDIVIDUALS WITH COGNITIVE IMPAIRMENT: VIEWS FROM CAREGIVERS OF PATIENTS WITH MILD COGNITIVE IMPAIRMENT (MCI) AND DEMENTIA IN CHINA

B. Wu[1], H. Wang[2], D. Cui[3], H. Chen[5], Q. Wang[3], Z. Mao[3], S. Levkoff[4], *1. Gerontology, University of North Carolina at Greensboro, Greensboro, North Carolina, 2. Peking University Institute of Mental Health, Beijing, China, 3. Wuhan University School of Public Health, Wuhan, Hubei, China, 4. Brigham and Women's Hospital, Boston, Massachusetts, 5. Havard Medical School, Boston, Massachusetts*

This study aims to develop behavioral intervention protocols to preserve cognitive health for elders with cognitive impairment in China. A sample was drawn from memory clinics in Beijing and Wuhan, China. A total of 49 caregivers were enrolled in the study, including 25 MCI caregivers and 24 caregivers for mild/moderate dementia. We implemented a mixed methods approach to data collection, using a quantitative questionnaire to obtain information on care recipients' past and current health habits and qualitative semi-structured interviews to explore their views on potential behavioral interventions and the implementation of these interventions. Participants addressed the importance of diet and exercise in maintaining cognitive health. MCI caregivers expressed interest in a combined diet and exercise intervention, while dementia caregivers expressed more interest in diet alone, given more physical impairment among care recipients with dementia as compared to those with MCI. This study also discusses the strategies for implementing the interventions.

## SESSION 105 (SYMPOSIUM)

### FOLLOWED TO EXTINCTION: PREDICTORS OF EXCEPTIONAL SURVIVAL IN VERY LONG TERM COHORT STUDIES

Chair: *D. Melzer, Epidemiology and Public Health, University of Exeter, Exeter, United Kingdom*
Co-Chair: *J. Guralnik, National Institute on Aging, Besthesda, Maryland*
Discussant: *B. Willcox, Honolulu Aging Study, Honolulu, Hawaii*

Identifying determinants of healthy aging is of increasing interest in gerontology. Progress has been made by comparing ES to younger controls. However, the comparability of these groups has been questioned, as the younger controls have generally experienced very different material, social and medical care circumstances from those born several decades prior. Data from deceased cohort-matched controls of exceptional survivors is now emerging from long established cohorts, whose participants have been followed until near extinction. In this symposium we discuss emerging results from three such aging cohorts and one novel cohort: the Honolulu Heart Program (HHP), the Framingham Heart Study (FHS), the Iowa EPESE Study, and the Keys to Optimal Cognitive Aging Project (KOCOA). The HHP and FHS were both originally NHLBI cohorts established to study risk factors for cardiovascular diseases. The HHP began in 1965 with 8,006 ethnic Japanese men living in Oahu, Hawaii while the FHS began in 1948 with 2,336 and 2,873 men and women, respectively, from Framingham, Mass. As the cohorts aged, ancillary studies and aging phenotypes were begun, The Established Populations for Epidemiological Study of the Elderly - Iowa site (EPESE) was a US National Institute on Aging cohort study of demographic, medical, social, psychological and lifestyle factors. It included 3674 community dwelling people aged 65 plus first seen in 1981/82. Death certificates for all but 200 were obtained in 2008. The KOCOA project is a novel cohort study of the oldest-old in Okinawa, Japan, focused on predictors of healthy cognitive aging.

### EARLY LIFE PREDICTORS OF EXCEPTIONAL SURVIVAL IN THE IOWA EPESE-STUDY

A. Dutta[1], J. Guralnik[2], R. Wallace[3], D. Melzer[1], *1. Epidemiology and Public Health, University of Exeter, Exeter, United Kingdom, 2. National Institute on Aging, Besthesda, Maryland, 3. University of Iowa, Iowa City, Iowa*

Aim: To identify the early life and study baseline characteristics predicting exceptional survival Methods: Data were from the Iowa EPESE. Exceptional survivors were defined as the 10% longest-lived (men reaching age 94 years plus and women 97 years plus). Our analysis included individuals aged 65 to 85 at baseline who lived at least 3 years. Results: Earlier life factors associated with exceptional survival included smoking status, body mass index at age 50, parent's age of death, but not marital status or educational attainment. At baseline, better health and cognitive status were predictive of exceptional survival. Life satisfaction as a predictor was not independent of health status measures. Earlier birth order amongst siblings was only predictive in women, and mother's age of death may be more predictive than father's age at death. Conclusion: Cohort predictors for exceptional survival may be different from those identified in comparisons with younger cohorts.

### HEALTHY COGNITIVE AGING: A CROSS-NATIONAL COMPARISON OF CIRCULATING MICRONUTRIENT CONCENTRATIONS

H. Dodge[1,5], Y. Katsumata[2], H. Todoriki[2], D. Willcox[3,7], B. Willcox[7,6], J. Kaye[1], M. Traber[4], *1. Oregon Health & Science University, Portland, Oregon, 2. University of Ryukyus, Okinawa, Japan, 3. Okinawa International University, Okinawa, Japan, 4. Linus Pauling Institute, Oregon State University, Corvallis, Oregon, 5. University of Michigan, Ann Arbor, Michigan, 6. The Queen's Medical Center, Honolulu, Hawaii, 7. Pacific Health Research Institute, Honolulu, Hawaii*

Objective: To examine whether there is any uniform pattern of circulating micronutrients cross-nationally that are associated with healthy cognitive aging defined as "having no cognitive impairment at age 85 and above". Design: A pilot study to compare the pattern of circulating levels of micronutrients among cognitively healthy oldest-old in Okinawa and the U.S. Results: The Okinawan elderly used fewer vitamin supplements but had similar levels of vitamin B12 and $\alpha$-tocopherol, compared with Oregonian elderly. The Okinawans had lower folate and $\gamma$-tocopherol, and a higher proportion of subjects with hyperhomocysteinemia. On the other hand, the Oregon elderly had a much higher prevalence of obesity. Conclusions: There were significant differences in circulating micronutrient levels between the two cohorts. A uniform pattern of circulating micronutrient levels might not be required to achieve healthy cognitive aging. Alternatively, the differential selection/survival process over the life course could have led to these cross-national differences.

### IOWA 2: BLOOD BIOCHEMISTRY AND THE PREDICTION OF SURVIVAL IN THE IOWA-EPESE

R.B. Wallace[3], A. Dutta[1], J. Guralnik[2], D. Melzer[1], *1. Epidemiology and Public Health, University of Exeter, Exeter, United Kingdom, 2. National Institute on Aging, Bethesda, Maryland, 3. University of Iowa, Iowa City, Iowa*

Aim: To identify blood and biochemistry markers predicting long-term survival. Methods: Data were from Iowa-EPESE. We included hematology and biochemistry on up to 1748 respondents examined at wave 6 of the study. We used Cox proportional hazard models to identify the significant markers predictive overall, and in different time periods from wave 6. Results: After adjustment for baseline age, sex, smoking status, income level, education, the strongest individual predictors ($p<0.0001$) included: Albumin/Globulin ratio, chloride, creatinine, alkaline phosphataise, gamma-glutamyl transferase, glucose, high density lipoprotein, triglyceride, uric acid, white blood cell count, lymphocyte count, neutrophil count and red blood cell distribution width. Analyses of the role of these markers in short, medium and long term prediction of survival will be presented. IL6 and CRP concentrations (n=722) were not prominent predictors. Conclusion: Several clinical markers predict survival. Only certain aspects of lipid profile (excluding total cholesterol) were prominent predictors. Inflammatory markers were not prominent.

### NEW PREDICTORS OF EXCEPTIONAL HEALTH AND SURVIVAL FROM LONGITUDINAL DATA

A.I. Yashin[1,2], K.G. Arbeev[1], S.V. Ukraintseva[1,2], I. Akushevich[1], A. Kulminski[1], J. Kravchenko[2], D. Il'yasova[2], D. Wu[1], *1. Duke University, Center for Population Health and Aging, Durham, North Carolina, 2. Duke University, Duke Comprehensive Cancer Center, Durham, North Carolina*

Aim. To identify dynamic predictors of exceptional health and survival. Data and Methods. We use the Framingham Heart Study data (Original cohort, 5,209 individuals) to evaluate dynamic properties of individual age trajectories of physiological indices. We evaluated the rates of change for BMI, serum cholesterol, diastolic blood pressure, pulse pressure, pulse rate, hematocrit, and blood glucose at the age interval 40 — 60 years. For non-monotonic age trajectories, we evaluated the rates of increase and decline (after reaching the maximum), age at the maximum and the maximum value. Stratification and the Cox regression analyses were used to evaluate contribution of these variables to morbidity/mortality risks. Results. We found that dynamic variables evaluated for each of seven physiological indices contribute to exceptional health and longevity. Conclusion. Dynamic parameters describing age trajectories of physiological state could be considered as targets for preventive and treatment interventions aiming to improve population health and longevity.

### LATE-LIFE PREDICTORS OF HEALTHY SURVIVAL: THE HAWAII LIFESPAN STUDY

C. Bell[1], R. Chen[2], K. Masaki[1,2], P. Yee[1], Q. He[2], D. Curb[1,2], D. Willcox[3], B.J. Willcox[1,2,4], *1. Geriatric Medicine, John A. Burns School of Medicine, University of Hawaii, Honolulu, Hawaii, 2. Kuakini Medical Center, Honolulu, Hawaii, 3. Okinawa International University, Okinawa, Japan, 4. Queen's Medical Center, Honolulu, Hawaii*

Objective: To identify potentially modifiable late-life factors predicting healthy survival to age 85. Methods: The Hawaii Lifespan Study studied 1548 Japanese-American men, free of chronic disease, functional impairment and cognitive impairment at baseline, followed for 15 years (1991-2005). We compared factors in 3 groups: those who died before age 85 (n=354), those who survived to age 85 with either chronic disease or functional/cognitive impairment (n=635), and those with healthy survival to age 85 (n=559). Results: Stepwise logistic regression analyses demonstrated increased likelihood of non-survival to age 85 with high fibrinogen ($p=0.0005$), high pack years smoking ($p<0.0001$), poor self-rated health ($p=0.02$) and non-married status ($p=0.005$). There was increased likelihood of unhealthy survival with low ankle-brachial index ($p=0.002$), slower 10-foot walk time ($p=0.002$), high fibrinogen ($p=0.002$), lower education ($p=0.02$), and poor self-rated health ($p<0.0001$). Conclusions: Potentially modifiable factors in late-life were significantly associated with survival to age 85 and healthy survival.

## SESSION 110 (SYMPOSIUM)

### DNA DAMAGE IN AGING AND CANCER

Chair: *G.J. Lithgow, Buck Institute for Age Research, Novato, California*

Co-Chair: *H.M. Brown-Borg, University of North Dakota, Grand Forks, North Dakota*

Damage to DNA has long been considered a cause of aging phenotypes and is certainly a major contributing factor to cancer. The emerging molecular and cellular details are beginning to explain the complex relationships at play. Not only DNA damage itself but the cellular machinery that responds to DNA damage is proving important for aging. This session will explore the emerging science and consider the link to epigenetic changes. Speakers: Judith Campisi, The Buck Institute Mario Fraga, Spanish National Cancer Centre CNIO Laura Niedernhofer, University of Pittsburgh School of Medicine

## SESSION 115 (SYMPOSIUM)

### ACADEMIC MODELS OF INTERGENERATIONAL LEARNING AND RESEARCH

Chair: *R. Hanks, Sociology, Anthropology & Social Work, University of South Alabama, Mobile, Alabama*

Discussant: *H.L. Sterns, University of Akron, Akron, Ohio*

Intergenerational learning and research projects are occurring in a diverse array of academic and community settings. Service-learning is a popular method of delivery for intergenerational experiences in academic settings. Other strategies are emerging for academic and civic engagement across generational lines, including co-learning classrooms to bring older and younger students together formally or informally and community-based research projects to empower members of each generation to influence research design and dissemination. This AGHE-sponsored symposium will describe multiple projects and the methods used to evaluate their impact on students, elders, and communities. Presenters will review challenges and rewards of interacting with community-based organizations in bringing academic research, service-learning, and co-learning experiences to multi-generational target groups in communities.

### OVERVIEW OF THE FIELD OF INTERGENERATIONAL LEARNING AND RESEARCH

S. Newman, *University of Pittsburgh, Pittsburgh, Pennsylvania*

This presentation provides a brief description of the history and rationale for intergenerational learning and discusses the current availability of research that provides insights into the content and cultural diversity of intergenerational learning. Information presented includes the development of the concept of intergenerational learning from US and International perspectives.

### INTERGENERATIONAL CO-LEARNING STRATEGIES AT THE UNIVERSITY LEVEL

L.K. Donorfio, B.G. Chapman, *Human Development and Family Studies, University of Connecticut, Waterbury, Connecticut*

Three different types of intergenerational co-learning experiences or exemplars will be highlighted at the university level: traditional class with accompanying field trip (urban and community studies class); interactive technology (iTV) class at three different locations (adult development and aging class), and a one day biology lab pairing lifelong learners with traditional college age students (biology class). Qualitative information was gathered and outcomes will be highlighted. The many challenges and rewards will be discussed.

### IMPLEMENTATION AND EVALUATION OF GERONTOLOGY STUDENT PROJECTS ACROSS A DIVERSE ARRAY OF SETTINGS

K. Kopera-Frye[1], R.L. Lee[2], *1. Dept. of Gerontology, Sociology, & Political Science, University of Louisiana at Monroe, Monroe, Louisiana, 2. University of Nevada-Reno, School of Community Health Sciences, Reno, Nevada*

Intergenerational Learning Projects are occurring in a diverse array of senior settings (e.g., assisted living housing, long-term care facilities). They differ along dimensions of site, structure, generations involved, student requirements, and evaluation methods. This paper will describe multiple cohorts of graduate and undergraduate university student service learning projects and a method used to evaluate their projects, from the perspectives of both the student and the elder. Both qualitative and quantitative measures are utilized in the evaluation. Lessons learned from these projects in terms of their organization and evaluation will be shared. Recommendations addressing these challenges (e.g., appropriate level of project for type of senior population) will be reviewed.

### INFUSING INTERGENERATIONAL LEARNING AND RESEARCH INTO COMMUNITY-BASED PARTICIPATORY PROJECTS: A COMMUNITY HEALTH ADVOCACY MODEL

R. Hanks, *Sociology, Anthropology & Social Work, University of South Alabama, Mobile, Alabama*

Intergenerational learning and research are used in a Community Health Advocacy Program at the Center of Excellence, University of South Alabama. This presentation reports on the community-based participatory research context in which the program developed; growth of the program; strategies for program evaluation; and outcomes within and across generations involved in the project. The emphasis is on intergenerational co-participation in community-based research and advocacy.

## SESSION 120 (SYMPOSIUM)

### ATTACHMENT PROCESSES IN LATE LIFE

Chair: *J. Monin, University of Pittsburgh, Pittsburgh, Pennsylvania*
Discussant: *V.G. Cicirelli, Purdue University, West Lafayette, Indiana*

Attachment theory stipulates that the need for relationship security is one of the most fundamental of all basic needs for people of all ages, and it provides a basis for understanding complex interpersonal dynamics throughout the lifespan. Although attachment theory has stimulated an enormous body of empirical research during infancy, childhood, and early adulthood, research on late life relationships using this perspective has been relatively limited. We show that attachment theory can inform a variety of interpersonal processes in older adulthood. The first presentation will provide a definition of attachment and discuss measurement issues unique to studying attachment in older adults. Data will be presented describing specific attachment functions (e.g., safe haven and secure base support) of close partners of older adults. The second presentation will show how attachment styles and gender relate to emotional experiences in a sample of older adults from seven ethnic groups. The last two presentations will discuss how attachment security relates to experiences of chronically ill older adults and their caregivers. Specifically, research on associations between attachment and pain, psychological adjustment, and coping in patients with persistent pain and cancer will be presented in the penultimate talk. The final presentation will describe a laboratory study demonstrating that insecurely attached spouses of older adults with osteoarthritis experience heightened distress and are hyper-vigilant to signs of their partner's suffering. The aim of this symposium is to draw attention to the utility of attachment theory for understanding how relationship processes influence well-being in late life.

### DEFINING AND MEASURING ATTACHMENT IN LATE LIFE

J.Q. Morse, *Western Psychiatric Institute & Clinic, University of Pittsburgh, Pittsburgh, Pennsylvania*

Attachment theory (Bowlby, 1977) was formulated as a model of infant-caregiver bonds. The extension of attachment theory to adult relationships, not only with parents but also with romantic partners, and into later life raises questions about what relationships may be attachment relationships and how such attachments should be assessed to understand attachment in late life. This presentation will review issues in conceptualizing and assessing attachment in older adults. I will focus on the validity and utility of both self-reported and other reported attachment style, reporting preliminary data on different adult attachment measures. In addition, I will describe attachment functions and features (separation distress, proximity maintenance, safe haven, secure base) of reported by older adults. Potential clinical applications will be described by examining the relation between dimensional and categorical attachment styles and mental health outcomes like caregiver burden, depressive symptoms, and course of treatment for depression.

### GENDER MODERATES THE ASSOCIATIONS BETWEEN ATTACHMENT AND DISCRETE EMOTIONS IN LATE MIDDLE AGE AND LATER LIFE

K. Fiori[1], N. Consedine[2], *1. Gordon F. Derner Institute of Advanced Psychological Studies, Adelphi University, Garden City, New York, 2. University of Auckland, Auckland, New Zealand*

Although attachment has been linked to emotions, studies in developmentally diverse samples are few and have not yet examined possible gender differences in attachment or their implications for emotional well-being. Using a sample of 616 men and women from seven ethnic groups in middle age and later life, we examined the relations between attachment and the experience of nine discrete emotions, testing the hypothesis that gender moderates these associations. Regressions showed that gender did indeed moderate these associations such that (a) attachment security was more closely related to interest and joy among men; (b) fearful avoidance was more closely related to fear and contempt among men; and (c) preoccupation was associated with greater interest among men, whereas fear and contempt were associated with preoccupation among women only. We suggest that attachment styles may differentially predict male emotions because of their less diverse networks and greater reliance on attachment figures.

### ATTACHMENT IN THE CONTEXT OF PAIN AND CANCER: IMPLICATIONS FOR PATIENTS AND THEIR CAREGIVERS

L. Porter[1], M. Rumble[1], F. Keefe[1], D. Davis[2], C. Scipio[1], J. Garst[1], *1. Duke University Medical Center, Durham, North Carolina, 2. University of Nevada, Reno, Nevada*

Individuals suffering from medical conditions such as cancer and persistent pain experience frequent and persistent threats to their well-being which are likely to trigger attachment behaviors in both themselves and their informal caregivers. Thus, patient and caregiver attachment styles may impact their adjustment to the patient's disease. This paper will present an overview of research examining associations between attachment and pain, psychological adjustment, and coping in patients with persistent pain and cancer. Data from a recent study of lung cancer patients and their spouses will be presented. Results from this study indicated that patient anxious and avoidant attachment styles were associated with higher levels of psychological distress and lower social functioning. Among spouses, anxious and avoidant attachment were associated with higher levels of caregiver strain, and avoidant attachment was also associated with lower levels of marital quality and self-efficacy. Clinical implications and avenues for future research will be discussed.

### ATTACHMENT INSECURITY AND PERCEIVED PARTNER SUFFERING AS PREDICTORS OF CAREGIVERS' FEELINGS OF PERSONAL DISTRESS

J. Monin[1], R. Schulz[1], B.C. Feeney[2], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, 2. Carnegie Mellon University, Pittsburgh, Pennsylvania*

This study examined the extent to which perceptions of partner suffering mediate the association between attachment insecurity (anxiety and avoidance) and personal distress among caregiving spouses of older adults with osteoarthritis. Fifty-three caregivers watched two videos of targets (their partner and an opposite sex stranger) performing a pain-eliciting household task, and caregivers were asked to rate their own distress and perceptions of the targets' pain. Caregivers also completed self-report measures of trait attachment and perceptions of their partner's physical, psychological, and existential/spiritual suffering over the past week and their own depressive symptoms. Results revealed that attachment anxiety was associated with greater personal distress in reaction to watching the partner in pain (but not the stranger), and heightened perceptions of partner pain mediated this association. Perceptions of the partner's psychological suffering over the past week also mediated the link between caregivers' attachment anxiety and depressive symptoms. Attachment avoidance was not significantly associated with distress. The results of this study indicate that anxiously attached individuals may be at a higher risk for the negative health effects of caregiving.

## SESSION 125 (SYMPOSIUM)

### BRIGHTEN PROGRAM: OUTCOME AND IMPLICATIONS OF AN INTERDISCIPLINARY TEAM FOR OLDER ADULT DEPRESSION INTERVENTION

Chair: *E.E. Emery, Rush University Medical Center, Chicago, Illinois*
Discussant: *F. Blow, University of Michigan, Ann Arbor, Michigan*

BRIGHTEN (Bridging Resources of an Interdisciplinary Geriatric mental Health Team via Electronic Networking) is a unique interdisciplinary "virtual" team model that screens for, assesses, and treats depression and anxiety among older adults through integration in primary care. Recognizing the diverse needs of older adults, our team includes disciplines not ordinarily participating directly in mental health intervention. The BRIGHTEN program has been operating in primary and specialty care clinics at a university medical center, a county clinic serving the under- and uninsured, and a Hispanic clinic serving primarily Spanish-speaking under- and uninsured individuals. Outcome data are presented that indicate higher engagement rates than community mental health centers, and clinically and statistically significant psychotherapy outcomes in three months of treatment. Both participants engaging in psychotherapy and those utilizing other BRIGHTEN services move from high symptom levels at baseline into the normal range within three months and maintain gains at six months. These findings are consistent across a wide range of ethnic, socioeconomic, and educational status older adults. Data will also be presented indicating that providing general psychotherapy outcome data to potential participants making treatment decisions is associated with increased engagement rates. The BRIGHTEN Program addresses many key policy and care model issues in mental health and aging. The impact of BRIGHTEN's primary care integration, reducing disparities in access to evidence-based treatment, and increasing the geriatric mental health workforce on local, state, and national policy will be discussed.

### PSYCHOTHERAPY OUTCOME AND ENGAGEMENT IN THE BRIGHTEN PROGRAM

E.E. Emery, S. Robertson, *Rush University Medical Center, Chicago, Illinois*

Few of the 15%-25% of older adults reporting depressive symptoms at a level considered to be clinically significant receive adequate treatment. Even when services are available, only 70% at best show up for treatment in community mental health treatments. The BRIGHTEN program is an interdisciplinary, virtual team model program designed to screen for, assess, and treat depression and anxiety among older adults in primary care. BRIGHTEN has demonstrated an 85% show rate for assessments and 95% show rate for psychotherapy. Preliminary data indicate that participants (N=39; Mean age = 69.70 years, SD = 7.75, range = 60 – 91) receiving cognitive behavioral or interpersonal psychotherapy demonstrated significant improvements in symptoms of depression (PHQ-9, $p < .01$) and anxiety (Beck Anxiety Inventory, $p < .05$) within three months of treatment onset. Implications of the interdisciplinary team approach to mental health intervention for engagement and symptom reduction are discussed.

### EFFECTIVENESS OF AN INTERDISCIPLINARY APPROACH IN MANAGEMENT OF DEPRESSION IN DIVERSE SOCIOECONOMIC POPULATIONS

G. Rodriguez-Morales, I.I. Ivan, E. Woodhead, R. Golden, E.E. Emery, *Rush University Medical Center, Chicago, Illinois*

Age and poverty are risk factors for depression. These variables interact with language barriers and limited access to resources, further interfering with the effective management of depression. The goal of the current study was to examine the differential effectiveness of the BRIGHTEN Program, an interdisciplinary approach to depression treatment, among historically advantaged and disadvantaged older adult populations. Data were analyzed from 30 patients served in a private, nonprofit medical center (PRMC) and 20 patients from public health centers serving under/uninsured populations (PHCs). These two groups differed in age ($p < 0.01$), education ($p < 0.001$), and insurance status ($p < 0.001$). There were also group differences in poverty level and employment status. The PHQ-9 score in PRMC and PHCs patients improved significantly ($p < 0.05$ on both). Therefore, despite differences in risk factors and challenges for management, both groups achieved reduction in depressive symptoms through participation in the BRIGHTEN Program.

### BRIGHTEN: THE EFFECTIVENESS OF A PATIENT-CENTERED INTERDISCIPLINARY TEAM IN IMPROVING MENTAL HEALTH

I.I. Ivan, A. Eisenstein, E.E. Emery, G. Rodriguez-Morales, *Rush University Medical Center, Chicago, Illinois*

By 2030, an estimated 20% of older adults in community settings will experience significant depressive symptoms. The aims of the study were to determine whether the BRIGHTEN intervention is effective in improving mental health and to examine how mean scores on mental health measures compare to the average U.S population norm mean for adults over the age of 60. SF12-Mental Component Score (MCS) and Geriatric Depression Scale (GDS) scores significantly improved from baseline (n= 60) to 3 month ($p<.05$, $p<.001$ respectively) and to 6 month follow-up ($p<.05$, $p<.001$, respectively). SF12-MCS scores were significantly below the 25th percentile mean at baseline. By the 6 month follow-up, patients were within the normative mean range. Psychotherapy patients did not have significantly different SF12-MCS or GDS scores from those patients involved in other BRIGHTEN interventions. The clear effectiveness of the patient-centered interdisciplinary team in improving mental health is further discussed.

### INCREASING ENGAGEMENT IN DEPRESSION TREATMENT FOR OLDER ADULTS: EVIDENCE FOR INCORPORATING TREATMENT OUTCOME DATA

E. Woodhead, I.I. Ivan, E.E. Emery, L.F. Fogg, *Behavioral Sciences, Rush University Medical Center, Chicago, Illinois*

The current study examined the relative weight assigned to treatment outcome data, personal, and vicarious experience among older adults deciding whether to initiate treatment for depression. Twenty-five adults over age 60 completed a structured interview about their decision making process. Among those reporting personal or vicarious experience with depression treatment (n = 17), treatment outcome data was ranked as significantly more important than experience in the decision making process, $t(16) = 2.99$, $p < 0.01$. This was not impacted by numeracy. Forty percent of participants requested clarification of the data; fifty-two percent reported that the treatment outcome data increased hope for successful treatment. Participants reporting that the treatment outcome data increased feelings of hopefulness had higher rates of psychotherapy engagement (75.0% vs. 54.5%). These results suggest that providing outcome data may increase motivation for depression treatment, particularly if the outcome data are tailored to the individual's level of understanding.

### POLICY IMPLICATIONS OF BRIGHTEN PROGRAM PROCESS AND OUTCOMES

R. Golden*, Older Adult Programs, Rush University Medical Center, Chicago, Illinois*

The BRIGHTEN Program addresses many key policy and care model issues in mental health and aging. First, the program improves access to care for underserved older adults by integrating mental health services into primary care through outreach. Second, the quality of care is improved by implementing evidence-based practices. Through these practices, BRIGHTEN reduces disparities of care with racially and ethnically diverse older adults. Finally, we are building workforce capacity by training new and current practitioners in evidence-based geriatric mental health practices. Issues discussed will include methods of influencing policy to sustain this model, and demonstrating to key stakeholders the value of the concept and the outcomes. Our national, state and local strategies through coalitions, advocacy and business plans will be discussed in an attempt to impact reimbursement sources, legislators, and funders.

## SESSION 130 (PAPER)

## DIABETES

### UNDIAGNOSED AND POORLY TREATED DIABETES AND HYPERTENSION AMONG OLDER CAREGIVERS

L.E. Best, L. Baker, *Andrus Gerontology Center, University of Southern California, Los Angeles, California*

Prior research suggests that caring for a family member is associated with poor health outcomes, including high rates of mortality. We propose that older adults providing excessive levels of care for grandchildren, parents, and spouses are more likely than non-caregivers to neglect their health, resulting in undiagnosed and poorly managed disease. Using the 2006 Health and Retirement Study, we examine both self-reports and biological markers of diabetes and hypertension among three groups of older adults (N=6,008): 1) those providing high (15+ hrs/week), 2) moderate (1-15 hrs/week), and 3) none/low (<1 hr/week) levels of family care. Hours of family care were defined as the total number of hours a respondent reports providing care for his/her grandchildren, parents, and/or spouse. Undiagnosed conditions were defined by whether respondents were ever told by a health professional that they had diabetes or hypertension, but exhibited high levels for that condition (HbA1c glycosylated hemoglobin for diabetes and automated inflatable cuff blood pressure reading for hypertension). Individuals reporting that a health professional diagnosed them as well as high readings for the corresponding biological marker were classified as having a poorly managed condition. We employ a series of logistic regression analyses controlling for demographic and socioeconomic characteristics. Results suggest that individuals providing moderate levels of care have a lower likelihood of having undiagnosed and poorly managed disease. The results of this study demonstrate not only the importance of biological marker data in population surveys but also the need to understand the extent to which caregiving affects disease diagnosis and management.

### USE OF COMPLEMENTARY AND INTEGRATIVE THERAPIES IN OLDER ADULTS WITH DIABETES

R.R. Whitebird[1], S.E. Asche[1], P.J. O'Connor[1], M. Kreitzer[2]*, 1. HealthPartners Research Foundation, Minneapolis, Minnesota, 2. University of Minnesota, Minneapolis, Minnesota*

Little is known about how older adults use complementary and integrative therapies for chronic health conditions and overall health. We surveyed a random sample of 2000 older adults with diabetes in a Midwest medical group regarding their use of complementary therapies. We had a 57% response rate following exclusion of ineligibles, with 54% reporting some use of complementary therapies in the prior year. Those using these therapies were younger, female, more educated, more likely to be employed, younger at age of diabetes diagnosis and had a higher BMI than those not using complementary therapies. They also reported lower levels of physical and mental health and a higher percentage reported slow healing foot ulcers. There were no differences in glycated hemoglobin (A1c) levels between groups and both reported high levels of having a regular primary care doctor, trust in their doctor and satisfaction with their health care. Only 24% of those using complementary therapies report discussing this with their doctor. Those using complementary therapies were less likely to follow their doctor's advice, and reported greater belief in the concept of holistic health and in the scientific validity of complementary therapies. The most frequently reported type of complementary therapies used were mind/body therapies such as meditation and deep breathing exercises (30%); 35% of those using complementary therapies (or 19% of all respondents) reported using them specifically for their diabetes. Results indicate that high proportions of older adults with diabetes are using complementary and integrative therapies for their diabetes and their overall health.

### DIABETES AND SELF-RATED MENTAL HEALTH: THE ROLE OF AGE AND RACE

G.M. McCaskill[1,3], C.B. Worley[2,3], G. Kim[3,2], J. DeCoster[3]*, 1. The University of Alabama, School of Social Work, Tuscaloosa, Alabama, 2. The University of Alabama, Department of Psychology, Tuscaloosa, Alabama, 3. School of Social Work, The University of Alabama, Center for Mental Health and Aging, Tuscaloosa, Alabama*

This study examined how socio-demographic characteristics and diabetes are associated with self-rated mental health among White and Black older adults in the United States. Data were drawn from a national multi-stage probability sample, the Collaborative Psychiatric Epidemiology Surveys (CPES, 2001-2003). General linear modeling was used to assess the interaction effect of age, race, and diabetes on self-rated mental health. Results showed a significant main effect of income, education, diabetes, and religiosity on self-rated mental health. After controlling for income, education, and religiosity, the significant interaction effects of age x diabetes and age x race were found. Older Blacks with diabetes had poorer self-rated mental health compared to older Whites with diabetes. Older Whites without diabetes had better self-rated mental health compared to older Blacks without diabetes. Findings suggest that self-rated mental health is influenced by diabetes and these associations appear to be different in older Whites and Blacks. Implications for research, practice, and policy in the area of diabetes and aging are discussed.

# SESSION 135 (POSTER)

## DIVERSE POPULATIONS

### NAVIGATING THE HISPANIC PARADOX: EXPLORING MIGRATION EFFECTS ON THE HEALTH STATUS OF MEXICANS

M. Rivera-Hernandez, *Gerontology, Miami University, Oxford, Ohio*

Since the 1980s several studies have found support for the Hispanic mortality advantage or Hispanic paradox (Markides & Coreil, 1986). In general research has shown that low socioeconomic status is strongly associated with poor health and mortality outcomes; however, the Hispanic paradox posits that Hispanic adults living in the U.S. have lower mortality rates than non-Hispanic whites even when Hispanics have lower socioeconomic status. One of the explanations for this paradox is related to migration. According to the salmon-bias hypothesis, the mortality advantage might be linked to the return migration of foreign-born Hispanics who return to their country of origin when they reach advanced age so that they can receive treatment there for illnesses, or can return home to spend their last days in their own country. The goal of this paper is to investigate the difference in health status (self-rated health) between people who lived in the United States and went back to Mexico and people that never left Mexico. The analyses are based on data from the Mexican Health and Aging Study (MHAS), a unique longitudinal dataset which addresses health dynamics based on history of residence. There is a clear relationship between location of residency, migration history, and health status of Mexicans. The results suggest that Mexicans who lived in the U.S. and returned to Mexico are more likely to have better health than their counterparts. This type of information may be useful to researchers that try to explain the Hispanic paradox and its link to successful aging.

### THE IMPACT OF PLACE OF EDUCATION ON HEALTH IN MEXICAN AMERICANS OVER 50 YEARS OF AGE

C.L. LaCoe, L.A. Wray, *The Pennsylvania State University, University Park, Pennsylvania*

Introduction: Strong, positive relationships between educational attainment and most measures of health exist, and even strengthen, throughout the lifespan. However, these relationships are attenuated in some social groups and are poorly understood. The aims of this study are to 1) examine the relationships between low education attainment and five health outcomes (heavy alcohol consumption, being a smoker, physical inactivity, obesity, diabetes) in first generation Mexican Americans over age 50, and 2) determine if place of education (U.S. vs. Mexico), a determinant of cultural capital, mediates these relationships, controlling for key covariates. Methods: We used panel data from Wave 4 (1998; n=298) and Wave 7 (2004; n=239) of the nationally representative Health and Retirement Study (HRS) and logistic regression analyses to address our aims. Results: Low educational attainment and education in Mexico did not significantly predict physical inactivity, obesity, smoking, or diabetes prevalence or incidence. However, low educational attainment significantly decreased the odds of heavy alcohol consumption ($OR=0.591$, $p<0.01$), net of other covariates. Marital status, gender, age, health behaviors, and comorbidity significantly, but differentially, influenced the odds of the health outcomes. Conclusions: Contrary to findings in samples of Asian American immigrants, educational attainment and place of education were not significantly related to most measures of health in Mexican American immigrants. This may be due to the surprisingly low levels of and variability in educational attainment and the small size of the sample. Our findings highlight the importance of studying indicators of health separately, as well as looking at specific subpopulations of immigrants.

### OLDER AFRICAN AMERICANS' STRATEGIES FOR COPING WITH ADVERSITY: SERVICE AND RESEARCH IMPLICATIONS

A. Schwartz[1], L.N. Gitlin[2], C.J. Caruso[2], J. Burke[2], *1. Boston College, Graduate School of Social Work, Chestnut Hill, Massachusetts, 2. Thomas Jefferson University, Center for Applied Research on Aging and Health, Philadelphia, Pennsylvania*

Existing coping scales are limited in their ability to capture culturally specific adaptive mechanisms used by diverse groups of elders. This is particularly the case for African American elders, for whom coping measures are primarily undeveloped and under validated. In addition, African American elders use and prefer unique coping strategies reflecting resilience to historical and present day adversities typically not reflected in existing measures of coping. A semi-structured qualitative interview was used to identify coping strategies to manage daily challenges of growing old among 30 African American elders. These adversities included functional changes, neighborhood crime, personal safety, and feeling sad or blue. Transcribed interviews were reviewed and coded for domains and topics reflecting approaches to coping, then analyzed further through use of Nvivo8 qualitative software. Analyses revealed 10 domains reflecting distinct approaches to coping with challenges. Some domains are represented in standardized coping scales and include: emotional and physical health management, cognitive reframing, purposeful engagement, relying on one's faith, relying on self, environmental and behavioral strategies, and social connectedness. Others appear unique to this group and include: future think, setting boundaries, and the problem resolving itself. Purposeful engagement was particularly highly utilized among respondents. Knowledge of culturally specific forms of adaptation adds to the discourse on coping and brings into question the adequacy of existing scales used to shape service delivery. Findings from this study suggest the need for systematic examination of the preferred and unique coping styles of diverse elders to inform intervention development. (NIMH # R24 MH074779)

### HEALTH LITERACY 101: CULTURE, EDUCATION, AND HEALTH CARE SYSTEM DO MAKE A DIFFERENCE

B. Flores, *University of Texas at Austin, University of Texas Health Science Center San Antonio, San Antonio, Texas*

ABSTRACT Background: Hispanic women suffer from higher rates of cervical cancer when compared to white women in the United States. Purpose: Review qualitative and quantitative studies addressing the relationship of cervical cancer screening with possible points of intervention according to the Institute of Medicine (IOM) model. These points are culture and society, the education system, and the health care system and its association with health outcomes. Methods: A literature search in CINAHL Plus With Full Text, Medline and ERIC was conducted using the search terms: cervical smear+, cancer screening, pap smear, Hispanic, and health literacy, from 1997 to 2007. The search was updated in CINAHL Plus with Full Text, Ovid Medline, Pub Med and ERIC to include the years between 1996 and 2009 using the search terms literacy, health literacy, cervical smears+, pap smears, vaginal smears, cancer screening, mass screenings, female, Hispanics+, Hispanic-American+, health care, health care cost, cost, and health education, from 1996-2009. Study Selection: A total of 140 articles were reviewed; of those, 56 met inclusion criteria. Findings: An association was found between low literacy, low education, decreased knowledge, low acculturation, lack of health insurance, fear, older Mexican women, and decrease utilization of Pap smear screening. Conclusion: There is a need to continue research targeted to improve health care outcomes and decrease mortality rates among the most vulnerable populations of older Mexican-American women and to develop educational tools and strategies aimed at Hispanic women with low literacy.

### RACIAL/ETHNIC DISPARITIES IN ANXIETY SYMPTOM SEVERITY: A STRESS PROCESS MODEL

C.B. Worley[1,2], R.S. Allen[1,2], G. Kim[1], M. Stenner[1], *1. Department of Psychology, University of Alabama, Tuscaloosa, Alabama, 2. Center for Mental Health and Aging, Tuscaloosa, Alabama*

As the nation becomes more diverse in both age and racial and ethnic group membership, unique challenges emerge in understanding health disparities. Research has suggested that as racial and ethnic minority groups from newly immigrant populations acculturate, their rates on mental illness rise. The purpose of this study was to examine anxiety symptom severity across diverse racial/ethnic groups. Data were drawn from the Collaborative Psychiatric Epidemiology Surveys (CPES, 2001-2003) dataset, which is one of the first to provide national data with enough power to explore cultural influences on mental health in a racial and ethnic minority sample (Colpe, et al, 2004). The Stress Process Model was used to assess factors associated with the development of anxiety symptoms in the following racial/ethnic groups separately: Vietnamese, Filipino, Chinese, Other Asians, Cuban, Puerto Rican, Mexican, Other Hispanics, Afro-Caribbean, African-American, Non-Latino Whites, and Other. Data were analyzed with Structural equation modeling (SEM). In the model, anxiety symptom severity was predicted by demographic variables, objective stressors, subjective stressors, intrapsychic strain, role strain, and resources. Differences in the model fit across diverse racial/ethnic and age groups are discussed. Implications for intervention programs and public policy are discussed in the cultural context.

### RURAL CULTURE AND HEALTHCARE UTILIZATION

J.A. Zimmerman, B. Mast, *Psychological and Brain Sciences, University of Louisville, Louisville, Kentucky*

Literature on rural health often states that compared to their urban counterparts, rural residents have a unique culture that may impact healthcare utilization (HCU). However, empirical evidence supporting this belief is lacking. The current study investigated the association between HCU and two cultural variables believed to be more relevant in rural communities: self-efficacy and negative attitudes (NAs) towards doctors. Level of rurality was measured by the USDA Economic Research Department's rural-urban continuum codes and resulted in four independent groups. Participants included 4,162 individuals from the Duke EPESE study. As predicted, one-way analysis of variance revealed NAs significantly differed across the four levels of rurality ($p < 0.001$). Although there was a general trend for greater NAs as rurality increased, post-hoc analyses indicated significant differences only between the most rural group and the three other groups ($p < 0.001$, for all three comparisons). Urban residents also reported greater self-efficacy compared to more rural residents ($p = 0.03$). Bivariate correlations demonstrated a significant relationship between self-efficacy and HCU ($p < 0.001$), such that higher levels of self-efficacy were associated with fewer doctor visits over the previous 12 months. NAs were not significantly associated with HCU. These findings suggest cultural aspects of rural residence are important in understanding differences between urban and rural older adults in terms of HCU. Further, the significant variation in cultural attitudes by level of rurality (as a continuum) suggests a dichotomous measure of rural/urban may be insufficient and that researchers should utilize a more detailed rural/urban classification system.

### RACIAL/ETHNIC DIFFERENCES IN LONG-TERM CARE SERVICES USE BY FRAIL ELDERS

Y. Ji[1], D.A. Chiriboga[2], G. Mitchell[3], *1. School of Aging Studies, University of South Florida, Tampa, Florida, 2. Louis de la Parte Florida Mental Health Institute, University of South Florida, Tampa, Florida, 3. The Claude Pepper Center, Florida State University, Tallahassee, Florida*

Using Florida Medicaid claim & eligibility data from fiscal year 1998-99 to 2007-08, the present study examined the different patterns of use of institutional and home- and community- based long-term care services by African American, Hispanic, and White frail elders. Under the same need characteristics, older African Americans were found less likely to use nursing home than their white counterpart, with older Hispanics being the least likely to use nursing home. Older Hispanics were found less likely to use home- and community-based services than their white and black counterparts. Older African Americans and Hispanics who newly entered Florida home and community alternatives in fiscal year 2004-05 were found more likely to die during the follow-up 36 months and less likely to end up in nursing home. Older Whites who newly entered nursing home in fiscal year 2004-05 were more likely to have previous experience using home- and community-based services over the previous 36-month period and have longer duration in nursing home over the follow-up 36 months. Over the ten year period, both use of nursing home and home- and community-based services among older Hispanics showed a steady upward trend while little variation was indicated for white and African American groups over time.

### RISK OF INCIDENT HYPERTENSION AMONG BLACK, WHITE, AND MEXICAN AMERICANS AFTER AGE 50

A.R. Quinones[1], J. Liang[1,2], W. Ye[1], *1. University of Michigan, Ann Arbor, Michigan, 2. Institute of Gerontology, Ann Arbor, Michigan*

There is extensive research on the prevalence of hypertension. However, information regarding incident hypertension among older individuals is more limited, particularly those involving minority groups over an extended period of time. This research examines the risk of developing hypertension for Americans over age 50 for a period of up to 10 years. It focuses on how incidence in self-reported hypertension varies across white, black and Mexican Americans. Data came from 9,547 respondents who were hypertension-free at the baseline in the Health and Retirement Study with up to six repeated observations (1996-2006). Discrete-time survival models were used to analyze ethnic variations in the probability of developing hypertension. The probability of incident hypertension among black Americans was 0.10 during the period of 1996-1998, which increased steadily to 0.16 during 2004-2006. In contrast, among white Americans the risk was 0.08 during 1996-1998 and 0.13 during 2004-2006. For Mexican Americans, the probability increased from 0.07 during 1996-1998 to 0.12 during 2004-2006. During the same period, there were no significant ethnic variations in the risk of dying. The risk of newly diagnosed hypertension increased between 1996 and 2006 for all Americans over 50. To a significant extent this increase was a result of changing demographic and health attributes. Relative to white and Mexican Americans, black Americans had an elevated risk of incident hypertension throughout the 10-year period of observation. These variations persisted even when differences in health behaviors, socioeconomic status, demographic, and time-varying health characteristics were adjusted.

### EXPLORING THE REASONS AFRICAN AMERICAN AND RURAL-DWELLING ELDERS PARTICIPATE IN MEMORY RESEARCH

A. Hunsaker[1], C. Sarles[2], D. Rosen[1], J. Lingler[3,2], M. Johnson[4], L. Morrow[2], J. Saxton[2], *1. School of Social Work, University of Pittsburgh, Pittsburgh, Pennsylvania, 2. University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, 3. University of Pittsburgh School of Nursing, Pittsburgh, Pennsylvania, 4. Bonacile Enterprises, Pittsburgh, Pennsylvania*

African Americans and rural-dwelling older adults have been historically underrepresented in both community and university-based memory research, leading to a lack of normative data for these populations. Yet, both African Americans and rural-dwelling individuals may represent a large percentage of those who develop dementia in later life. This study examines how older African Americans and rural-dwelling individuals conceptualize the reasons for study participation, particularly in mild cognitive impairment and dementia studies that employ recruitment programming to enhance study participation from these populations. Nine focus groups were held with African Americans and rural-dwelling older adults (N=55) who had participated in a community-based memory screening study. Forty-two percent of focus group participants had additionally participated in a comprehensive memory assessment at a university-based Alzheimer Disease Center. Content analysis was employed using an inductive method of coding. The benefits of research participation were a predominant theme in all focus groups and were comprised of benefits to the participant, the participant's family and society. Participation in memory research was believed to lead to an understanding of memory function. Findings revealed that transportation to university-based study appointments was a key element in sustaining research participation for rural-dwelling elders, while financial compensation was important to African American participants. In light of recruitment mandates from the NIH, enhancing awareness of research opportunities among these communities will be a gain for both the participant and the advancement of effective dementia assessment and treatment strategies in our increasingly diverse population.

### AFRICAN AMERICAN FEMALE ELDERS LIVED EXPERIENCE WITH DEPRESSION: "DEPRESSION AFFECTS THE WHOLE BODY."

E.C. Ward, *School of Nursing, University of Wisconsin-Madison, Madison, Wisconsin*

Background: Among older African American women, depression is a major public health concern. More research is needed to examine African American elders' experiences with depression to increase treatment-seeking behaviors. Research Question: 1) What are older African American Females experiences with late-life depression? Methods: Study Design: Phenomenology, which is a method of inquiry that seeks a deeper understanding of the meaning of everyday experiences or phenomenon. Using phenomenology our goal was to understand the meaning (essence) of living with depression for African American women over 60 years. Sample: 13 African American women, mean age 72 years. Data Collection: Individual face-to-face interviews. Primary interview question: "Tell me about your experiences with depression." Follow-up questions were formulated based on responses to the primary interview question. Data Analysis: Analyzed each transcription separately and identified salient themes that appeared to capture participants' experiences with depression. Later analyzed all themes to identify areas where themes converged showing commonality of experiences. Results: The women made meaning (sense) of their depression by reflecting on causal factors (death of children, family-related stressors, and poor physical health) and symptoms (loneliness, sleep difficulties, and anger). Quotes capturing concerns about symptoms included "depression affects the whole body; one day you are happy and the next day you are down, like on a cycle). Implications: When working with African American women experiencing late-life depression it is important to get their perspective on causal factors and symptoms as understanding their perspective helps to facilitate trust and provision of culturally-sensitive, patient-centered care to this group.

### SOCIAL SERVICE NEEDS AND PERCEPTIONS OF LOW-INCOME LATINOS

M. Kaesemeyer, T.K. Amador, *Health Services Administration Dept., Regis University, Denver, Colorado*

Introduction: Social services are critical for older adults as they transition through care along the aging continuum. Access to social services is particularly important for low-income, minority populations who routinely experience health, social, and economic disparities (Kamble & Boyd, 2008). As a result, this study focused on social service needs and perceptions of low-income Latinos. Literature Review: Latinos are the largest minority group in the United States who frequently experience difficulty accessing social services due to language, cultural misunderstandings, discrimination, legal status, stigma, and other barriers (Ku, 2007).Methodology: Data were obtained through three focus group interviews in this qualitative study (Kaesemeyer, 2009). Seventy-five percent of participants (nine of twelve) were recruited from a community center's senior program. The focus group interviews were taped, transcribed, and analyzed utilizing content analysis to organize data into themes. Results: Central themes included challenges with accessing social services, negative emotions related to these challenges, and confusion around eligibility criteria (Kaesemeyer, 2009). Difficulty accessing social services was the most commonly discussed issue among these low-income Latinos. Words describing negative emotions of participants included frustration, disrespect, and sadness. Finally, low-income Latinos in this study perceived eligibility criteria to be inconsistent among providers, especially with regard to finances. Conclusions: Low-income Latinos encountered difficulty accessing social services and experienced a range of negative emotions as a result. It is clear that low-income Latinos in this study needed additional education and support to understand and access the services for which they are eligible. References: Kaesemeyer, M. (2009). Social service needs and perceptions of low-income Latinos in metro Denver. Unpublished master's thesis, Regis University, Denver. Kamble, S., & Boyd, A.S. (2008). Health disparities and social determinants of health among African-American women undergoing percutaneous coronary interventions (PCI). Journal of Cultural Diversity, 15(3), 132-142. Ku, L. (2007). Improving health insurance and access to care for children in immigrant families. Ambulatory Pediatrics, 7(6), 412-420.

### CULTURAL PERCEPTION OF ILLNESS

H. Ulatowska, B. Reyes, T. Santos, R. Varindani, *University of Texas at Dallas, Dallas, Texas*

When an individual becomes ill, he develops a need to make sense of his illness. In doing so, he links his personal life event to the bigger social environment in which he lives (Bury, 2001). From a clinical standpoint, illness narratives are of great value, in that, narratives bridge the gap between the person telling the illness and the listener (Charon, 2001). This value is further highlighted when dealing with individuals from different cultural backgrounds. The clinician is faced with the challenge of not only understanding the illness from the person's perspective, but also considering the cultural elements which define the individual and are vital to patient-doctor relationships. Given the importance of cultural sensitivity in medicine, this study deals with illness stories of individuals from four different cultural groups, namely: Caucasian Americans, Hispanic Americans, Filipino Americans and Indian Americans. It identifies common themes in illness stories, such as the vulnerability one experiences in illness and the importance of support structures (family/friends) to help cope with illness. The study also recognizes unique perspectives which are inherent in one's culture, such as the acceptance of one's condition, the importance of religion and the value of close family ties to name a few. The cultural perceptions of the roles of the people appearing in the illness narratives such as doctors, family members and friends are discussed.

### AGE, GENDER, AND ETHNIC DIFFERENCES IN DEPRESSION AND TRAIT ANXIETY AMONG DIFFERENT PRISON POPULATIONS

A. Begovic-Juhant, E.L. Collins, S. Bäck, *Health Sciences, Cleveland State University, Cleveland, Ohio*

This research examined age, gender, and ethnic differences in trait anxiety and depression among prison populations. Participants comprised of 140 males and females aged 25 to 81. Researchers submitted criteria for participation to the Ohio Department of Rehabilitation and Correction's (ODRC) office of Human Research. Inmates were randomly selected from four correctional institutions. They completed a semi-structured questionnaire consisting of demographics, established measures of depression and trait anxiety, and open ended questions related to health, religiosity, family, and social support. To examine age (young, middle age, and older adults), gender, and ethnicity differences in trait anxiety and depression, a MANOVA was conducted. The results revealed no significant gender and ethnic differences in trait anxiety and depression. There were no significant age differences in depression. When the younger group was excluded, the results were statistically significant F(1, 124) = 4.28, p = .04); older adults as opposed to middle aged adults reported significantly lower levels of depression (M = 17.05, SD = 11.58; M = 22.00, SD = 12.77 respectively). Significant age differences existed in trait anxiety F(2, 135) = 3.90, p = .02. Older adults in contrast to middle aged adults reported significantly lower scores on trait anxiety (M = 38.64, SD = 13.67; M = 45.44, SD = 13.01 respectively). In summary, of three age groups, older inmates scored lowest on trait anxiety and depression. This suggests that there are some underlying factors outside of ethnicity and gender, which contributed to the decreased levels of trait anxiety and depression.

## SUCCESSFUL AGING THROUGH THE EYES OF ALASKA NATIVES.' WHAT IT MEANS TO BE AN ELDER IN SOUTHWEST ALASKA

J. Lewis, *Alaska Native Studies, University of Alaska Fairbanks, Fairbanks, Alaska*

Alaska Natives view aging from a holistic perspective, an approach not typically found in the existing literature on successful aging. There is little research on Alaska Native (AN) Elders and how they subjectively define a successful older age. The lack of a culturally specific definition often results in the use of a generic definition that portrays AN Elders as aging less successfully than their non-Native counterparts. This research explores the concept of successful aging from an AN perspective and what it means to age well in AN communities. This study highlights four domains of successful aging, or “Eldership”: emotion, spirituality, community engagement, and physical health. One aspect of successful aging seen in each of these four domains is optimism, or having a positive outlook on life. These four domains serve as the foundation of how communities define who is an Elder and what is important when considering whether someone has aged successfully or not. Research findings also indicate that aging successfully is based on local understandings about personal responsibility and making the conscious decision to live a clean and healthy life. Most Elders stated that Elder status is not determined by reaching a certain age (e.g., 65 years), but instead is designated when an individual has demonstrated wisdom because of the experiences he or she has gained throughout life. This research seeks to inform future studies on rural aging that will prioritize the perspectives of Elders to impact positively on the delivery of health care services and programs in rural Alaska.

## GERIATRIC CONDITIONS IN OLDER HOMELESS ADULTS

R. Brown[1,2], M. Bharel[3,4], S. Mitchell[2,1], *1. Division of Gerontology, Beth Israel Deaconess Medical Center, Boston, Massachusetts, 2. Hebrew SeniorLife Institute for Aging Research, Roslindale, Massachusetts, 3. Boston Healthcare for the Homeless Program, Boston, Massachusetts, 4. Section of General Internal Medicine, Boston Medical Center, Boston, Massachusetts*

Background: The average age of the US homeless population is increasing. One-third of homeless adults are currently age 50 and older, increased from 11% in the early 1990s. The prevalence of geriatric syndromes in homeless adults age ≥50 has not been examined. Methods: Data were derived from an ongoing 12-month prospective cohort study of 250 homeless persons age ≥50 recruited from 6 large homeless shelters in Boston. This report describes demographics and geriatric syndromes from the first N=69 subjects recruited beginning January 25, 2010. Cognitive impairment was defined as MMSE ≤21, <23, or <24 (8th grade, high school, college education) or Trail Making Test Part B (TMT-B) >1.5 standard deviations (SDs) above population-based norms; hearing impairment as self-reported hearing impairment or inability to identify ≥50% of whispered stimuli in either ear; visual impairment as self-reported visual impairment or best-corrected vision <20/40 on Snellen chart; urinary incontinence as International Consultation on Incontinence Questionnaire score ≥1; and depression as PHQ-9 score ≥10. Results: The mean (SD) age of the sample was 56.5 (5.1) years. Six percent were women and 43% were African-American. Geriatric syndromes were common, including cognitive impairment (7.3% on MMSE (mean (SD) 27.1 (2.4)) and 69.7% on TMT-B (mean (SD) 144.7 (74.6)); hearing impairment (46.4%); visual impairment (52.2%); urinary incontinence (58%); and depression (46.4%). Conclusions: Potentially treatable geriatric syndromes are common in older homeless adults. Knowledge of the prevalence of geriatric syndromes is a necessary first step towards understanding the health problems facing this growing segment of underserved older Americans.

## SOCIOECONOMIC STATUS, PREVENTABLE DEATHS, AND THE LAUNCHING OF NATIONAL HEALTH INSURANCE IN TAIWAN

H. Tung, *Healthcare Administration, Asia University, Wufeng, Taichung, Taiwan*

Link and Phelan proposed a “fundamental causes” theory to explain the persistence of the association between socioeconomic status (SES) and health outcomes. People with higher SES status have better resources that can be used in different ways in different situations to avoid risks for disease and death, so that stronger SES gradients in mortality should be observed for causes of death that are highly preventable (effective measures of prevention or treatment are available) and weaker associations between SES and low-preventability causes of death. Adopting the methods developed by Phelan and her colleagues, we examined this theory with data from a longitudinal survey of elders in Taiwan. We also examined whether the launching of Taiwan’s National Health Insurance (NHI) in 1995 has contributed to narrowing the SES gradients in mortality. Survival status and causes of death were obtained from the Death Certificates managed by the Department of Health. SES status was measured as the elders’ educational attainment and income. Proportional hazard models were conducted for the before- (1989 through 1995) and after-NHI (1996 through 2003) follow-up periods. Results showed that, there were 549 high- and 190 low-preventability deaths during the before-NHI period. Stronger associations were observed between SES measures and mortality for high-preventability causes of death. For the after-NHI period, there were 816 high- and 297 low-preventability deaths. Again, stronger associations were seen between SES measures and high-preventability deaths. Plus, it seems the launching of NHI has played a limited role in narrowing SES gradients in mortality from the high-preventability causes.

## RACIAL AND ETHNIC DIFFERENCES IN SELF-RATED HEALTH IN LATE ADULTHOOD: A LONGITUDINAL ASSESSMENT

K. Kwag, Y. Jang, D.A. Chiriboga, *Aging and Mental Health Disparities, University of South Florida, Tampa, Florida*

The objective of this study was to examine racial and ethnic differences in the baseline level and change of trajectories in self-rated health (SRH) in late adulthood. The data for this study come from 5 waves of the Health and Retirement Study (N = 5,710 individuals aged 65 and older), univariate latent growth curves (LGCs) with the baseline level and change as latent constructs were estimated. The findings demonstrated that both Hispanic and Black older adults reported lower baseline levels but slower decrease of SRH than their non-Hispanic White counterparts, showing an equalization of SRH over time. In particular, White older adults reported faster decline in SRH but still maintained better SRH than racial and ethnic minority older adults. In comparing Hispanic and Black older adults, Hispanics reported the lower baseline level and faster decline than Blacks. Our findings support the existence of the racial and ethnic health disparities over time.

### ROLE OF SOCIAL CONTEXT IN AFRICAN AMERICAN HEALTH: EVIDENCE FROM CAATSA AND CENSUS ZIPCODE LEVEL DATA

F. Yong[1], K.E. Whitfield[2], *1. East Carlina University, Greenville, North Carolina, 2. Duke University, Durham, North Carolina*

Race-ethnicity is often the central feature in the discussions of health disparities, yet how these social constructs interact with different social contexts is less known. To address this issue, this pilot study examined the extent to which contextual factors explain mental and physical health, through traditionally studied individual factors. The contextual factors include both macro and mezzo level factors. Macro level factors include zipcode level socioeconomic characteristics (Zip-level-SES). They were extracted from Census 2000 summary file 3. Mezzo factors (family income, household structure, and social support), individual factors (blood pressure, digital span, life satisfaction, body mass index, age, education, and gender), and outcome variables (depression, self-rated health, the count of chronic illnesses) were from the Carolina African-American Twin Study of Aging (CAATSA). Zip-level-SES was combined with a data set from CAATSA (N=556; age range 22~88). The results show that depression ($p<.001$) and self-rated health ($p<.001$) are strongly explained by Zip-level-SES. The count of chronic illnesses ($p<.001$), by contrast, is explained by the individual factors. The unique findings are that the percentage of the white population living in a zipcode area is negatively associated with both depression ($p<.05$) and self-rated health ($p<.001$), and that family income ($p<.01$), rather than Zip-level-SES, is positively associated with all three outcome variables. These findings support "social stress models" and "social disorganization theory". We also highlight the importance of selecting a proper contextual level to explain individual health outcomes, suggesting that different contextual levels may have different influences on health.

## SESSION 140 (PAPER)

## EMOTIONAL REACTIVITY

### AGING AMPLIFIES THE EFFECT OF NEGATIVE AFFECT ON BEDTIME CORTISOL

J.R. Piazza[1], S.T. Charles[2], D. Almeida[1], R.S. Stawski[1], *1. Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania, 2. University of California, Irvine, Irvine, California*

The current study examined the association between negative affect (NA) and bedtime cortisol among people who participated in the National Study of Daily Experiences (NSDE), which is part of the Midlife Development in the United States (MIDUS) Survey. Participants (N = 2,022) completed a series of 8 consecutive nightly interviews, during which they reported the emotions they experienced over the course of the day. Of these participants, 86% provided 4 saliva samples (upon waking, 30 minutes after waking, before lunch and before bed) on 4 of the interview days. Trait and state NA were associated, such that on days people experienced higher levels of state NA, those who also scored high on trait NA had elevated bedtime cortisol levels. In addition, between-person analyses indicated that bedtime cortisol levels were elevated among people reporting higher levels of both state and trait NA. Both between- and within-person associations were most pronounced among older adults, demonstrating that NA may be more physiologically costly during later life. Findings will be discussed within the framework of the Theory of Strength and Vulnerability Integration (SAVI).

### EMOTIONAL & STRESS REACTIVITY IN DAILY LIFE ACROSS THE LIFESPAN

S. Scott, F. Blanchard-Fields, M. Sliwinski, *Georgia Institute of Technology, Atlanta, Georgia*

The link between the experience of stressors in daily life and emotional reactivity is of interest across the lifespan. This relationship may reflect two different effects: emotional reactivity (stress producing negative emotions) and stress reactivity (negative emotions predicting stress exposure or severity). Both types of reactivity were examined using lagged Multi-Level Models to predict subsequent stress from current negative affect and vice versa. Young, middle, and older adults (total N = 180) reported disruptive events and emotions 5 times daily in this 10 day time-sampling study. Across the study younger adults reported the highest levels of negative affect whereas stress severity was similar across age groups. Age differences in the results of emotional and stress reactivity analyses suggest middle aged adults may be particularly at-risk for lingering effects of disruptions and negative emotions. For the question of emotional reactivity, for middle aged adults reporting more severe disruptions predicted experience of negative emotions at the next survey that day; however, this lagged relationship between stress severity and later emotional reactions did not hold for neither younger or older adults. Examining the question of stress reactivity, previous level of negative affect was related to increased likelihood of reporting more severe disruptions at the next survey for middle aged adults. This relationship between negative affect and subsequent stress severity was weaker for older adults and not significant in young adults. Together, results indicate that the relationship between daily events and emotions is not necessarily unidirectional and varies across the lifespan.

### ARE INTRAINDIVIDUAL DIFFERENCES IN THE DYNAMICS OF NEGATIVE AFFECT AND STRESS CONSISTENT?

P.R. Deboeck[1], C.S. Bergeman[2], M.A. Montpetit[3], S.M. Boker[4], *1. Univeristy of Kansas, Lawrence, Kansas, 2. University of Notre Dame, Notre Dame, Indiana, 3. Illinoise Wesleyan University, Bloomington, Illinois, 4. University of Virginia, Charlottesville, Virginia*

With the collection of intensive individual measurements, novel information is being garnered about how older adults handle stressors in their daily lives. One individual characteristic that might be of particular importance is the extent to which changes in daily stress are related to, or produce, changes in negative affect. Of greater interest is the extent to which these relations are consistent over much of the lifespan or are particularly mutable as people adapt to their changing environments. This study examines a sample of over 300 older adults from the Notre Dame Study of Health and Well-being. As part of a larger study, older adults were asked to complete two series of 56-day measurements collected two years apart. These daily measurements include the Positive and Negative Affect Schedule (Watson, Clark, & Tellegen, 1988), and the Perceived Stress Scale (Cohen, Kamarck, & Mermelstein, 1983). Using latent differential equation modeling, a dynamical systems model is fit to the daily negative and stress self-reports. The model allows each individual to have his/her own parameters, and these parameters are estimated separately for each of the two years in which the daily measurements were collected. Correlations between the individual estimates of dynamical parameters are then examined. In particular, focus will be placed on the coupling between negative affect and stress. We will address whether over the course of two years, the individual estimates for the effect of negative affect on stress are highly correlated.

### DAILY SPIRITUAL EXPERIENCES: A BUFFER AGAINST THE EFFECT OF NEGATIVE LIFE EVENTS ON MOOD?

B. Jackson, C.S. Bergeman, *University of Notre Dame, Notre Dame, Indiana*

On the global level, spiritual experiences have been shown to buffer against the negative effects of life challenges on well-being, but global analyses do not necessarily capture the daily processes at work. The present project examined the daily associations between Negative Life Events (NLE), Daily Spiritual Experiences (DSE), and Mood (Positive and Negative Affect) within a stress-and-coping framework, especially focusing on the moderating effect of DSE on the deleterious impact of a given day's NLE on that day's Mood. A secondary question was whether between-person differences in global levels of Religious Practices, Religious Belief, and Spiritual Experiences impact these daily relationships. The sample consisted of 274 individuals from the later life cohort (> 60 years) of the Notre Dame Study of Health and Well-Being who completed both daily diaries (56 days) and global assessments in Year 3 of data collection. Multilevel modeling analyses tested both the within-person daily effects (Level 1) and the between-person global effects (Level 2). Results for Level 1 showed daily NLE to be positively related to NA and negatively related to PA, whereas DSE was positively associated with PA and negatively with NA; the daily interaction between NLE and DSE was significant for NA but not for PA. Results for Level 2 revealed that only global Religious Practices significantly predict the strength of the buffering effect for DSE on NA. These findings demonstrate the efficacy of daily spiritual experience as a coping mechanism in the face of stressors encountered in everyday life.

## SESSION 145 (SYMPOSIUM)

### FINANCIAL GERONTOLOGY: FROM RISK TOLERANCE TO CAPACITY AND VICTIMIZATION

Chair: *P.A. Lichtenberg, Wayne State University, Detroit, Michigan*
Discussant: *J.I. Wassel, University of North Carolina at Greensboro, Greensboro, North Carolina*

The links between aging, finances and health are becoming ever clearer, particularly with the recent economic downturn. Future older adults will be facing even more challenges to their economic security in the next few decades. Financial planner and gerontologist Mr. Donald Haas will present on research examining financial management across time by 400 individuals. These revealed improper and harmful management with misunderstanding of fundamental issues of risk tolerance and asset allocation. Drs. Karen Roberto and Peter Lichtenberg will present on different aspects of a growing phenomenon; financial victimization of older adults. Dr. Roberto will present data taken from national media coverage of financial issues of older adults. Dr. Lichtenberg will present from a national and two local urban data sets on prevalence of financial victimization and its correlates. Finally, Dr. Marson will present on issues of financial capacity and capacity assessment among those suffering from Parkinson's disease. Dr. Neal Cutler, one of the pioneers of creating the sub-field of financial gerontology will be the discussant. Thus from perspectives of financial planning to neuropsychology, aging and the media and health disparities this symposium is designed to bring together various aspects of financial gerontology. By bringing together research in the areas of financial management, capacity and victimization, this symposium should bring attention to the growing need to examine diverse financial issues in our expanding population of older adults.

### FINANCIAL SATISFACTION AND FINANCIAL VICTIMIZATION: PREVALENCE AND CORRELATES

P.A. Lichtenberg, *Wayne State University, Detroit, Michigan*

Financial victimization of older adults is increasing at an alarming rate. This presentation will focus on the prevalence of financial victimization and its demographic, health and financial correlates. Three samples were utilized; a nationally representative sample from the 2008 Psychosocial Questionnaire of the Health and Retirement Survey (n=7000), and two urban samples made up of largely African American older adults. Nationally, the prevalence of financial victimization across a 5-year period was 3.3%. This correlated with age (being in young old group), and with a measure of disability (increased victimization with higher rate of disability) as well as with financial satisfaction. The urban samples (n=555 and n=123) reported 3-4 times higher rates of victimization (10-12% prevalence rates), and the correlates were similar to the national sample with age and health as well as financial satisfaction being related to victimization.

### IMPAIRED FINANCIAL CAPACITY IN PARKINSON'S DISEASE PATIENTS WITH MILD COGNITIVE IMPAIRMENT AND DEMENTIA

D. Marson[1,2], R.C. Martin[1,2], K. Triebel[1,2], J. Hill[3], H. Griffith[1,2,3], A. Nicholas[1,2,4], R. Watts[1,2], N. Stover[1,2], *1. Department of Neurology, University of Alabama at Birmingham, Birmingham, Alabama, 2. Alzheimer's Disease Research Center, University of Alabama at Birmingham, Birmingham, Alabama, 3. Department of Psychology, University of Alabama at Birmingham, Birmingham, Alabama, 4. Veterans Administration Medical Center, Birmingham, Alabama*

Purpose: This study investigated the financial capacity of cognitively impaired patients with idiopathic Parkinson's disease (PD). Methods: Participants consisted of 20 older controls and 35 PD patients who met criteria for either mild cognitive impairment (PD-MCI, n=18) or PD dementia (PDD, n=17). Subjects completed a standardized performance measure of financial skills (Financial Capacity Instrument; FCI). Group performance scores, and individual capacity outcomes (capable, marginally capable, incapable), were identified for each FCI domain and for FCI total score. Results: Relative to controls, PD-MCI patients demonstrated impairment on FCI total score and FCI domains involving complex mental calculations (Basic Monetary Skills, Financial Concepts, and Investment Decisions). PDD patients demonstrated near global impairment on the FCI variables. Approximately 33% of PD-MCI patients and 80% of PDD patients were classified as either marginally capable or incapable on the FCI variables. Conclusion: Impairment of financial capacity is present in PD-MCI and is advanced/global in PDD.

### FINANCIAL ABUSE IN THE HEADLINES: PREVALENCE OF NATIONAL NEWSFEEDS

K.A. Roberto[1], P.B. Teaster[2], J. Migliaccio[3], R. Blancato[4], S. Lawrence[2], *1. Center for Gerontology, Virginia Tech, Blacksburg, Virginia, 2. University of Kentucky, Lexington, Kentucky, 3. MetLife Mature Market Institute, Westport, Connecticut, 4. Matz, Blancato & Associates, Inc., Washington, District of Columbia*

Financial elder abuse, the unauthorized use or illegal taking of funds or property of older adults, is under-recognized, under-reported, and under-prosecuted. We analyzed 266 media reports on financial abuse published from April-June 2008 to identify the type, extent, and implications of the abuse. Information extracted included characteristics of the victims and perpetrators, type, frequency, and location of abuse, amount stolen, and outcomes. Overall, the media reports revealed a total of approximately $396,654,700 in losses. Business and industry related financial abuse resulted in the highest losses to victims followed by Medicare/Medicaid fraud and that perpetrated by family, friends or strangers. However family members, friends, neighbors, and caregivers were most frequently involved as perpetrators of elder financial abuse followed by businesses of varying kinds and then strangers. Findings put a face on financial elder abuse and provided real-time information on a growing problem found in every community and among all social strata.

### THE CHANGING FINANCIAL NEEDS OF INDIVIDUALS AS THEY TRANSITION THROUGH THE DECADES OF THEIR LIVES

P.A. Lichtenberg, D. Haas, *Wayne State University, Detroit, Michigan*

Financial Gerontology is a relatively new discipline developed over the past 20 years, primarily by Neal E. Cutler, Ph.D. It is the study of financial aging over one's entire life. This longevity study of over 400 individuals, over periods of time ranging from 5 to 45 years, revealed improper and harmful financial management starting with misunderstood financial risk tolerance, asset allocation based on improper concepts, and investing based purely on age. The proper management of each component of financial aging needs understanding and periodic adjustments to reflect the changing resources, needs, and beliefs at each stage of life as well as understanding that the economics of an individual or a whole country is based on as few as one simple economic factor—consumerism, which controls 70%+ of an economy. As we consume more, the economy improves and visa-versa. Combine this with the demographics of the population, and one has a long-term insight to where the future economic trends will emerge and how long the economy will continue in that direction.

# SESSION 150 (POSTER)

## HEALTH CARE AND REHABILITATION

### COGNITION AND FUNCTIONAL RECOVERY IN OLDER ADULTS WITH HIP FRACTURE: IMPLICATIONS FOR LONG-TERM CARE

Y. Young, K. Xiong, R. Pruzek, *State University of New York at Albany, Rensselaer, New York*

Objective. To compare functional recovery patterns of cognitively impaired and non-impaired older adults who had hip fracture surgeries, and to identify associated long-term care needs. Methods. Longitudinal study (n=254). Data were collected within 72 hours of admission to and prior to discharge from the post-acute rehabilitation facilities and at 2-, 6-, and 12-months following post-acute rehabilitation discharge. Functional Independence Measures (FIM) was used to assess functional recovery. Mini-mental status examination (MMSE) was used to gauge cognitive function. Mixed-effects models were performed to compare differences of FIM functional recovery patterns between groups while adjusting for potential confounders. Results: Multivariate results indicate patients with impaired cognition had notably different functional recovery patterns and significantly worse overall FIM scores ($p<.001$) than their counterpart. For locomotion function at one year, following post-acute rehabilitation discharge, patients with intact cognition needed supervision (FIM mean = 5.6), while patients with impaired cognition needed 50% human assistance (FIM mean = 3.4). In addition to needing locomotion assistance, cognitively-impaired patients also required 25% human assistance in transfers (FIM mean = 4.55), 25% in self-care (FIM mean = 4.92), and 25% in sphincter control. Conclusion: Cognitively-impaired patients were not able to retain rehabilitation gains in locomotion, transfers, self-care, and sphincter control at one year following post-acute rehabilitation discharge, and they still required human assistance to stay in their homes within the community. To prevent or delay nursing home entry, appropriate long-term care planning and social support to caregivers are needed for cognitively-impaired hip fracture patients.

### PROXY AND CAREGIVING PREFERENCES IN ADVANCE CARE PLANNING: COMPARISONS ACROSS AGE, GENDER, AND SEXUAL ORIENTATION

A.K. Zaleta, B. Carpenter, *Psychology, Washington University, Saint Louis, Missouri*

Introduction. One component of advance care planning is choosing decisional proxies and caregivers for the future. In this study we examined how choices for proxies and caregivers differ across demographic groups. Methods. We surveyed 269 individuals, stratified by age, gender, and sexual orientation. Choosing from a list of family and friends, respondents rated who they would ideally like to make decisions for them in medical and financial matters, and who they would want to provide daily care to them in the future. Results. Overall, for decisional proxies and caregiving, spouses/partners were consistently ranked highest, followed by parents and children, then siblings, and finally, friends. Multivariate analyses of variance revealed that some rankings varied based on age and sexual orientation. Spouses/partners were most highly ranked across all groups, but differences were found in the remaining rankings. Younger adults, regardless of sexual orientation, identified parents as their second choice for proxies and caregivers. Friends were ranked as the second choice for caregiving by middle aged and older but not younger homosexuals. In contrast, heterosexual participants consistently ranked children over friends regardless of age; in fact, friends were ranked as the least preferred by heterosexuals. Summary. Spouses/partners were universally identified as the first choice for decisional proxies and caregivers. However, spouses/partners may not always be available to fulfill this role. Rankings of nonpartner proxies/caregivers varied by age and sexual orientation, suggesting that no one “rule of thumb” is sufficient to determine order of preference for proxies and caregivers.

### UNDERSTANDING DISCREPANCY IN VALUES BETWEEN CAREGIVERS AND INDIVIDUALS WITH MILD DEMENTIA

A.M. Reamy[1], K. Kim[1], S.H. Zarit[1], C.J. Whitlatch[2], *1. Human Development and Family Studies, The Pennsylvania State University, State College, Pennsylvania, 2. The Benjamin Rose Institute, Cleveland, Ohio*

Individuals with dementia (IWDs), whose symptoms are mild, are able to discuss their values and preferences for prospective care. Prior research suggests that discrepancies exist between the care values held by IWDs and what caregivers perceive these preferences to be. Using a sample of 266 dyads, where one person has early, mild dementia and the other is providing assistance and supervision, we considered the degree of agreement within the dyad and sources of disagreement for 5 types of values related to care. Using multilevel models, we found that caregivers and IWDs differed systematically on reports of values, with caregivers underestimating the IWD’s values on all five value categories considered (autonomy, burden, control, family, and safety). Race and cognitive functioning of the IWD were associated with the discrepancy of reported values. Discrepancies were further associated with the extent to which caregivers believed the IWD had involvement in care decisions and how much the caregiver took into account the IWD’s best interests when making care decisions. The results suggest that many caregivers do not have an accurate depiction of the IWD’s values. These findings indicate a need to investigate further both the predictors and the outcomes of such divergence to understand better the relationship between caregivers and people with early-stage dementia, and to inform intervention for this vulnerable subset of elder individuals.

### THE IMPORTANCE OF PROVIDER-CLIENT RACIAL CONCORDANCE IN THE HEALTHCARE ARENA: THE CLIENT PERSPECTIVE

W.J. Puentes, *School of Nursing, University of Medicine & Dentistry of New Jersey, Stratford, New Jersey*

It has been suggested that healthcare provider-consumer racial, ethnic and language concordance is linked to with higher patient satisfaction and better health care processes. The investigator explored this issue in follow-up interviews of a pilot study designed to test the efficacy of a psychosocial anxiety management intervention for individuals diagnosed with early Alzheimer’s disease. The intervention was based on the use of reminiscence. The investigator, who is white, asked the study participants and their caregivers (N=10), who were African-American, to describe their impressions and feelings regarding the interaction between themselves and the investigator. Subjects and their caregivers reported that having a white investigator coming into their homes in exclusively African-American urban communities initially was viewed with suspicion. As they began to tell their stories and engage with the investigator, they reported that issues related to racial discordance were no longer as important and that the empathy and interest exhibited by the investigator was a more significant influence on the interpersonal interaction. Several subjects reported that they were more comfortable interacting with the investigator than with their African-American caregivers in other settings. This was due to the dynamic of other caregivers assuming they understood the subjects' healthcare and personal needs because of racial concordance while the investigator took the time to understand their lived experience. Implications of these findings for clinical practice and future research are discussed.

### NURSES' PERCEPTIONS AND EXPERIENCES AT DAYCARE FOR ELDERLY WITH STROKE

Y. Park, *Nursing, Seoul National University, Seoul, Republic of Korea*

Purpose: While adult daycare (ADC) is considered a culturally acceptable model of long-term care in countries with a tradition of family-oriented caregiving, Korea is struggling as soaring needs for ADC outpace qualified staff and regulatory systems. This study aimed to describe Korean daycare nurses' perceptions of key daycare services and their working experiences with stroke patients and their families. Design: A mixed-method design was used. First, we conducted a cross-sectional descriptive survey to assess Korean nurses' perceptions about the importance of daycare services. Then focus group interviews were performed to explore the nurses' experiences at ADC. Methods: Seventy out of a total of 96 nurses at ADC specialized in the care of stroke patients responded the survey (response rate=72.9%) and rated the importance of 11 key daycare service items on a visual analogue scale (0-10). Using a purposive sampling design, 16 eligible nurses were interviewed as a group. The qualitative data from focus group interviews were analyzed using thematic analysis to classify common themes into larger categories. Findings: Survey data revealed that the nurses perceived 'skilled nursing services,' 'functional recovery,' and 'general health counseling' as the most important daycare service areas. Focus group data resulted in five themes: 'Providing the same, standard care,' 'Lack of partnership with family caregivers,' 'Conflict with other staff: ambiguity of the roles and tasks,' 'Lack of proper education and training,' and 'Need for quality control and monitoring.' Conclusions: Daycare nurses fully recognized the importance of direct nursing care services that are keys to adequate recovery and rehabilitation of older patients with stroke. However, they experienced substantial barriers to carrying out these services due to role confusion, insufficient number of qualified nursing staff, and lack of partnership with family caregivers. Clinical relevance: The results provide insight into changing health care policy to support daycare nurses in a country with limited resources and regulations. Strategies such as better quality control and monitoring of daycare services, provision of continuing education, and prioritizing key services should be considered as a way to address challenges experienced by daycare nurses.

### THE RELATIONSHIP OF MEDICATION TO LIFESTYLE TREATMENT ADHERENCE FACTORS IN HYPERTENSIVE PATIENTS

A.B. Berkowitz, L. Phillips, H. Leventhal, E.A. Leventhal, *Institute for Health, Health Care Policy, and Aging Research. Center for the Study of Health Beliefs and Behaviors., Rutgers University, New Brunswick, New Jersey*

The present study assessed if the factors involved in medication and lifestyle (diet, exercise, other) adherence are distinct from each other in a sample of hypertensive patients. Measures based off of the commonsense model of illness representations were used to determine the theoretical factors that are similarly/differentially important for medication compared to lifestyle-treatment adherence. Primary care patients (n = 105) with hypertension answered these items and others known to predict one type of adherence or the other, along with validated self-report measures of adherence. The predictive power of the items for each type of adherence (medication versus lifestyle-treatment) was assessed with correlations and regression. Medication and lifestyle-treatment adherence had zero correlation to each other, supporting the hypothesis that they are distinct constructs. Furthermore, the predictors of medication adherence (e.g., management of side-effects and treatment-related worry) were distinct from the predictors of lifestyle-treatment adherence (e.g., self-assessed health and illness-related worry).

### REGIONAL VARIATION IN RATES OF PREVENTABLE HOSPITALIZATION AMONG OLDER ADULTS IN BARBADOS

J. Bushelle-Edghill, J.N. Laditka, B.F. Ekezue, *College of Health and Human Services, University of North Carolina at Charlotte, Charlotte, North Carolina*

Hospitalization for ambulatory care sensitive conditions (ACSH), sometimes called potentially preventable hospitalization, has been used extensively to indicate access to primary health care of reasonable quality. Barbados is a developing nation with a comprehensive health care system that should enable access and produce relatively low rates of ACSH. No study has examined ACSH in Barbados. We calculated the ACSH rate for individuals ages 50+, and regional ACSH variation. Using 2002-2008 data (n=76,573) from Barbados, we investigated the five most common ACSH diagnoses, and rates of these hospitalizations for Barbados' 11 parishes. Of the Barbadian population ages 50+, 9.5% had ACSH admissions, accounting for 33% of all hospitalizations. The five most common diagnoses were diabetes & related amputations (8.4%), asthma (6.2%), hypertension (5.9%), CHF (5.1%), and urinary tract infection (5.0%). Men had higher rates, 99.34 per 1,000 population, than women, 90.4 ($p<0.0001$). Across the parishes, the rate of ACSH was highest for St. Michael (116.7 per 1000 population), St. Joseph (101.1), and St. John (98.8), with St. Peter, St. George and St. Thomas parishes having similar rates (94.0). Although Barbados has a comprehensive health care system, significant regional variation exists in ASCH rates among older adults, and a substantial proportion of hospitalizations are ACSH. This result suggests a notable opportunity for enhanced primary health care and cost savings. It will be useful for research to evaluate how the regional distribution of health care resources affects accessibility and quality of primary health care, and consequently ACSH.

### COGNITIVE STRATEGIES AND CARES TOWARDS ELDERLY WITH FUNCTIONAL INCONTINENCE AFTER BRAIN INJURY

M. Nagashima[1], C. Seki[1], A. Katada[2], *1. Tsukuba International University, Tsuchiura-shi, Ibaraki-ken, Japan, 2. Thubu Gakuin University, Seki-shi, Gifu-ken, Japan*

Purpose: To clarify cognitive strategies and common cares towards 20 elderly post brain injury patients whose functional incontinence disappeared after administrating Incontinence Care Programs (ICPs). Methods: Participants were 17 men and 3 women with normal bladder functions. Their average age was 66.4 (SD 4.9) years old, 70% of them were diagnosed cerebral infarction, 70% of them had left paralysis, and they had multiple and higher cortical dysfunctions. Subjective data was cognitive strategies after administrating ICPs for the participants and common characteristics of cares done by primary nurses considering the age of participants. Results: Fourteen participants eliminated their functional incontinence, 5 improved, one had no changes and no one had marked deterioration. Three major cognitive strategies were extracted: control for information input, control for learning methods, control for reactions and enforcements. There were 5 categories in the control for information input: selecting methods for caution, adjusting amount and simplify information, selecting communication symbols, adjusting shape, color and types of information, and information to guide movements. There were 3 categories in the control for learning methods: adjusting practice orders, cues for urinating environments and for movements. There were 2 categories in the control for reactions and enforcements: admiration and selection of cost/token. Common cares done by primary nurses toward aged participants were fall prevention because of weakened muscle strength and depression because of lowered self-esteem. Conclusion: It was suggested that ICP s were effective for elderly patients with functional incontinence and normal bladder functions.

### A COMPARISON OF ANIMAL-ASSISTED THERAPY AND ANIMAL-ASSISTED ACTIVITIES WITH DOGS IN SWEDISH RESIDENTIAL CARE

C. Nord*, Linköping university, Norrköping, Sweden*

This Poster Aims at Comparing Goal-oriented Rehabilitation Work with Dogs and Activities with Dogs Performed Without Explicit Therapeutic Goals. It is a Qualitative Research Project Based on Interviews with and Observations of Staff, as Well as Older People. The Results Presented Comes from an Evaluation of Two Assisted Living Facilities in Which Animal Assisted Therapy Had Been Used for Three Years. This Programme (AAT) Was Carried out with Trained Dogs on the Basis of Referrals Made by Occupational Therapists, Nurses, Medical Doctors and Physiotherapists. This Rehabilitative Work Was Compared to Situations in Assisted Living Facilities Where Dogs Were Used Primarily for Socialising Purposes (AAA). Preliminary Results Show That the Two Ways of Using Dogs Were Very Different in Certain Respects, Especially as to Their Therapeutic Ambitions, Even Though They Overlapped. The Variety of AAA Was Great. Ownership and Keeping of the Dog Varied. The Presence of Goals Also Varied. The Use of the Dogs Often Had a More or Less Explicit Aim to Increase Well-being and Social Skills Among the Residents. This Goal Made It Similar to the AAT Programme. Older People Who Encountered the Trained Dog in the AAT Programme Never Realized That They Were Actually Participating in a Rehabilitation Programme but Thought That the Purpose Was Amusement Alone. The Idea Was That the Older Person Would Participate More Voluntarily Because They Enjoyed Themselves. Preliminary Conclusions Are That the Range of Exercises with Dogs Has Great Potential and That AAA and AAT Can Be Mixed in New Fruitful Combinations.

### CONTENTS OF NIGHTSTANDS AMONG PATIENTS AT A REHABILITATION HOSPITAL

J. Brooks[1,2], S. Healy[2], M. Argoe[1], L. Smolentzov[1], A. Reis[2], I. Walker[1], K.E. Green[1], *1. Clemson University, Clemson, South Carolina, 2. Greenville Hospital System University Medical Center, Greenville, South Carolina*

Furniture available to patients in rehabilitation settings is limited. Typically, furniture utilized by the patients consists of the bed, the over-the-bed table and the nightstand. To begin to improve furniture design, this study sought to evaluate the contents of the over-the-bed table and nightstand for cognizant, functional patients in an inpatient rehabilitation setting. Locations, numbers and types of objects were recorded for 36 patients (18 males) with a mean age of 63.7 years (SD = 16.7 years). Patients in both private rooms (N = 21) and semi-private rooms (N = 15) participated. The patients' mean length of stay was 7.8 days with a maximum of 23 days. Over 750 individual items were recorded and grouped into 22 categories. The four most frequent categories were personal hygiene, food accessory, telephone, and water pitcher. Most items were located on the over-the-bed table followed by the top of the nightstand. Very few items were located in the nightstand drawers. If the drawers were used, it was typically only the top drawer. It appears that nightstand drawers may be functionally inaccessible for rehabilitation patients. New furniture designs may be able to increase patient independence and satisfaction.

### A PROFILE OF DIRECT CARE WORKERS FROM THE AMERICAN COMMUNITY SURVEY: CHANGES FROM 2000 THROUGH 2008

J. Deichert, K. Kosloski, L. Holley, *University of Nebraska at Omaha, Omaha, Nebraska*

The federal program for systems change encourages states to provide supports for chronically impaired older adults who wish to remain in the community rather than be institutionalized (Folkemer & Coleman, 2006). This movement has put increasing pressure on the supply of home care workers, where serious shortages already exist (U.S. DHHS, 2003). The goal of this study was to track changes in the population of direct care workers particularly home care workers that could affect supply, performance, and provide insights into potential recruitment and retention strategies of these individuals. Data were analyzed for eight waves of the American Community Survey (ACS), along with comparison data from the 2000 decennial census. The findings indicate that there have been substantial percentage increases in hospital aides (17.5%), and nursing home aides (26.3%); but the largest increase has occurred with home care aides (60.8%). Moreover, in 2000, the proportion of credentialed home care workers relative to uncredentialed workers approached 2 to 1. By 2008, the number of uncredentialed home care workers actually exceeded those credentialed, making them the second largest group of direct care workers. There also have been important changes in the characteristics of the home care workforce. For example, it is becoming more of a full-time workforce. Additionally, the proportion of home care workers for whom English is a second language and who are Hispanic continues to increase. Interestingly, the proportion of self-employed home care workers has been continually decreasing. Overall, these findings document the increasing importance of the home care workforce.

### WHAT PRECIPITATES ADMISSION TO SUBACUTE CARE?: DIAGNOSTIC VS. SUBJECTIVE REPORTS FROM PATIENTS

J.Y. Rodriguez, A. Horowitz, J.P. Reinhardt, K. Boerner, *Jewish Home Lifecare, NY, New York*

Admission to subacute units within long-term care facilities are typically precipitated by medical/rehab needs, but can be influenced by other life events as well. In this study, we compared the primary admitting medical diagnosis with the elder's self-reported life events prior to admission. A sample of 68 elders were interviewed within two weeks of their admission and data were also collected from medical records. Subjects had a mean age of 77, were predominately female (72%), White (67%), and lived in their own apartment/home before admission (93%). All patients reported some type of medical condition related to their admission. Also, 32% of the patients reported a major life event that was not medically related. Frequent medical conditions reported by the patients included surgical procedures (29%), falls (28%), cancer (15%) and stroke (10%). Concurrent reported life experiences included general physical decline (18%), death in support system (11%), aging (5%), and problems with housing (5%). About two-thirds (69%) of the patients self-reported a medical condition that corresponded and overlapped with the medical diagnosis from the medical record. Discrepancies included dissimilar accounts of medical conditions, such as pneumonia and surgery; meningitis and a seizure. While most patients focused on their current medical condition as their reason for admission into subacute rehabilitation, some of the more complex life experiences reported may also affect the recovery of some patients. Identifying and accounting for the medical and non-medical life experiences of subacute patients may be useful in developing a comprehensive care plan to assist with recovery.

## SESSION 155 (SYMPOSIUM)

### HEALTH DISPARITIES OVER THE LIFE COURSE

Chair: *E.K. Bozzelli, Miami University, Oxford, Ohio*

Whereas the life expectancy of the American population has continuously increased, health inequality has actually widened across different socio-demographic/economic groups. Addressing such existing health disparities is a public health priority of Healthy People 2010. Cumulative inequality (CI) theory holds that individuals who are in disadvantageous positions face greater health risks while those with advantage have more opportunities to improve/maintain health over the life course. Thus, studying the accumulation of inequality throughout the aging process and later life differences is of great interest. This symposium explores health disparities in light of CI theory and the Third Age. First, Shippee, Rinaldo, and Ferraro employ National Longitudinal Survey of Mature Women (NLSMW) data from 1967 to 2003 in discovering how perceptions of SES affect women's self-rated health throughout the life course. Second, Yamashita examines the disproportionate prevalence of type 2 diabetes across SES using nationally representative Behavioral Risk Factor Surveillance System (BRFSS) 2005 data. Third, Carr, Brown, and Lynch calculate how differences in the Third Age life expectancy vary in relation to SES, race, and gender based on National Health Interview Survey (NHIS) data, also from 2005. Finally, the Chair/Discussant will highlight each study's implications for future research and practice that are useful in addressing health inequality in the U.S. Taken together, these papers express how health disparities are experienced in different ways according to social context, education, resources (e.g., human agency), and genetic make-up.

### HEALTH CONSEQUENCES OF WOMEN'S SOCIOECONOMIC STATUS OVER THREE DECADES: TESTING CUMULATIVE INEQUALITY THEORY

T.P. Shippee, L.A. Rinaldo, K. Ferraro, *Purdue University, West Lafayette, Indiana*

Objectives: Drawing on cumulative inequality theory, this research examines how perceptions of socioeconomic status affect women's self-rated health over the life course. Particular emphasis is given to differences in the trajectories of Black and White women. Methods: Using data from the National Longitudinal Survey of Mature Women, we employ growth curve models to examine whether satisfaction with income influences women's health beyond objective measures of income, job type, and occupational prestige. Results: Satisfaction with income significantly predicts women's health over the life course, beyond the effects of objective measures of socioeconomic status. Effects differ by race: among White women, only satisfaction with income significantly predicts health; for Black women, both income satisfaction and objective measures have significant effects, but satisfaction remains a stronger predictor of health. Discussion: Findings indicate the importance of accounting for both perceived and objective trajectories in predicting health, and provide support for cumulative inequality theory.

### SOCIO-ECONOMIC DISPARITIES IN TYPE 2 DIABETES PREVALENCE AND DISEASE MANAGEMENT OUTCOMES IN OLDER POPULATIONS

T. Yamashita, *Miami University, Oxford, Ohio*

Whereas overwhelming evidence shows that socio-economic status (SES) predicts a variety of health outcomes, less is known about possible etiological explanations for pathways between SES and diabetes prevalence/management outcomes. Given the high prevalence of type 2 diabetes in older populations (23.1% in 2007) and challenging nature of management regimens, analyzing individuals with diabetes may provide useful insights for better understanding the possible mechanism of health disparities over the life course. This study examines older adults with type 2 diabetes in light of cumulative inequality theory using nationally representative BRFSS 2005 data. In accordance with a series of quantitative analyses, theoretical explanations (e.g., practical skills in diabetes management, community living environment) are evaluated. The presentation concludes with recommendations for future health disparity research, including suggestions for how SES measures can be refined.

### INEQUALITY IN THE THIRD AGE

D.C. Carr[1], J. Brown[2], S.M. Lynch[3], *1. Scripps Gerontology Center, Oxford, Ohio, 2. Miami University, Oxford, Ohio, 3. Princeton University, Princeton, New Jersey*

The emergence of the third age, a period occurring after retirement but prior to the onset of disability, has been described as a period of privilege whereby some individuals more than others are able to engage actively in society during later life. Although the average individual within the United States can expect to experience a third age, the amount of time one can expect to spend in this period varies. To more adequately understand inequalities related to the "active potential" of later life, this project uses life table analyses to calculate and examine differences in third age life expectancy (TALE) for individuals based on socioeconomic status, race and gender. We use the NHIS and vital statistics data and utilize a new Bayesian approach to life table construction that allows for the inclusion of survey-based covariates, a capability absent from traditional cross-sectional life table methods. Implications for theory and policy are discussed.

## SESSION 160 (PAPER)

## HISPANIC CAREGIVING

### EVALUATION OF A CULTURALLY APPROPRIATE, SPANISH LANGUAGE PROGRAM FOR CAREGIVERS OF PERSONS WITH ALZHEIMER'S DISEASE OR RELATED DEMENTIA

M. Talamantes[1,2], C.L. Alford[2], S. Oakes[2], *1. Our Lady of the Lake University, San Antonio, Texas, 2. University of Texas Health Science Center, San Antonio, Texas*

Cuidando con Respeto is a culturally appropriate, Spanish language, psychoeducational program for caregivers of family members with Alzheimer's disease or related dementia. This eight hour program, delivered in two sessions, is based on the Savvy Caregiver Program (Hepburn, Lewis, Sherman, & Tornatore, 2003). In adapting the course for a Spanish speaking population, our goal was to make the course culturally, linguistically, and educationally appropriate for Spanish speaking families. After successfully piloting the program (Oakes, Hepburn, Ross, Talamantes, & Espino, 2006), we planned and implemented a training process to prepare new course presenters with an emphasis on maintaining fidelity. These newly prepared trainers then presented the course twenty times to 294 caregivers over a period of eight months in the state of California. This paper reports on the dissemination process and a multi-faceted evaluation of the program. The course evaluation and open-ended telephone interviews conducted three to six months after the end of the course produced the strongest evaluation evidence, leading to the conclusion that the program was successful in teaching caregivers attitudes, knowledge, and skills that led to changes in caregiving practices.

### THE EFFECT OF ACCULTURATION AND MUTUALITY ON FAMILY LOYALTY AMONG MEXICAN AMERICAN FAMILY CAREGIVERS OF OLDER ADULTS

H.S. Kao[1], M.L. Lynn[2], *1. School of Nusing, The University of Texas at El Paso, El Paso, Texas, 2. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

This study explores the relationships among cultural orientation, mutuality, and the expectations of family loyalty for Mexican American (MA) adult children in caregiving relationships with elderly relatives. Using Confirmatory Factor Analysis, data from a convenient sample of 192 MA adult family caregivers of community-dwelling older adults in El Paso, TX were analyzed. Cultural orientation was found to have minimal effect on family loyalty and no significant effect on mutuality. However, mutuality and family loyalty were found to have a strong relationship. The overall model was supported by the data. These findings provide a greater understanding of the proposed model for the expectations of family loyalty toward elderly relatives in the MA culture. While caregivers with a higher Mexican orientation tend to present higher expectations of family loyalty toward their elderly relatives than their Anglo orientation counterparts, it is mutuality, especially the interactions between the caregiving dyad (B = .09), which exhibits the most substantial effect on family loyalty. It thus appears that mutual exchanges between the caregiving dyad are better predictors of filial obligation than the caregivers' cultural orientation. In give-and-take family relationships, 'you reap what you sow' appears to be an idea that should be incorporated into research with Mexican American families. In addition to respecting traditional family mores, family care interventions for older adults in this population may well need to start with an understanding of the motivations that shape everyday caregiving activities.

### POSITIVE FEELINGS OF CAREGIVING AMONG LATINO ALZHEIMER'S FAMILY CAREGIVERS: THE ROLE OF SPIRITUALITY AND RELIGION

F. Sun, D. Hodge, *School of Social Work, ASU, Phoenix, Arizona*

Purpose: In light of the growing size and cultural distinctiveness of the Latino population, this study examined the role of spirituality and religion in relation to caregiving stressors and caregiving outcomes [i.e., positive aspects of caregiving (PAC)] among a sample of Latino Alzheimer's family caregivers. Methods: The study was conducted using baseline Latino participants (N=209) from the NIH-funded Resources for Enhancing Alzheimer's Caregiver Health II dataset. The sample (Mage=58, SD=13.7) was 82.3% female and 34.6% Cuban American, 21.6% Mexican heritage, 21.2 % Puerto Rican, and 22.5% other Latino. Guided by Pearlin and associate's model, we assessed objective stressors (e.g., care recipient ADL/IADL difficulties), subjective stressors (e.g., caregiver burden), and PAC. Spirituality/religion was indicated by frequency of prayer, church attendance, and religious coping. Covariates included caregiver socioeconomic status (SES), social support, years in the U.S., and caregiver country of origin. Results: To test the model, structural equation modeling (SEM) was used. A good model fit was achieved (CFI=.93, SRMR=.07, RMSEA=.06). The results suggest Cuban caregivers were less likely to engage in spirituality/religion than other Latino caregivers; participants with higher levels of spirituality/religion tended to have higher PAC; social support was positively related to PAC, while SES was inversely related to PAC. Implications: PAC is a salient construct among Latino caregivers. Facilitating spiritual/religious engagement and social support may help increase levels of PAC among Latino caregivers.

### DOES FAMILISM BUFFER OR EXACERBATE THE NEGATIVE IMPACT OF FAMILY CONFLICT ON HISPANIC CAREGIVERS?

S.S. Koerner, Y. Shirai, R. Pedroza, *Family Studies and Human Dev., University of Arizona, Tucson, Arizona*

Research repeatedly highlights the importance of family when Hispanic older adults are in need of care. Indeed, Hispanic family caregivers (HCs) hold stronger familism beliefs than their non-Hispanic White counterparts, are less likely to use professional services, and are more likely to share responsibilities with other family members. Despite the salient role of family in the Hispanic caregiving experience, no research studies have investigated the impact of family conflict/disagreement regarding care on the well-being of HCs. The current study used a daily diary design to examine: (a) the impact of family disagreement regarding care on the daily emotional/physical reactivity of HCs, and (b) the moderating role of familism - whether strong familism beliefs buffer or exacerbate the negative impact of family disagreement regarding care on the well-being of HCs. HCs of Mexican descent (N=67), reported their daily experiences (family disagreements regarding care, depressive symptoms, feelings of burden, physical health symptoms) on 8 survey days, and completed one familism scale (Sabogal et al., 1987). Multilevel modeling indicated that, on days when these HCs reported more than their usual number of family disagreements regarding care, they experienced decreases in well-being. Significant moderator effects indicated that the latter association was especially apparent for caregivers who strongly endorsed familism beliefs. Specifically, the experience of an additional family disagreement regarding care was more strongly associated with increased depressive symptoms (gamma11=.387, p<.01) and feelings of burden (gamma11=.167, p<.05) for HCs with stronger familism beliefs. Implications for further research and intervention will be discussed.

## SESSION 165 (SYMPOSIUM)

### NEIGHBORHOODS AND HEALTH: PUSHING THE BOUNDARIES

Chair: *R.A. Pruchno, New Jersey Institute for Successful Aging, University of Medicine & Dentistry School of Osteopathic Medicine, Stratford, New Jersey*
Discussant: *M.C. Fahs, Hunter College, New York, New York*

While there has been a surge of research devoted to examining the effects of neighborhood characteristics on the physical and mental health of older adults, most of these efforts have operationalized neighborhoods according to socioeconomic status, using rates of poverty, economic deprivation, and education as indicators. Yet there are a host of additional components of neighborhoods, including social vulnerability, wealth, violence, density, residential stability, the presence of physicians, supermarkets, bars and fast food establishments that may explain the mechanisms by which neighborhoods affect health. There are also questions about what constitutes a neighborhood and whether administratively defined geographic boundaries are meaningful to people. Operationalizing health from diverse perspectives that include physical activity, self-reported health, and depression, presentations examine the relationship between neighborhoods and health. Presenters describe how neighborhoods are defined by the older people who live in them and question whether these definitions compare with actual geographic boundaries. They examine the influences of perceived as well as objective characteristics of neighborhoods, using data from diverse sources that include administrative databases, GIS, and self-report. Using a combination of qualitative and quantitative analyses presentations demonstrate how neighborhood characteristics influence health. Discussion centers on the importance of examining multidimensional aspects of neighborhood and health as well as identifying the boundaries of neighborhoods.

### HOW NEIGHBORHOOD INFLUENCES HEALTH: UNRAVELING COMPLEX RELATIONSHIPS

R.A. Pruchno[1], M. Wilson-Genderson[2], F.P. Cartwright[1], *1. New Jersey Institute for Successful Aging, University of Medicine & Dentistry School of Osteopathic Medicine, Stratford, New Jersey, 2. Virginia Commonwealth University, Richmond, Virginia*

Although the effects of neighborhoods on self-rated health and depression are known, the mechanisms by which neighborhoods influence health are unclear. Using data from 5,688 persons aged 50-74 living in New Jersey we examine how characteristics of neighborhoods, including social vulnerability, wealth, violence, density, stability, and the presence of physicians, bars supermarkets, and fast food establishments influence health and depression. Hierarchical linear modeling analyses, controlling for gender, age, marital status, race, education, and income finds that indicators of violence, density, and social vulnerability influence self-rated health, while effects on depression are limited to neighborhood density and violence. Discussion centers on the different relationships that multiple facets of neighborhoods have on health.

### THE TEXTURE OF NEIGHBORHOODS: A CONCEPTUAL AND EMPIRICAL MODEL

R.A. Pruchno[1], M. Wilson-Genderson[2,1], F.P. Cartwright[1], *1. New Jersey Institute for Successful Aging, University of Medicine & Dentistry School of Osteopathic Medicine, Stratford, New Jersey, 2. Virginia Commonwealth University, Richmond, Virginia*

A multidimensional conceptual model of neighborhood characteristics likely to influence health, including social vulnerability, wealth, violence, density, stability, and the presence of physicians, bars, supermarkets, and fast food establishments is presented. Using administrative data representing 1,644 of New Jersey's census tracts from the 2000 U.S. Census, 2006 New Jersey Uniform Crime Report, New Jersey Department of Agriculture's Division of Marketing and Development, and New Jersey's Department of Law and Public Safety's Division of Alcohol Beverage Control the robustness of the model is demonstrated. Fit statistics of the final model ($\chi 2 = 418.73$, df = 113, NFI = 0.96, TLI = 0.96, CFI = 0.97, RMSEA =0.06, Hoelter = 296) suggest that the model is an excellent representation. The authors highlight the importance of using multiple indicators of neighborhood with good psychometric qualities for advancing knowledge about the mechanisms by which neighborhoods influence health.

### NEIGHBORHOOD CONTEXT: A COMPARISON OF CENSUS BOUNDARIES AND INDIVIDUAL PERCEPTIONS

I. Yen[1], E. Kersten[2], J. Connors[2], *1. University of California, San Francisco, San Francisco, California, 2. University of California, Berkeley, Berkeley, California*

The vast majority of research on the influence of neighborhood environment on health behaviors and health has defined neighborhood by census tract or block group boundaries, but these may not accurately represent an individual's neighborhood context. We asked 58 older adults (ages 62 to 85) who live in the San Francisco Bay Area to hand-draw the boundaries of their neighborhoods. These boundaries were digitized using Google Earth free software then imported into Geographic Information System (GIS) software to calculate the areas. There was a wide range of neighborhood areas from 0.007 to 8 square miles. Men, people who owned their homes, and people with higher educational attainment drew larger neighborhoods than women, people who rented, and people with lower education. There was no difference in area by age or perceived health status. The differences in perceived size of neighborhood may have implications for access to services and resources.

### PROMOTING ACTIVE URBAN AGING: CREATING A COMBINED WALKABILITY INDEX FOR OLDER ADULTS USING A GEOGRAPHIC INFORMATION SYSTEM

R.C. Weiss[2,1], M.C. Fahs[1,2], J.A. Maantay[3], *1. Brookdale Center for Healthy Aging & Longevity of Hunter College, New York, New York, 2. Doctoral Program in Public Health, City University of New York Graduate Center and CUNY School of Public Health, New York, New York, 3. Urban GISc. Lab, Lehman College/CUNY, New York, New York*

Conflicting evidence on the association between perceived and objectively measured walkability and physical activity among urban-dwelling older adults suggests both actual neighborhood environmental features and perceptions influence walking behavior. This project creates a Combined Walkability Index (CWI) using a Geographic Information System (GIS) incorporating data from an objective data audit and a subjective survey. Computerized Neighborhood Environment Tracking (ComNET) was used to systematically assess environmental risks impacting activity patterns of older adults in two NYC neighborhoods. In addition, the Senior Center Evaluation of the Neighborhood Environment (SCENE) survey was administered to 103 older adults attending two senior centers located within the target neighborhoods. Results indicate substantial variation in walkability and perceptions, with twice as many trip hazards (104 vs 269, $p<.05$) in the low vs high income neighborhood. GIS can contribute to creating active communities through data integration methods that recognize complex relationships between the built environment and neighborhood perceptions relevant to physical activity behavior.

## SESSION 170 (SYMPOSIUM)

### REPARTNERING IN LATER LIFE: THE PURSUIT OF NEW RELATIONSHIPS, LIVING APART TOGETHER AND REMARRIAGE

Chair: *D. Brothers, Miami University, Oxford, Ohio*
Discussant: *J. Gierveld, Netherlands Interdisciplinary Demographic Institute, The Hague, Netherlands*

Demographic and socio-cultural changes in Western societies have altered and continue to alter the ways in which people are partnering across the life course, including later life. The unprecedented number of older adults who are facing increasing longevity and who have been exposed to more varied partnering practices over their lifetimes (e.g., increasing rates of divorce, cohabiting, remarrying, remaining single, etc.) are pursuing and finding new relationships in later life. Despite the fact that partnering practices are becoming more diverse and less standardized for the current cohort of older adults compared to earlier cohorts, research on intimate relationships of older adults in the U.S. has yet to begin to explore in much detail and depth the varied ways of repartnering in later life. This symposium begins this exploration by examining three different topics of repartnering; the pursuit of new relationships, living apart together (LAT), and remarriage. The first paper draws on qualitative interviews with older adults who use internet dating sites to examine the topic of pursuing new romantic relationships in later life. The second paper uses constructivist grounded theory analysis of in-depth interviews with older adults in LAT relationships in order to explore how this form of repartnering can represent a site to resist as well as conform to heteronormative ideology. The third paper extends our knowledge of the relationship between first marriages and health, to discover whether similar mental health benefits are found for remarried older adults.

### THE PURSUIT OF LOVE IN LATE LIFE: NEW INSIGHTS INTO AN AGELESS ENDEAVOR

E.B. Levaro, K. Hooker, A.J. Walker, *Human Development and Family Sciences, Oregon State University, Corvallis, Oregon*

Although the desire for love, romance, and sexual intimacy does not end in the later decades of life, it may be challenging for older adults to find new partners, whether for companionship, LAT relationships, cohabitation, or marriage. Despite considerable interest, little is known about how women and men in their 70s, 80s, and beyond experience the pursuit of intimate relationships. We report findings from a qualitative study framed by feminist and critical social gerontology and interpretive phenomenology. Thirteen women and 13 men (M age = 76.5, range = 70 to 92) who were actively seeking romantic partners through classified ads or listings on Craigslist or Match.com participated in in-depth semistructured interviews. Utilizing the lenses of age relations and gender relations, we discuss the meaning of informants' experiences and perceptions of dating relationships, their attitudes about sexuality, and their views of themselves and each other as aging men and women.

### RE-DOING RELATIONSHIPS IN LATER LIFE: HETERONORMATIVITY AND LIVING APART TOGETHER

D. Brothers, *Miami University, Oxford, Ohio*

The dominant ideologies at work in the study of heterosexual relationships often include the assumptions of heteronormativity or the hegemonic ideals of heterosexuality, traditional gender norms and family values. Our understanding of these qualities within heterosexual relationships of older adults is mostly within the context of long-term marriages, showing how in the empty nest phase, wives become more agentic and husbands become more communal. Later-life repartnering in general, and living apart together (LAT) specifically, creates a unique context to explore the extent to which heteronormativity dominates relationships in a life stage no longer ruled by family formation or, in the case of living apart together, the desire to share a household. This paper uses constructivist grounded theory analysis of in-depth interviews with twenty older adults to explore the ways older men and women conform to and resist heteronormative ideals in their LAT relationships.

### REMARRIAGE IN LATER LIFE: IMPLICATIONS FOR MENTAL HEALTH

J. Bulanda, *Miami University, Oxford, OH*

Although numerous studies find that married adults are healthier than the unmarried, it is less clear if marriage benefits apply equally to first- and higher-order marriages. Research is particularly lacking on mental health consequences of remarriage for older adults, having largely concentrated on union dissolution through widowhood, and mostly neglected union formation that occurs in the later years. This study uses data from six waves (1998-2008) of the Health and Retirement Study (HRS) to examine mental health before and after remarriage. The analysis begins with a sample of previously-married, single older adults in 1998. Baseline mental health is measured by an eight-item scale from the CES-D. Respondents' previous marital status, including type and number of unions, is controlled. Baseline CES-D score, previous marital status and characteristics, and demographic, socioeconomic, and health factors are all included as independent variables in models examining change in depressive symptoms over the transition to remarriage.

## SESSION 175 (SYMPOSIUM)

### SOCIAL RELATIONSHIP DYNAMICS IN AGING RELATED LIFE CONDITIONS

Chair: *J. Wagner, University of Erlangen-Nuremberg, Erlangen, Germany*
Co-Chair: *F.R. Lang, University of Erlangen-Nuremberg, Erlangen, Germany*
Discussant: *R. Blieszner, Virginia Polytechnic Institute and State University, Blacksburg, Virginia*

More recently, empirical findings have shed new light on the age-specific constraints and potentials of social relationships across adulthood and late life. Dynamics of interpersonal contexts and the personal capability to adapt to aging-related challenges play a pivotal role in maintaining well-being and functionality in everyday life. The major objective of this symposium is to bring together a collection of empirical papers that examine social relationship dynamics across different aging related life conditions and their potentials for the quality of social relationships. H.H. Fung & T. Li present empirical data on perceived partner discrepancies in marital relationships and their effects on marital quality in late adulthood, J. Lee and S.H. Zarit examine couple's differences in the support given and perceived quality of relationships with adult children, and how the dyadic patterns of these scores affect their marital relationship, J. Wagner and colleagues deal with lifelong dynamics and challenges within childless couples and look at possible consequences on life satisfaction, and M.K. Rohr et al. address dyadic negotiation in the transition to caregiving and possible effects on health and subjective well-being of both partners. The discussion by R. Blieszner will integrate the four empirical papers, highlight the importance of the consideration of psychosocial dynamics across the entire life span, and discuss possible future directions that research on social relationship dynamics should take.

### DIMENSIONS OF THE RELATIONSHIPS BETWEEN PARENTS AND THEIR ADULT CHILDREN: IMPLICATIONS FOR MARITAL SATISFACTION

J. Lee[1], S.H. Zarit[1], M. Rovine[1], K.L. Fingerman[2], K.S. Birditt[3], *1. Human Development and Family Studies, Penn State University, University Park, Pennsylvania, 2. Purdue University, West Lafayette, Indiana, 3. Institute of Social Research, University of Michigan, Ann Arbor, Michigan*

Parents and children maintain active relationships throughout their adult lives, and these interactions may affect the older couple's marriage. Using a sample of 197 couples from the Family Exchange Study, we conducted a dyadic analysis to examine how two dimensions of the relationships between parents and their adult children affect marital satisfaction: how much support is exchanged by each parent with children and differences in parents' feelings toward children. As expected, wives gave and received more support from adult children but contrary to equity theory, these differences in support between husbands and wives did not affect marital satisfaction. When wives felt more ambivalent toward children than husbands, marital satisfaction was lower. These results show the importance of gender roles, that is, wives' feelings toward children had more of an impact on the couple's marital satisfaction than did husbands' feelings.

### CHILDLESS COUPLES: PARTNERSHIP DYNAMICS IN MIDDLE AND LATE ADULTHOOD

J. Wagner[1], F.R. Lang[1], C. Wrzus[2], F.J. Neyer[3], *1. University of Erlangen-Nuremberg, Erlangen, Germany, 2. Max-Plank Institute of Human Development, Berlin, Germany, 3. University Jena, Jena, Germany*

For long-term couples, not having children often entails some challenges for the partners with regard to the dynamics and adjustment processes within the dyad. It is an open question, what consequences result from childlessness on the quality of long-term marriages in midlife and old age. Our research focuses on two related issues: First, we examine patterns of relationship regulation in voluntary and involuntary childless couples of middle adulthood, and second, we compare dyadic relationship patterns of childless couples in middle and late adulthood. Our sample consists of 196 participants (98 dyads) with 152 middle-aged and 44 old individuals. The assessment included relationship specific ratings such as partnership distress and individual characteristics. Preliminary results indicate age-differential associations between relational stress and life satisfaction. Particularly older women are affected by relationship specific perceptions of their husband. Findings are discussed in the light of age-specific challenges and possible adaptive mechanisms of partnership stabilization.

### RELATIONSHIP REGULATION IN THE TRANSITION OF CARE

M.K. Rohr, S. Engel, F.R. Lang, *Institut of Psychogerontology University Erlangen-Nuremberg, Erlangen, Germany*

Numerous studies have explored the role and impact of relationship quality in the context of caregiving. Due to theoretical and methodological challenges the role of relationship regulation in the transition to care remains an open question. Drawing on an action-theoretical perspective and applying a multi-methodological approach, the current project investigates the role of individual (e.g. personality, cognition, health) and contextual aspects (social embeddedness, urgency of care needs) within the transition to care. The present study focuses on dyadic negotiation between older adults and their potential family caregivers (N = 70 dyads). We illustrate the balancing of positive and negative relationship aspects when one is confronted with age-related health problems of a family member. Preliminary results point to the critical impact of regulative management on health and subjective well-being of both partners in the caregiving relationship.

### PARTNER DISCREPANCIES AND MARITAL QUALITY ACROSS ADULTHOOD: IS YOUR IDEAL OR EXPECTED STANDARDS ABOUT YOUR PARTNER MORE IMPORTANT?

H. Fung, T. Li, *Chinese University of Hong Kong, Hong Kong, China*

Previous studies have established a negative association between perceived partner discrepancies and marital quality, but the partner discrepancies in these studies are ill defined. The present study examined the relationship between partner discrepancies and marital quality in 56 couples aged from 20 to 79 years old. Two levels of partner standards (i.e., ideal and expected standards) and two domains in couple interaction (i.e., personality and support) were considered. We found that husbands' marital quality was significantly related to own ideal-actual partner personality discrepancy and expected-actual partner support discrepancy, whereas wives' marital quality was not only significantly related to own ideal-actual partner personality and support discrepancies, but also related to the husbands' ideal-actual partner personality discrepancy. Husbands' ideal-actual partner personality discrepancy and expected-actual partner support discrepancy were also found to mediate the curvilinear age differences in their martial quality. The results suggest that the level of partner standards, the specific domain in couple interaction, and the developmental stage in life span all need to be considered in future studies about partner discrepancies.

## SESSION 180 (SYMPOSIUM)

### THE COMPLEX INTERPLAY OF SLEEP AND COGNITION IN OLDER ADULTS

Chair: *A.P. Spira, Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland*

Sleep complaints are highly prevalent among older adults, and researchers are linking poor sleep to a growing number of adverse health outcomes. Cognitive impairment also is common in older individuals, and is associated with great disability and economic cost. Despite the prevalence of both sleep disturbance and cognitive impairment in elders, however, we have a limited understanding of their relationship. To increase our knowledge in this domain, studies of sleep and cognition are needed that use objective sleep assessment methods (e.g., actigraphy, polysomnography) and rigorous measures of cognition (e.g., neuropsychological test batteries, adjudicated diagnosis of cognitive disorders). In the proposed symposium, we will present new findings from studies in two large cohorts of older women and men: the Study of Osteoporotic Fractures and the Osteoporotic Fractures in Men Study, respectively. Specifically, we will present studies of: the link between objectively measured sleep duration/fragmentation and performance across cognitive domains; the association between sleep-disordered breathing and subsequent diagnoses of mild cognitive impairment and dementia; whether reaction time mediates the association between sleep disturbance and falls; and the association between objectively measured sleep and cognitive decline. We will discuss potential public health implications of our findings, including the possible impact of treating sleep disturbance on prevention of cognitive decline and other disability.

### ACTIGRAPHIC SLEEP AND NEUROPSYCHOLOGICAL TEST PERFORMANCE IN VERY OLD WOMEN

A.P. Spira[1], K.L. Stone[2], S. Redline[3], K. Ensrud[4,5], K. Yaffe[6,7], *1. Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 2. California Pacific Medical Center Research Institute, San Francisco, California, 3. Case Western Reserve University, Cleveland, Ohio, 4. University of Minnesota, Minneapolis, Minneapolis, Minnesota, 5. Minnepolis VA Medical Center, Minneapolis, Minnesota, 6. University of California, San Francisco, San Francisco, California, 7. San Francisco VA Medical Center, San Francisco, California*

Sleep disturbance has been linked to cognition in elders, but little is known about the association between objectively measured sleep and neuropsychological test performance in the very old. We studied 830 mostly white women aged 87.5 ±3.0 years who completed wrist actigraphy and seven neuropsychological tests. In adjusted analyses, longer sleep time (per standard deviation (SD)) was associated with impairment (>1.5 SD below mean) on the 3MS (OR = 1.44, 95% CI 1.08, 1.93) and a verbal (letter) fluency test (OR = 1.65, 95% CI 1.21, 2.25); there was a trend toward an association with executive dysfunction (Trails B; OR = 1.40, 95% CI 0.97, 2.02). Greater wake after sleep onset (per SD) was associated with impaired category fluency (OR = 1.41, 95% CI 1.10, 1.82). There was no association between sleep efficiency and test performance. In this presentation, we will provide further results and discuss implications for elders' functioning.

### SLEEP DISORDERED BREATHING, HYPOXIA, AND RISK OF MILD COGNITIVE IMPAIRMENT & DEMENTIA IN OLDER WOMEN

K. Yaffe[1,2], A. Laffan[3], S. Litwack Harrison[3], A.P. Spira[4], K. Ensrud[5,6], S. Ancoli-Israel[7], S. Redline[8], K.L. Stone[3], *1. University of California, San Francisco, San Francisco, California, 2. San Francisco VA Medical Center, San Francisco, California, 3. California Pacific Medical Center Research Institute, San Francisco, California, 4. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 5. University of Minnesota, Minneapolis, Minneapolis, Minnesota, 6. Minneapolis VA Medical Center, Minneapolis, Minnesota, 7. University of California, San Diego, San Diego, California, 8. Case Western Reserve University, Cleveland, Ohio*

Sleep-disordered breathing (SDB) is common among elders, but its association with cognitive impairment is unclear. We prospectively examined the association between SDB and subsequent diagnoses of mild cognitive impairment (MCI) and dementia in 298 women without dementia (mean age 82.3 ± 3.2) who completed polysomnography at baseline and had their cognitive status clinically adjudicated 5 years later. Women with SDB had a greater likelihood of MCI/dementia than women without SDB (44.8% vs 31.1%, odds ratio [OR] = 2.33, 95% confidence interval [CI] 1.28 - 4.25). Elevated oxygen desaturation index (≥15 events/hr of sleep) and percent sleep time with desaturation ≥3% increased odds of developing MCI/dementia (OR 2.05, 95% CI 1.15 – 3.67 and OR 2.23, 95% CI 1.10 – 4.54, respectively); percent sleep time with <90% oxygen desaturation and mean number of arousals/hour did not. Findings suggest that SDB greatly increases risk of cognitive impairment, and that hypoxia explains this association.

### ACTIGRAPHIC CHARACTERISTICS OF SLEEP, REACTION TIME, AND RISK OF FALLS IN OLDER WOMEN

K.L. Stone[1], T. Blackwell[1], A.P. Spira[2], K. Ensrud[3], J.A. Cauley[4], S. Ancoli-Israel[5], K. Yaffe[6], *1. Research Institute, California Pacific Medical Center, San Francisco, California, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 3. University of Minnesota, Minneapolis, Minnesota, 4. University of Pittsburgh, Pittsburgh, Pennsylvania, 5. University of California, San Diego, San Diego, California, 6. University of California, San Francisco, San Francisco, California*

Falls pose a major health risk among the older adults and are a leading cause of mortality, morbidity and premature nursing home placement. Sleep disorders are also extremely common, yet frequently underdiagnosed and untreated, particularly in the elderly. We recently published data from the Study of Osteoporotic Fractures, showing strong associations between actigraphic characteristics of sleep and fall risk in older women. In particular, the multivariate-adjusted odds of suffering two or more falls in the subsequent year was elevated for women who slept <=5 hours (OR=1.52; 1.03 – 2.24) compared to those who slept > 7 to 8 hours per night. Indices of sleep fragmentation were also associated with increased risk of falls. Using recently released data, we will present new data on the association between sleep characteristics and reaction time, and determine whether reaction time is a mediator of the association between sleep characteristics and fall risk among older women.

### SLEEP DURATION AND DISRUPTION: ASSOCIATIONS WITH COGNITIVE DECLINE IN OLDER MEN

A. Laffan[1], K.L. Stone[1], T. Blackwell[1], S. Ancoli-Israel[3], K. Ensrud[7,5], S. Redline[6], Y. Slinin[7,5], K. Yaffe[2,4], *1. California Pacific Medical Center, San Francisco, California, 2. University of California, San Francisco, San Francisco, California, 3. University of California, San Diego, San Diego, California, 4. San Francisco Veterans Affairs Medical Center, San Francisco, California, 5. Veterans Affairs Medical Center, Minneapolis, Minnesota, 6. Case Western Reserve University, Cleveland, Ohio, 7. University of Minnesota, MInneapolis, Minnesota*

Sleep complaints and cognitive impairment are common among older populations; however, the literature linking poor sleep and cognition relies on patient populations and self-reported sleep. We prospectively studied the effects of sleep quality (actigraphy defined total sleep time [TST], sleep efficiency [SE], and wake after sleep onset [WASO]) on cognitive decline (≥5 point decline 3MS or > 58 sec [mean + 1SD] increase Trails B time) over 4-years in the MrOS study, a community-based cohort of older men. In 2,370 men, 16.7% (395) met definition for decline on the 3MS and 10.8% (255) on the Trails B. Predictors of Trails B declines were lower SE (per SD, OR [95% CI]:1.14 [1.01, 1.28] and longer WASO (per 30 min, 1.10 [1.01, 1.20]) but not longer TST (per 30 min, 0.99 [0.94, 1.05]) (results were similar for 3MS). Measures of sleep disruption, but not duration, were associated with decline in cognitive function.

## SESSION 185 (POSTER)

## THERAPEUTIC INTERVENTIONS

### ART THERAPY TREATMENT IN ALZHEIMER'S DISEASE AND STROKE REHABILITATION

K.J. Edens, *Psychology, Sacramento State University, Sacramento, California*

Art therapy is an important method for addressing the psychological, emotional, and communication needs of patients with depression, dementia, Alzheimer's, and stroke. I conducted an art class for Alzheimer's and stroke rehabilitation patients in an assisted and independent living facility as part of the residents' daily activity selection to encourage socialization and creativity. The art class offered a variety of different mediums; water color, acrylic paint, pastel, and colored pencil, on canvas or paper. The class was conducted once a week for one to two hours with five to ten individuals. Students' capacity of functioning ability was measured by working unassisted for their first session. Over a six month period, I observed and monitored the correlates of art therapy with improvements in; emotions, cognition, visual perception, motor activity and function, as well as socialization. By comparing before and after drawings, the artwork demonstrated overall improvements in composition, color, and tone. Results also showed some confirmation of increased emotional well being, enhanced engagement in rehabilitation therapies, and improved psycho-social adjustment. This observation demonstrates a positive, holistic therapeutic approach, which could improve upon existing cognitive therapies that rely primarily on a verbal approach. The psychological aspects of brain-damaged patients often show anxiety, depression, and low self-esteem as a result of living with reduced capabilities caused by their condition. In conclusion, the objective of this method of therapy is to return the individual to independent functioning; this may be achieved through art therapy as a treatment modality in geriatric rehabilitation.

### EFFECT OF COMMUNITY SUPPORTIVE CARE PROGRAM FOR MAINTAINING DAILY LIVES OF ELDERS WITH DEMENTIA

S. Maruo[1], A. Kono[2], *1. The Doctoral Course, Graduate School of Nursing, Osaka City University, Osaka, Japan, 2. School of Nursing, Osaka City University, Osaka, Japan*

The purpose of the present study is to examine effects of community supportive care program for maintaining daily lives of elders with dementia to community-dwelling people. We provided group educational programs in three sessions dowering two or three months. Subjects who participated in all these sessions of the program were 106 persons living at home. Data were collected written questionnaires pre and post the programs, including image and knowledge of dementia, self-efficacy how support to elders with Behavioral and Psychological Symptoms of Dementia (BPSD). Of subjects, mean age was 69.9 years (SD, 6.9), and mean years of education was 12.3 years (SD, 2.0). A total of 78.3% (83 persons) of subjects were women, and 66.0% (70 persons) of them were maintained cognitive function. Regarding image of dementia, scores between pre and post programs were significantly improved, including 'ashamed' ($p <.0001$), 'sad' ($p =. 0006$), 'dementia is not disease' ($p =. 0023$) and 'not matter to me' ($p =. 0493$). A total scores of dementia knowledge ($p =. 0319$) and scores of self-efficacy which could support elders with BPSD in 'verbal or physical aggression' ($p =. 0356$) were improved at post problems. These results suggest that the programs could effect of image and knowledge of dementia, and self-efficacy how support to elders with BPSD to people living community.

### A COMMUNITY AND ACADEMIC PARTNERSHIP APPROACH TO IMPROVE HEALTH OUTCOMES IN A SENIOR HOUSING COMMUNITY

T.B. Hughes[1,2], C. Boyd[1], E.R. Giovannetti[1], D. Danner[2], *1. Division of Geriatric Medicine and Gerontology, Johns Hopkins University, Baltimore, Maryland, 2. University of Kentucky, Lexington, Kentucky*

In an effort to meet the objectives set forth by Healthy People 2010, public health officials, researchers and legislatures have begun to recognize the need for creative new approaches and interventions to address health disparities. To this end, a collaborative effort between researchers and residents of a low-income independent living facility in Lexington, KY sought to quantitatively evaluate the overall health status of residents and to qualitatively identify resident barriers to health care. Methods: A health needs assessment was performed with 75 residents and 5 focus groups were held with 35 residents of a low-income independent living facility. Results: Participants (n=75) were predominantly African American (80%) and low-income (94.7%: income <15,000) with ages 52-100 (mean=67.6). The majority of participants were obese (80%; BMI > 30) with multiple co-morbid conditions (96% had 2 or more chronic conditions). Focus group transcripts were analyzed using content analysis. Findings revealed the emergence of four central themes: a holistic perspective of health, the maintenance of independence as an integral aspect of health, the need for age-specific activities among young-old, old-old and oldest-old residents, and the need for support beyond chronic disease management for residents dealing with drug and alcohol issues. Conclusions: Findings revealed barriers to healthcare that may be uniquely germane to those living in low-income congregant housing settings and the need for innovative outreach and educational programs for these older residents.

### THE CHRONIC DISEASE SELF-MANAGEMENT PROGRAM IN RURAL COMMUNITIES: PARTICIPANTS' PERCEIVED BENEFITS

I.S. Harvey[1], L.L. Payne[2], M. Janke[4], C. Etkin[5], J. Wallace[2], H. Coyle[3], K. Broughton[2], *1. Kinesology and Community Health, University of Illinois Urbana Champaign, Champaign, Illinois, 2. Department of Recreation, Sport and Tourism, University of Illinois, Champaign, Illinois, 3. University of Illinois Extension, Champaign, Illinois, 4. University of South Florida, Tampa, Florida, 5. Rush University Medical Center, Chicago, Illinois*

Since nearly half of all persons in the United States have at least one chronic condition, meeting the complex needs of these individuals has become a challenge for our current health care system. Rural areas have a higher proportion of older adults and this population is likely significantly affected by chronic disease. Based on these factors, it is evident that providing programs to help rural residents self-manage their chronic conditions is necessary, and that in rural settings, offering a general chronic disease management program may be more appropriate than trying to provide disease-specific (e.g., arthritis, diabetes) management programs. This study examined the experiences and perceived benefits of rural residents who participated in the (Stanford) Chronic Disease Self-Management Program (CDSMP). Qualitative data were obtained from six focus groups (N = 34 participants) using a semi-structured focused group guide. Thematic analysis was used to analyze the qualitative data and three prominent themes emerged from the examination of the focus group interviews with the rural CDSMP participants: 1) the use of social support to create and facilitate behavioral change; 2) self-management strategies used for behavioral change; and 3) the increased use of self-regulatory activities to improve physical health outcomes. Our findings support that this tailored chronic disease self-management program has positive influences for health outcomes on rural populations and have has important implications for the design and delivery of interventions to enhance active self-management behaviors among rural populations.

### TACKLING AGEING CONTINENCE THROUGH THEORY, TOOLS AND TECHNOLOGY (TACT3)

M.L. Gilhooly[1,2], E. van den Heuvel[1,3,2], F. Jowitt[1,3,2], I. Sutherland[1,3,2], J. Bichard[4], P. Gaydecki[5], N. Ratcliff[6], S. Parker[7], *1. Brunel University, Uxbridge, England, United Kingdom, 2. Brunel Institute for Ageing Studies, Uxbridge, England, United Kingdom, 3. Brunel Institute for Bioengineering, Uxbridge, England, United Kingdom, 4. Royal College of Art, London, England, United Kingdom, 5. University of Manchester, Manchester, England, United Kingdom, 6. University of the West of England, Bristol, England, United Kingdom, 7. University of Sheffield, Sheffield, England, United Kingdom*

Incontinence is a precursor to social isolation, loss of self esteem and depression. The aim of this project is to reduce the impact of continence difficulties and, thus, assist older people in maintaining a positive identity and good quality of life. The TACT3 project is comprised of three research workpackages: Challenging Environmental barriers to continence: Two sets of stakeholders are involved, older people with continence difficulties and toilet providers. Focus groups, workshops, interviews and photographic diaries have been conducted to identify key issues. A design tool and pictorial reference cards will be produced. Improving continence interventions and services: 140 patients and their carers are being interviewed twice within a 12 month interval from a specialist continence clinic for older people and generic continence clinic. Twenty Health and social care managers and 200 practitioners will also be interviewed. Care outcomes will be analysed from each clinic and a cost benefit analysis will be carried out. Developing assistive devices: A colour change odour indicating formula has been developed to indicate the presence of the odour of urine at a just imperceptible level. A washable fabric underwear wetness sensor and alert mechanism is in the process of being developed. User opinion is currently being gathered via focus group to identify desired forms for the sensor and underwear. The preliminary findings from the first two years of this three year interdisciplinary project will be presented. The assistive devices will be on display. This research is funded by the UK New Dynamics of Ageing Programme.

### TTAP METHOD© RESEARCH: ENHANCING COGNITIVE AND PSYCHOSOCIAL WELL-BEING IN ALZHEIMERS DISEASE

L. Levine- Madori[1], E. Coveney[2], *1. Department of Social Sciences,Memory and Evaluation Services, St. Thomas Aquinas/Cornell University, Principle Investigator, Chappaqua, New York, 2. Beechtree Healthcare Center, Ithaca, New York*

The TTAP Method™ synthesizes the past decade of research in the fields of neuroscience, psychology, education, into a systematized and replicable multimodal creative arts approach. The TTAP Method™ developed in 2005, to enhance the global functioning of those diagnosed with Alzheimer's disease within a nine step format (Levine Madori, 2007). Simultaneously, through TTAP Method™ assessment forms and activity analysis protocols ensure replication through structured documentation, and evaluation of services thus furthering clinical research specifically in the area of Arts and Alzheimer's disease (Levine Madori, 2009a, 2009b, 2009c, Levine Madori & Alders, 2010). To date, the TTAP Method™ has been utilized successfully in 5 studies, and has National Certification Training for both professionals and caregivers. This non-pharmaceutical approach has proven to enhanced cognition as well as impacting quality of life issues in mild and moderate AD (Levine Madori, 2007, 2009a, 2009b, 2009c, Levine Madori, L.& Alders, A.,2010). The challenge facing health care professions, specifically therapists, is the lack of reliable, methods and modalities that are culturally sensitive (Alders, 2008, 2010) for recording, collecting, and evaluating clinical findings in formats that benefits long-term data collection (Fernandez et al., 2006).The TTAP Method™ was developed to meet these significant needs nationally and globally, being translated into Finnish in 2009. This paper focuses on studies completed, variables measured, the data collection, analysis and evaluation of findings. Discussion of two National studies utilizing the TTAP Method ™ where all interdisciplinary team members received the TTAP Method Certification Course Training prior to intervention will end this presentation.

## SESSION 190 (SYMPOSIUM)

### MILLION AND COUNTING: ELDERCARE ISSUES IN CHINA

Chair: *G. Guo, Peking University School of Nursing, Beijing, China*
Discussant: *L. Phillips, University of California School of Nursing, Los Angeles, California*

Elder people already accounted for 12.5% of the overall population in China, and over 20% in major cities. The ways of eldercare in China are affected by family structure changes and social-economic system reform. Emerging phenomena indicate the importance of mental health of frail elders and family caregivers within a society in transition. This symposium aimed identifying mental health issues among elders in Mainland China and Macau; and discussing caregiving related mental health issues in families of persons with dementia. Four papers will be presented in this symposium. The first paper, "Three-Wait-Citizen: Lived Experiences of Older Persons with Depression in Macau", uses qualitative and quantitative methods to explore the nature and meaning of depressive experiences among elders in Macau. Three meta-categories were drawn from the dominant categories reflected across the findings. The second paper, "Post-operative Depression and Rehabilitation Status in Elders with Hip Fracture", reports on the high incidence of post-operative depression among elders with hip fracture and its negative relationship with post-operative rehabilitation. The third paper,"Facing Challenges of Family Caregivers of Demented Elders: Roles of Caregiving Appraisal and Coping", tests Dementia Caregiving Model and investigates roles of caregiving appraisal and coping in relationship between caregiving stressors and caregiver psychological health. The forth paper, "Effect of One-year Nursing Intervention on Negative Emotions and Burden of Family Caregivers Caring for Homebound Elders with Dementia", provides evidence for community-based dementia care and demonstrates nursing intervention can help reducing anxiety and caregiving burden in families with dementia elders.

### THREE-WAIT-CITIZEN: NARRATIVES OF LIVED EXPERIENCES OF OLDER PERSONS WITH DEPRESSION IN MACAU

W. Zeng, *Kiang Wu Nursing College, Macau, Macao*

The study aims to interpret the lived experiences of 31 older persons with depression in Macau. The principal influences on depression were indentified and an explanatory framework constructed as a basis to indicate possible risk factors for depression and to inform the future development of interventions for depression among older persons in Macau. By adopting mixed methods, using both qualitative and quantitative approaches, it has been possible to gain, for the first time, a deeper understanding of the nature and meaning of experiences of older persons with depression in Macau. These lived experiences clustered into four broad dominant categories: negative thinking, physical limitations and complaints, present living conditions and social support, and the lives they have lived. Three meta-categories are drawn from the dominant categories reflected across the findings; physical/material meta-category, social/family meta-category, and mental suffering meta-category. The associated explanatory framework models the relationships between the three meta-categories.

### THE STUDY ON POST-OPERATIVE DEPRESSION AND REHABILITATION STATUS IN THE ELDERS WITH HIP FRACTURE

P. Yang, *Medical & Surgical Nursing Department, Peking University School of Nursing, Beijing, China*

Objective: To explore the relationship between post-operative depression and rehabilitation status among elders with hip fracture. Method: 73 post-operative elders with hip fracture were interviewed. Elders' depression was assessed by Geriatric Depression Scale (GDS), current physical rehabilitation status was assessed by Barthel Index and Harris Hip Joint Function Scale, and quality of life was assessed by Health Survey Questionnaire (SF-36). Result: Depression was a serious problem among elders after hip surgery, with an incidence rate of 38.36%. Depression had significant negative effects on hip functional rehabilitation($r=-0.478$, $P<0.001$), ADL($r=-0.504$, $P<0.001$), and quality of life($r=-0.305$~$-0.652$, $P=0.000$~$0.009$). Conclusion: High incidence of post-operative depression had negatively affected elders' post-operative rehabilitation. It is suggested that nurses should provide effective psychological support to alleviate the depressive emotion in elders with hip fracture, and to promote functional recovery and improve the quality of life.

### FACING CHALLENGES OF FAMILY CAREGIVING OF DEMENTED ELDERS: THE ROLE OF APPRAISAL AND COPING

Y. Liu, K. Insel, *The University of Arizona College of Nursing, Tucson, Arizona*

This study tested a model developed to understand caregiving of elderly with dementia in China based on theories of stress and coping and investigated the role of caregiving appraisal and coping on caregiver stressors and psychological health. Ninety-six family caregivers (mean age 59, range 25-83 years) completed measures of subjective burden, presence of behavioral problems, satisfaction, coping strategies, and psychological health. Path analysis showed the original model did not fit the data ($\chi 2(9, N=96)=39.20$, $p=.000$; GFI= .91, NFI= .71; RMSEA=.19). Model modifications were conducted. The final model showed a perfect fit ($\chi 2(10, N=96)=8.14$, $p=.62$; GFI= .98, NFI= .94; RMSEA=.00). Caregiving subjective burden and coping mediated the relationship between stressors and caregiver psychological health. Caregiving satisfaction did not play a mediating role as expected, but had an indirect effect on psychological health through coping. Findings of the study will facilitate development and testing of interventions for caregivers in China.

### EFFECT OF ONE-YEAR NURSING INTERVENTION ON NEGATIVE EMOTIONS AND BURDEN OF FAMILY CAREGIVERS CARING FOR HOMEBOUND ELDERS WITH DEMENTIA

S. Shang, *School of Nursing, Peking University, Beijing, China*

Objectives: To evaluate effects of a one-year nursing intervention on negative emotions and caregiving burden suffered by spouse caregivers of homebound dementia patients. Methods: 53 caregivers were randomly assigned to control and intervention groups. Intervention group received regular home-visit, telephone follow-up and consultations on problem-based guidance of caregiving, stress-coping skills, and social support. Caregivers' depression, anxiety, and burden were measured by Self-rating Depression Scale, Self-rating Anxiety Scale and Caregiver Burden Inventory at 3-month intervals. Results/Findings: There was no significant difference in spouse caregivers' depression between the two groups ($P>0.05$). Spouse caregivers in intervention group were less anxious, felt less burden than those in control group at the 9th month of intervention and remained stabile at the 12th month($P>0.05$). Conclusions: This study provided evidence for community-based dementia care. Nursing intervention can help reducing anxiety and burden in spouse caregivers of homebound patients with dementia.

## SESSION 195 (SYMPOSIUM)

### BODY COMPOSITION CHANGES AND MUSCLE FUNCTION: TARGETS FOR PRESERVING HEALTH AND FUNCTION

Chair: *E.S. Strotmeyer, Epidemiology, University of Pittsburgh, Graduate School of Public Health, Pittsburgh, Pennsylvania*
Discussant: *A.B. Newman, Epidemiology, University of Pittsburgh, Graduate School of Public Health, Pittsburgh, Pennsylvania*

Loss of muscle mass and muscle function - power and strength - are common with aging. The decline in muscle function is proportionally greater than the loss of mass, though both are associated with poor physical function and disability. The symposium will describe trajectories of body composition changes from several longitudinal epidemiologic studies in aging populations and relate these to mortality (Dr. Watson) and insulin resistance (Dr. Lee). The Health, Aging and Body Composition (Health ABC) Study enrolled 3075 Medicare-eligible, well-functioning ambulatory adults aged 70-79 years old (52% women, 42% black) in Pittsburgh, PA & Memphis, TN in 1997-98, with contacts every 6 months and annual exams through 2000-01 and bi-annually thereafter. The Study of Osteoporotic Fractures in Men (MrOS) enrolled 5,995 community-dwelling, ambulatory men aged aged 64-92 years in 2000-02 from 6 U.S. centers with a follow-up exam 4.6 ± 0.3 years later. We will additionally describe the importance of preserving muscle function for maintenance of physical function. The relationship of muscle function to high physical function in the oldest old from Health ABC (Ms. Ward) and recovery from a simulated trip (Dr. Marsh) will be presented. The discussion will focus on future directions for addressing body composition changes and loss of muscle function in order to prevent physical function decline and disability in older adults.

### LONGITUDINAL LOSS OF LEAN MASS AND MORTALITY RISK IN OLDER ADULTS

N.L. Watson[1], T.B. Harris[2], S.B. Kritchevsky[3], S. Satterfield[4], T.F. Hue[5], A.B. Newman[1,6], *1. Department of Epidemiology, University of Pittsburgh, Pittsburgh, Pennsylvania, 2. Intramural Research Program, National Institute on Aging, Bethesda, Maryland, 3. Wake Forest University School of Medicine, Winston-Salem, North Carolina, 4. University of Tennessee Health Science Center, Memphis, Tennessee, 5. University of California San Francisco, San Francisco, California, 6. Department of Medicine, University of Pittsburgh, Pittsburgh, Pennsylvania*

Involuntary loss of lean mass in aging may predict mortality independent of weight loss. Total lean mass (kg) was evaluated by DEXA at baseline and after four years in 2,264 black and white participants in the Health, Aging and Body Composition study. Subsequent mortality was ascertained among 1,533 (68%) participants with no evidence of weight loss ≥ 3% (mean age at followup ± SD 77.4 ± 2.8 yrs; 48% male; 36% black). 279 deaths occurred by the end of follow-up (median 5.4 years). In a multivariable Cox proportional hazards model predicting mortality, lean loss over four years was associated with higher risk after adjustment for demographics: HR (95% CI) 1.49 (1.13-1.98) for lean loss ≥ 3% (N=284; 19%), relative to participants with lean loss or gain within 3% (N=980; 64%). Lean mass loss over four years predicted mortality among older adults with no evidence of weight loss.

### INCREASED RISK OF LEAN MASS LOSS ASSOCIATED WITH INSULIN RESISTANCE IN OLDER MEN

C.G. Lee[1], E.J. Boyko[2], E.S. Strotmeyer[3], P.M. Cawthon[4], A.R. Hoffman[5], S. Everson-Rose[6], E. Barrett-Connor[7], E. Orwoll[1], *1. Oregon Health & Science University, Portland, Oregon, 2. VA Puget Sound Health Care System, Seattle, Washington, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, 4. California Pacific Medical Center Research Institute, San Francisco, California, 5. Stanford School of Medicine, Palo Alto, California, 6. University of Minnesota, Minneapolis, Minnesota, 7. University of California, San Diego, California*

Body composition changes associated with insulin resistance (IR) were examined in 3497 non-diabetic men aged 64-92. Baseline IR was calculated using HOMA-IR. Baseline total fat, total lean, truncal fat and appendicular lean masses were measured using DXA and 4.6±0.3 years later. Greater % loss of weight, total and appendicular lean masses and lower % gain in total and truncal fat occurred with increasing HOMA-IR quartiles (p<0.001 for trends). In adjusted models, insulin-resistant men (Q4) vs. Q1 had higher odds of ≥ 5% loss in weight [OR 1.52 (95% CI 1.16, 1.99)] and lean mass [total: OR 1.90 (95% CI 1.43, 2.52); appendicular: OR 1.58 (95% CI 1.25, 2.00)] and lower odds of ≥ 5% gain in fat mass [total: OR 0.62 (95% CI 0.50, 0.77); truncal: OR 0.61 (95% CI 0.49, 0.76)]. Greater lean mass loss and lower fat gain occurred in non-diabetic, insulin-resistant men. IR may accelerate age-related sarcopenia.

### LEG POWER AND FUNCTIONAL MOBILITY IN THE OLDEST OLD: THE HEALTH, AGING AND BODY COMPOSITION STUDY

R.E. Ward[1], R. Boudreau[1], C. Rosano[1], M.A. Newman[1], B. Goodpaster[1], T. Harris[2], A.B. Newman[1], E.S. Strotmeyer[1], *1. Epidemiology, University of Pittsburgh, Pittsburgh, Pennsylvania, 2. National Institute on Aging, Bethesda, Maryland*

Power differs from strength since it measures muscle force and velocity and is dependent on nervous and musculoskeletal systems, though is not well-characterized in high-functioning older adults. We examined cross-sectional relationships between power from a pneumatic resistance machine and physical function in 37 participants (age=83.4±2.7, BMI=27.3±4.4, female=51.4%, black=37.8%) from the Health, Aging and Body Composition Study Pittsburgh site. Adjusting for age, sex, race and BMI, one standard deviation greater power was associated with higher likelihood of reporting "very easy" to walk 1/4 mile (OR=3.00; CI:1.05-8.59), climb 10 stairs (OR=3.79; CI:1.20-11.96) and rise from a chair (OR=3.98; CI:1.21-13.05) and 0.29 m/s faster walking speed (p<0.01). Additional adjustment for diabetes attenuated associations between power and physical function, explaining a portion of this association. Power may be important for maintaining high physical function in the oldest adults. We are currently collecting longitudinal power data in this cohort to examine trajectories of change.

### RECOVERY FROM A SIMULATED TRIP IN OLDER NORMAL AND OBESE OLDER ADULTS

A. Marsh[1], E.C. Haakonssen[1], J.A. Zaccaria[1], D. Pamukoff[1], M. Madigan[2], *1. Health and Exercise Science, Wake Forest University, Winston Salem, North Carolina, 2. Virginia Polytechnic Institute and State University, Blacksburg, Virginia*

Muscle power may be more important than muscle strength for regaining balance following a slip or trip but there are scant data to support this contention. Whether or not obesity plays a role in compromising the ability to recover is also unknown. Thus far we examined the ability to recover from a forward leaning posture in 4 normal BMI (NORM, mean=24.6±2.1 kg/m^2) and 6 obese BMI (OB, mean=33.4±2.8 kg/m^2) older adults (mean age=70.4±5.4 y). The outcome for this study was the maximal body lean angle from which an individual regained their balance. There was no significant difference in lean angle between NORM and OB (16.6±3.4 vs. 15.8±2.6 deg). The Spearman correlation between BMI and lean angle was r=-0.38 (p=.275). Both muscle strength and power were correlated to lean angle. Data will be collected on 16 subjects (8 NORM, 8 OB) who will be randomly assigned to power or strength training.

## SESSION 200 (POSTER)

## DISEASE AND GERIATRIC SYNDROMES

### LAB-BASED PHYSICAL TASKS TO INDUCE FATIGUE IN OLDER ADULTS WITH SYMPTOMATIC KNEE OR HIP OSTEOARTHRITIS

S. Schepens[1], A.K. Lyden[1], D. Wolford[1], A. Markel[1], S.L. Murphy[1,2], *1. University of Michigan, Ann Arbor, Michigan, 2. VA Ann Arbor Healthcare System GRECC, Ann Arbor, Michigan*

Introduction: Although osteoarthritis (OA) interventions focus predominantly on pain reduction, fatigue is emerging as a clinically important symptom. However, little is known about the fatigue experience in older adults with OA, making it difficult to address clinically. This study utilized lab-based, daily life tasks to induce fatigue and examined effects on fatigue and pain. Methods: Nine older adults with symptomatic knee or hip OA completed sweeping, grocery, and walking tasks in 15-minute circuits of increasing intensity. Participants were asked to stop when they felt too fatigued to continue. Fatigue and pain severity were self-reported (0 – 10 scale) following each circuit. At another visit, they completed physical performance tests. Results: Participants spent an average of 52.8±7.7 minutes performing tasks. On average, fatigue and pain increased by 3.4±0.9 (range 0 to 8) and 2.0±0.5 (range 1 to 5) units, respectively. Rates of change of fatigue and pain (symptom increase/time) were not significantly correlated (r=0.5, p=0.22). A physical performance test (timed up and go) was positively associated with rate of change in pain (r =0.8; p=0.02) but not with fatigue (r=0.4; p=0.28). Conclusions: Lab-based, daily life tasks induced both fatigue and pain in older adults with OA. The different rates of change and symptom severity, as well as the relationship of physical performance with pain and not fatigue supports the idea that fatigue and pain experiences are related but not the same. Our future study will examine carryover effects of lab-based tasks on symptoms and physical activity.

### FACTORS ASSOCIATED WITH FATIGUE AMONG OLDER ADULTS WITH SYMPTOMATIC KNEE OR HIP OSTEOARTHRITIS

S.L. Murphy[1,2], N. Alexander[2,1], D.M. Smith[3], A.K. Lyden[1], J.F. Koliba[2], B. Grincewicz[2], *1. Physical Medicine and Rehabilitation, University of Michigan, Ann Arbor, Michigan, 2. VA Ann Arbor Healthcare system GRECC, Ann Arbor, Michigan, 3. Stony Brook University, Stony Brook, New York*

Fatigue, one of the most frequently reported symptoms of osteoarthritis (OA), has been described by people with OA as debilitating, causing activity restriction, and greatly impacting life. Despite its clinical importance, few studies have examined fatigue in OA and there is no gold standard fatigue measure used in this population. Among adults aged 65 and older with painful knee or hip OA and reported fatigue (i.e., "moderate amount" or "most of the time" within the past week), we examined fatigue using the Brief Fatigue Inventory (BFI) and its association with several variables. Eighty-nine participants (61% female, 72.3 + 6.2 years) underwent performance testing and completed questionnaires during a lab visit. Participants had an average BFI score of 4.63 + 2.0 and an average WOMAC pain score of 8.9 + 3.3. A linear regression model was used to examine the relationship between fatigue and demographics, physical performance, sleep, pain, and depressive symptoms. Fifty percent of the variance in fatigue was explained by the model. Fatigue was most strongly related to pain (beta = .28; p = .0001) and depressive symptoms (beta = .10; p = .0001), whereas other variables (e.g., sleep efficiency and physical performance) were not significant. Thus in older adults with symptomatic OA, pain and depression, and, surprisingly, not sleep or physical performance, were independently associated with fatigue. Future interventions to alleviate fatigue in OA should consider not only pain, but also mood disorders.

### THE SYMPTOM EXPERIENCE IN OLDER MEN WITH PROSTATE CANCER RECEIVING RADIATION THERAPY

S.L. Beck[1], M. Caserta[1], J. Guo[1], B. Wong[1], L. Ellington[1], N. Honea[2], J. Smith[1], G. Towsley[1], *1. College of Nursing, University of Utah, Salt Lake City, Utah, 2. Arizona Oncology Services Foundation, Phoenix, Arizona*

Prostate cancer primarily occurs in older men and will afflict one in six men in their lifetime. Radiation therapy for localized prostate cancer has historically been associated with significant side effects including urinary and bowel problems as well as fatigue, insomnia, and depression. Recent advances such as Intensity-Modulated Radiation Therapy and the use of ultrasound to better target treatment of the prostate should result in an improved symptom experience. This report characterizes the symptom experience of men with prostate cancer who were over age 50 and receiving external radiation therapy +/- brachytherapy. Men were screened after receiving 40cGy using a systematic assessment of symptom occurrence and distress. The sample included 189 men ranging in age from 51 to 88 (median age of 69). The sample was primarily non-Hispanic white (90%). Eleven men (6%) reported no symptoms and 77 (41%) reported symptoms that were only mild in distress. The number of symptoms ranged from 0 to 12, median was 4. The most prevalent symptoms were urinary frequency (74%), fatigue (65%) and urinary burning (40%). There were very low levels of red or peeling skin (5%). The mean symptom distress for those who experienced any symptom was 2.34 (1 = not at all to 5 = extremely distressed). The associations between age and number of symptoms and symptom distress were non-significant, p-value > 0.35. In spite of advances in therapy, the majority of men regardless of age continue to experience symptoms that are distressing and targeted interventions are recommended. (NCI R21 CA120896-01A1).

### PREDICTORS OF HOME HEALTH UTILIZATION BY OLDER ADULTS HOSPITALIZED WITH HEART FAILURE

D. Bearden[1], M. Feller[1], L. Jones[1], Y. Zhang[1], A. Ahmed[1,2], *1. Medicine, UAB, Birmingham, Alabama, 2. Veterans Affairs Medical Center, Birmingham, Alabama*

Background: Heart failure (HF) is the leading cause of hospitalization for Medicare beneficiaries. HF patients are also major utilizers of home health care (HHC) services and many hospitalized HF patients are discharged home with HHC. However, little is known about the predictors of post-discharge HHC utilization for older adults hospitalized with HF. Methods: Of the 8555 Medicare beneficiaries discharged with a primary diagnosis of HF in 1998-2001 from 106 US hospitals, 6571 (77%) were discharged home alive. Of these, 1414 (22%) were discharged with HHC. We used logistic regression models, adjusting for demographic, clinical and care characteristics, to estimate odds ratios (OR) and 95% confidence intervals (CI) for HHC utilization. Results: Patients (n=6571) had a mean (+/-SD) age of 75 (+/- 11) years, 55 % were women and 26% were African American. Predictors of post-discharge HHC utilization included age (OR, 1.05; 95%CI, 1.04-1.06; P<0.001), female gender (OR, 1.33; 95% CI, 1.17-1.51; P<0.001), prevalent HF (OR, 1.35; 95% CI, 1.16-1.57; P<0.001), pulmonary edema by chest x-ray on admission (OR, 1.29; 95% CI 1.13-1.48;P<0.001) and beta-blockers (OR, 0.82; 95% CI, 0.71-0.95; p=0.006). Other predictors included comorbidities, intensive care unit use, lack of cardiology care, and care at rural or small hospitals (all P<0.05). Conclusion: One in five HF patients discharged home received HHC services. Several demographic, clinical and care characteristics predicted HHC utilization, which may help identify HF patients at high risk for HHC utilization.

### ASSOCIATION OF VITAMIN D LEVELS AND THE INITIATION OF CORONARY ARTERY BYPASS GRAFTING

J. Kautz, S.S. Cha, P.Y. Takahashi, *Internal Medicine, Mayo Clinic, Rochester, Minnesota*

Introduction: There is growing evidence of an association between lower vitamin D levels and coronary artery disease (CAD). Questions remain on the association between vitamin D levels and coronary artery bypass grafting (CABG). Specific Aim: To determine the association between vitamin D levels and the development of severe CAD requiring CABG. Material and Methods: This was a retrospective cohort study of over 1790 patients over age 60 in a primary care practice from years 2000-2007. The primary outcome was initiation of CABG in the following twenty four months. Vitamin D levels were placed within quartiles. Age, gender and Charlson comorbidity index served as adjustment cofactors. The primary analysis used multivariable logistic regression as well as a timed-to event analysis. Results: 129 patients (7.21%) of the cohort underwent CABG in the two years following index. Unadjusted vitamin D levels were associated with a decreased risk of CABG with an increasing vitamin D level (OR 0.98 95% CI 0.96-0.99) p value 0.0013. This relationship continued after adjustment for age and gender. After full adjustment for age, gender and Charlson score, the relationship became non-significant with an odds ratio of 0.99 (95% CI 0.98-1.01). Discussion: Vitamin D levels may play an important part of cardiovascular health. The full model does not show a relationship between vitamin D and CABG; however, the absolute number of events was low at 129. Given differences in models, vitamin D levels may also serve as a surrogate for poor health. Further studies are needed.

### SAFETY AND TOLERABILITY OF NEBIVOLOL IN SENIORS AND NON-SENIORS WITH STAGE I-II HYPERTENSION

F.W. Germino[1], W. Rowe[2], *1. Department of Internal Medicine, Rush Medical College, Chicago, Illinois, 2. Forest Research Institute, Jersey City, New Jersey*

Background: Hypertension, polypharmacy, and the number of comorbidities have been shown to increase with age, which makes the choice of antihypertensive therapy particularly important for the elderly. This analysis summarizes the safety and tolerability data of nebivolol, a cardioselective, vasodilatory beta-blocker, in seniors and non-seniors. Methods: Safety and tolerability data from 3 randomized, 12-week, multi-center, placebo-controlled trials of nebivolol (1.25-30/40 mg/day) in Stage I-II hypertension were pooled and stratified between seniors (≥65 years of age) and non-seniors (<65 years of age). Results: The stratified patient population comprised 375 seniors (nebivolol, n=345; placebo, n=30; mean age: 70.3 years) and 1641 non-seniors (nebivolol, n=1466; placebo, n=175; mean age: 49.8 years). Discontinuation rates due to AEs in nebivolol-treated seniors and non-seniors were 4.1% and 2.3%, respectively (placebo: 0% vs 2.3%). AEs were reported by 43.2% and 30.0% nebivolol-treated seniors and non-seniors, respectively (placebo: 44.8% vs 40.0%). In both nebivolol-treated seniors and non-seniors, the most frequent AEs were headache (5.2% vs 7.5%, respectively; placebo: 13.3% vs 4.6%) and fatigue (4.9% vs 3.3%; placebo, 3.3% vs 1.1%). Dizziness was experienced by 1.4% and 3.3% nebivolol-treated seniors and non-seniors, respectively (placebo: 0% vs 2.3%); orthostatic hypotension was experienced by 0% and 0.3% nebivolol-treated seniors and non-seniors, respectively (placebo: 0% vs 0%). In both seniors and non-seniors, there were no significant differences in frequency of AEs or clinically significant laboratory parameters between nebivolol (all doses)- and placebo-treated patients. Conclusions: The overall safety and tolerability profile of nebivolol is similar between seniors and non-seniors with Stage I-II hypertension.

## EXPLORING PSYCHOSOCIAL PATHWAYS BETWEEN NEIGHBORHOOD CHARACTERISTICS AND STROKE IN OLDER ADULTS: THE CARDIOVASCULAR HEALTH STUDY

T. Yan[1], J. Escarce[2], L. Liang[2], W. Longstreth[3], S. Merkin[2], B. Ovbiagele[2], S. Vassar[1], A.F. Brown[2], *1. Neurology, University of California Los Angeles, Los Angeles, California, 2. UCLA School of Medicine, Los Angeles, California, 3. Neurology, University of Washington, Seattle, Seattle, Washington*

Background: Studies have not investigated whether psychosocial pathways mediate the effect of neighborhood exposures on stroke. Methods: We used data from the Cardiovascular Health Study, a longitudinal population-based cohort study of adults >= 65 years, to construct race-stratified Cox proportional hazard models for time to first ischemic stroke. The key explanatory variable in the baseline model was an index of neighborhood socioeconomic status (NSES), constructed at the census-tract level from six measures of population income, education, employment and wealth. Covariates were individual sociodemographic characteristics (age, gender, marital status, education, and income). In subsequent models, we added psychosocial (depression, social support, social networks, and stressful life events), behavioral (smoking, physical activity, and alcohol), and biologic factors (EKG abnormalities, subclinical cardiovascular disease, hypertension, diabetes, and hyperlipidemia) separately and simultaneously to assess mediation of the effect of NSES on stroke. Results: Of the 3834 participants with no prior stroke, 548 had an incident ischemic stroke over the 11.5-year follow-up. Among the psychosocial factors, only depression was independently associated with higher stroke hazard (Hazard Ratio [HR]=1.26; 95% CI:1.02-1.59). However, addition of psychosocial factors to the baseline model slightly reduced the HRs among residents in the lowest relative to highest NSES quartile from 1.32 (1.01-1.74) to 1.30 (0.98-1.71). Depression ceased to be statistically significant in the model with behavioral and biological factors adjusted. We found no association between NSES and stroke incidence among African Americans. Conclusions: Psychosocial factors played a minimal role in mediating the effect of NSES on stroke incidence among whites.

## MILD CHRONIC KIDNEY DISEASE (STAGE-3A) AND POOR OUTCOMES IN MEDICARE BENEFICIARIES HOSPITALIZED WITH ACUTE HEART FAILURE

T.K. Winters, M.A. Feller, M. Mujib, B. Bowling, R. Campbell, I.B. Aban, A. Ahmed, *University of Alabama at Birmingham, Birmingham, Alabama*

Background: In patients with chronic heart failure (HF), mild chronic kidney disease (CKD) or CKD Stage-3A had no independent association with outcomes. The objective of this study is to determine if CKD Stage-3A is associated with poor outcomes in older adults with acute HF. Methods: Charts of 8049 Medicare beneficiaries discharged alive in 1998-2001 from 106 US hospitals with a primary diagnosis of HF were abstracted. Of these, 4965 had estimated glomerular filtration rate (eGFR) ≥45 ml/min/1.73m2, of which 2041 (41%) had CKD Stage-3A or eGFR 45–59 ml/min/1.73m2. Propensity scores for CKD Stage-3A were used to assemble a cohort of 1826 pairs of patients with and without CKD Stage-3A respectively, who were balanced on 58 baseline characteristics. Cox-regression models were used to estimate association of CKD Stage-3A with outcomes during 5 years of follow-up. Results: Matched patients had a mean (±SD) age of 76 (±10) years; 58% were women; 21% were African American. Patients with and without CKD Stage-3A had a mean eGFR of 52 and 78 ml/min/1.73m2. All-cause mortality occurred in 67% and 61% of matched patients with and without CKD Stage-3A respectively (hazard ratio for CKD Stage-3A, 1.18; 95% CI, 1.07–1.30; P=0.001). HF-hospitalization occurred in 58% and 56% of matched patients with and without CKD Stage-3A respectively (hazard ratio for CKD Stage-3A, 1.14; 95% CI, 1.02–1.28; P=0.027). Conclusion: Unlike in chronic HF, in older adults hospitalized with acute HF, the presence of CKD Stage-3A (eGFR 45–59) was associated with increased mortality and HF hospitalization.

## QUALITATIVE ANALYSIS OF CLINICAL LIFE COURSE BY OLDER PERSONS WITH NEUROFIBROMATOSIS 1

T. Teasdale[1,2], S. Karakattu[1,4], H. Rabalais[1], G. Hallford[1], P. Birch[3], B. Carnes[1], J. Friedman[3], J. Mulvihill[1], *1. Dept of Geriatric Medicine, University of Oklahoma, Oklahoma City, Oklahoma, 2. Veterans Affairs, Oklahoma City, Oklahoma, 3. The University of British Columbia, Vancouver, British Columbia, Canada, 4. University of Tennessee, Memphis, Tennessee*

The clinical picture of Neurofibromatosis 1 (NF1) in youth is well described. Two thirds of all people with NF1 survive past age 45, yet the issues of NF1 (as with many genetic disorders) in old age are largely unknown. Case reports suggest the medical problems, but we lack specific information guiding clinicians in the care of these older patients. As part of a larger initiative to define the issues that individuals with genetic disorders have in old age, focus groups and interviews were conducted in the USA and Canada. Self perceptions of aging, personal disease status, coping strategies, and the clinical experience were collected from persons with NF1 aged 50+, caregivers, and non-affected siblings. Nearly all unwaveringly stated that health care providers are under-trained in NF1 screening, management, and referral. Providers do not attend to issues of importance to affected older patients, including ADL/IADL limitations, pain, fatigue, health care costs, linking NF1 to symptoms, QoL, stigma, and future concerns (full listing will be presented). Instead, providers attend to the acute reason for the visit or to those medical conditions with which the provider is familiar. Inattention to NF1-specific health care issues had a negative impact on the respondents' quality of life and livelihood. Most respondents reported low levels of health care utilization, primarily because providers knew little about NF1. New QoL indicators and suggested clinical approaches for appropriate care of older persons with NF1 will be distributed. This approach may be transferable to other genetic diseases.

### EUROPEAN ANCESTRY AND RESTING METABOLIC RATE IN OLDER PERSONS

T. Manini[1], K. Patel[3], D.C. Bauer[5], E. Ziv[5], D. Schoeller[2], D. Mackey[5], A.B. Newman[4], T.B. Harris[3], *1. Aging and Geriatric Research, University of Florida, Gainesville, Florida, 2. University of Wisconsin, Madison, Wisconsin, 3. National Institute on Aging, Bethesda, Maryland, 4. University of Pittsburgh, Pittsburgh, Pennsylvania, 5. University of San Francisco, San Francisco, California*

Context: Resting metabolic rate (RMR) contributes 60-80% of total energy expenditure and is consistently lower in populations of African descent compared with populations of European populations. Genetic determination of European ancestry (EA) through SNP analysis would provide an initial step for indentifying genetic associations that contribute to low RMR in African Americans. Objective: We sought to evaluate the association between RMR and EA in African Americans. Design and Participants: RMR was measured by indirect calorimetry in 141 African American men and women (aged 74.7 ± 3.0 years). Ancestry informative markers were used to estimate individual percent EA. Multivariate regression was used to assess the association between RMR and EA after adjustments for fat-free mass, fat mass, age, study site, physical activity level and sex. Setting: University-based population research clinics in Memphis, Tennessee and Pittsburgh, Pennsylvania Main Outcome Measure: Resting metabolic rate Results: Mean EA was 23.8 ± 16% (range: 0.1% to 70.7%) and no differences were noted between sex. Following multivariate adjustment, each percent increment in EA was associated with a 1.6 kcal/day (95% Confidence interval: 0.42, 2.7 kcal/day) increase in RMR ($p = 0.008$). This equates to a 160 kcal/day lower RMR in a population of completely African ancestry compared with one of completely European ancestry. Additional adjustment for trunk fat-free mass that partially accounts for high-metabolic rate organs did not affect this association. Conclusions: European ancestry in African Americans is strongly associated with RMR, suggesting that population differences in RMR may be due to genetic variants.

### PHOTOSELECTIVE VAPORIZATION OF THE PROSTATE: OUTCOMES AND ADVERSE EVENTS OF 220 CONSECUTIVE PATIENTS

C.H. Robson, E. Mueller, *Urology, University of Texas Health Science Center San Antonio, San Antonio, Texas*

Purpose: To evaluate the short term outcomes of 220 consecutive patients who underwent the 532 nm KTP photoselective vaporization of the prostate (PVP) procedure and to evaluate and categorize the complications of the procedure. Materials and Methods: A total of 220 patients with symptomatic benign prostatic obstruction were treated with KTP photoselective vaporization of the prostate. Evaluation measures included the AUA Symptom Score (AUASS)/Quality of Life Score (QOL), peak urinary flow rate (Qmax), post void residual (PVR) and adverse events. Results: Symptoms were evaluated at 3 months and adverse events at 1 and 3 months. 181 patients returned for their 1 month visit and 152 returned for their 3 month visit. The American Urological Association Symptom Score (AUASS) decreased from 21.8 to 6.7. The Quality of Life Score (QOL) decreased from 3.8 to 0.7. The peak urinary flow rate (Qmax) increased from 10.7 cc/sec to 22.7 cc/sec. The post void residual urine (PVR) decreased from 262 cc to 105 cc. Most common adverse events in the early postoperative period were mild hematuria in 45%, mild transient dysuria in 32%, and transient irritative voiding symptoms such as urinary urgency and frequency in 31%. Conclusion: These results confirm that photoselective vaporization of the prostate (PVP) is a safe and effective therapy for benign prostatic obstruction.

### PREVALENCE OF URINARY CATHETERS: A PILOT STUDY OF ATTITUDES, USE, AND KNOWLEDGE

T. Dolinar[1], D.M. Kresevic[1,2], C.J. Donskey[1], C. Burant[3,1], B. Heath[1], *1. VA, Cleveland, Ohio, 2. University Hospitals Case Medical Center, Cleveland, Ohio, 3. Case Western Reserve University Frances Payne Bolton School of Nursing, Cleveland, Ohio*

Urinary tract infections (UTI) remain the most common hospital-acquired infection. The most frequent (80%) cause of developing UTI during an inpatient stay is catheter placement (Am J Infect Control, 2006). Each year over 5 million inpatients have urinary catheters inserted (CDC, 2001). Unfortunately, guidelines for appropriate catheter placement for urinary retention are lacking (Holroyd-Leduc et al., 2006; American Health Care Association, 2009). As phase one in a three phase study, Cleveland VAMC investigators conducted a web-based survey to determine current practices and attitudes of healthcare providers regarding indwelling catheter placement for elevated post-void residual (PVR) urine in older adults. Of the 46 initial respondents only 12% routinely measure PVR on new admissions despite the fact that 82% had a portable transabdominal ultrasound readily available on their unit to assess PVR. Over half of the respondents indicated they would only place a catheter in a patient with a PVR of 300 mL or higher; notably 91% of providers believed that elevated PVR of 300 mL can predispose an elderly patient to UTI. Less experience was associated ($r=-.53$, $p<.001$) with increased likelihood to recommend catheter placement in a patient with a PVR of 300 mL following hip replacement. However, more experience was associated ($r=.41$, $p<.01$) with the belief that a post-op knee replacement patient with an indwelling catheter would develop UTI. Studies to determine appropriate use of catheters for elevated PVR and associated risk of developing UTI are needed in order to establish guidelines for providers.

### INCIDENCE AND RISK FACTORS OF HEALTHCARE-ASSOCIATED INFECTIONS IN KOREAN NURSING HOMES FOR OLDER ADULTS

S. Choi, M. Song, *College of Nursing, Seoul National University, Seoul, Republic of Korea*

Background: Healthcare-associated infections (HAIs) are a major healthcare problem in nursing homes. There have been few reports related to HAIs in Korean nursing homes. Objectives: To identify the incidence and risk factors of HAIs in Korean nursing homes. Methods: A retrospective cohort study was done of 389 medical and nursing records of residents residing for more than one day in two nursing homes for older adults in Korea for one year beginning in June 2007. HAIs were defined according to the standard definitions developed by the Consensus Conference. Results: A total of 484 cases of HAIs were identified in 258 (66.3%) residents during 118,002 resident-days. The overall incidence rate of HAIs was 4.1 per 1000 resident-days. Catheter-associated urinary tract infection incidence had the highest rate of 4.02 per 1000 catheter-days followed by respiratory infections (1.49 per 1000 residents-days), skin and soft tissue infections (1.2 per 1000 residents-days), gastrointestinal tract infections (0.85 per 1000 resident-days), and urinary tract infections (0.40 per 1000 residents-days). Using a multivariate regression model, risk factors of HAIs were present for invasive devices [Odds ratio (OR) 3.02], length of stay greater than 2 years (OR 2.73), bedridden status (OR 2.70), and gender for males (OR 2.05). Conclusions: This is the first study about HAIs in nursing homes in Korea. The results of this study enable meaningful comparisons with other countries as well as contribute to preventing infections in nursing homes by implementing infection control programs. However, the small study sample and retrospective method limit our observations.

### CIRCULATING LEVELS OF MACROPHAGE MIGRATION INHIBITORY FACTOR IN COMMUNITY-DWELLING OLDER ADULTS

S.S. Chang[1], M. Tinetti[1], R. Bucala[2], I. Kang[2], *1. Internal Medicine, Section of Geriatrics, Yale University School of Medicine, New Haven, Connecticut, 2. Yale University School of Medicine, Department of Internal Medicine, Section of Rheumatology, New Haven, Connecticut*

Background: A pro-inflammatory state, characterized by elevated circulating levels of tumor necrosis factor alpha (TNF-$\alpha$) and interleukin-6 (IL-6), has been associated with aging. Macrophage migration inhibitory factor (MIF) is a cytokine that activates the production of TNF-$\alpha$, IL-6, and other pro-inflammatory mediators in immunoregulatory cells (e.g., macrophages and lymphocytes). Also, MIF is reported to be associated with inflammatory diseases and age-related conditions, including atherosclerosis, diabetes mellitus, osteoporosis, and Alzheimer's disease. Whether higher circulating MIF levels are associated with aging, independent of disease-related effects, is unknown. To address this question, we compared plasma MIF levels between healthy older and younger adults. Methods: Morning blood specimens were collected from 27 adults aged ≥65 and 69 participants aged 21-40, recruited from the New Haven, CT area. Individuals with chronic inflammatory diseases or acute infections were excluded. Plasma MIF levels were measured by enzyme-linked immunosorbent assays. Using Wilcoxon-Mann-Whitney rank-sum tests, we assessed differences in median MIF levels between older and younger participants. Results: The median MIF level was 4.77 ng/ml (interquartile range(IQR):2.23-11.74) in older adults vs. 3.92 ng/ml (IQR:2.13-7.85) in younger adults (p-value=0.28). After excluding participants with hypertension and ≥2 diseases (n=16), the difference in median MIF levels between older (6.35 ng/ml, IQR:4.72-11.74) and younger (3.92 ng/ml, IQR:2.11-7.85) adults became significant (p-value=0.045). Conclusions: These results suggest that MIF levels may increase in healthy adults with aging, independent of age-related conditions and co-morbid disease burden. Whether MIF production differs in immunoregulatory cell subsets between older and younger adults needs to be investigated in future studies.

### BIOMARKERS OF SARCOPENIA FROM SKELETAL MUSCLE BIOPSIES IN MEN

T.W. Buford[1,3], M.B. Cooke[2,3], B.D. Shelmadine[3], G.M. Hudson[4,3], L.L. Redd[3], D.S. Willoughby[3], *1. University of Florida, Gainesville, FL, Florida, 2. University of Queensland, Brisbane, Queensland, Australia, 3. Baylor University, Waco, Texas, 4. University of Southern Mississippi, Hattiesburg, Mississippi*

Sarcopenia is a prevalent condition in older adults with significant costs to afflicted individuals and the healthcare system. Attaining viable biomarkers of sarcopenia is critical to improving treatment of the condition. The present study examined skeletal muscle biopsies from young (N=14, 21.35+1.03 yr) and aged (N=13, 63.85±1.83 yr) men for biochemical indices related to muscle atrophy through proteolysis and/or apoptosis. Pearson correlations coefficients and multiple regression analysis also indicated relationships of biochemical measures to muscle mass and strength. Our results indicated that gene expression of forkhead box O 1 (FoXO1, p=0.001) and inhibitors of DNA binding 1 (Id1, p=0.010) and 3 (Id3, p=0.043) was significantly greater in aged compared to young men. Moreover, aged muscle contained significantly more phosphorylated inhibitor of kappa B alpha protein (pIKB$\alpha$, p=0.016) as well as greater nuclear content of p53 (p=0.039), glucocorticoid receptor (GCr, p=0.006), and p65 subunit of nuclear factor kappa B (NF-kB, p=0.007). Pearson coefficients revealed significant correlations with both lean mass and strength for FoXO1 mRNA (lean mass r= -0.435, p=0.023; strength r= -0.402, p=0.038) and nuclear NF-kB p65 (lean mass r= -0.508, p=0.007; strength r= -0.383, p=0.048). Meanwhile Id1 (r= -0.474, p=0.012), Id3 (r= -0.583, p=0.001) and GCr (r= -0.489, p=0.010) correlated significantly with muscle strength. Regression models indicated p65 and FoXO1 as significant predictors of lean mass (adjusted R2=0.423), while Id1 was the only significant predictor of muscle strength (adjusted R2= 0.313). These results suggest several potential biomarkers that are worthy targets of new therapeutic interventions meant to treat sarcopenia.

### MEDICATION MANAGEMENT IN OLDER ADULTS SEEN IN A GERIATRIC ASSESSMENT CLINIC

C.A. Sadowski[1,2], A. Marin[2], *1. Faculty of Pharmacy, University of Alberta, Edmonton, Alberta, Canada, 2. Covenant Health, Edmonton, Alberta, Canada*

Objective: The purpose of this study is to describe medication management problems in a cohort of older adults seen in a geriatric assessment clinic. Methods: A retrospective chart review was conducted through the interdisciplinary seniors clinic at the Misericordia Community Hospital, Edmonton, Alberta. Patients who were seen in the clinic in 2006 or 2007, age 65 years or older, and admitted from a community living setting were included. The data was abstracted by research assistant, entered into an Excel database, and analyzed by SPSS 15.0. Results: The first round of data collection has been completed. Eighty-two patients, 48 female (59%), mean age 81 (SD 7) were included in the first analysis. Three patients (4%) were referred for the primary reason of medication review. Fifty-one patients were identified as having some form of cognitive impairment. Non-adherence was identified in 48 (58%) of patients. Fifty (60%) were identified as having difficulties managing their medications, and 37 (45%) were identified as being “dependent” for medication management. On admission to clinic, 34 (41%) were using calendar packaging. Forty-two patients were receiving supports for medication management, mostly from a spouse (43%). For the specific medication management activities, the following required support: administration (57%), pick up (52%), and ordering refills (33%). Conclusion: Medication management is not recognized as a therapeutic problem by referring family physicians. Older adults have multiple challenges in handling complex medication regimens.

### AIR IN THE PANDORA- A CASE OF SPONTANEOUS NON-TRAUMATIC POSTERIOR GASTRIC PERFORATION

V. Nagaraja, M. Goldschmid, *Internal Medicine, University of Arizona/ University Physicians Health Care at Kino, Tucson, Arizona*

A 75 year old gentleman presented with a sudden onset of respiratory distress. He had exertional shortness of breath and anorexia for a week. He had a past medical history of coronary artery disease, congestive heart failure, atrial fibrillation, peripheral vascular disease, chronic obstructive pulmonary disease, hypertension and type 2 diabetes mellitus. Clinical examination was consistent with respiratory failure, hypovolemic shock and left sided pleural effusion. Abdominal examination was normal. He required intubation, mechanical ventilation and vasopressor support. A supine chest radiograph post-intubation confirmed the left sided pleural effusion. A CT scan of the chest without contrast confirmed the left sided pleural effusion but also revealed pneumoperitoneum. An emergent laparotomy revealed a 1.5 cm posterior gastric ulcer perforation and 1.5 litres of turbid peritoneal fluid was drained. A partial gastrectomy was performed. Stomach biopsy revealed ulceration, necrosis and acute inflammation but a benign stomach mucosa. The patient had a prolonged post-operative hospital course and eventually was transferred to in-patient hospice for comfort care in view of his multiple co-morbidities. Gastric ulcers are commoner in elderly owing to the changes in gastric physiology. Multiple co-morbidities and polypharmacy put them at a higher risk for perforations. Spontaneous non-traumatic posterior gastric perforation is a rare entity. The clinical presentation is less dramatic, more delayed and commonly missed on initial examination due to equivocal or minimal abdominal distension, tenderness and guarding. It is associated with a high mortality. Rapid diagnosis and treatment within the first six hours of perforation is associated with excellent prognosis.

### THE BURDEN OF HEARING LOSS ON THE QUALITY OF LIFE AMONG OLDER ADULTS WITH MEDICARE SUPPLEMENT INSURANCE

K. Hawkins[1], M. Bai[1], R.J. Ozminkowski[3], R.J. Migliori[3], C. Yeh[2], S. Musich[1], *1. Ingenix, Ann Arbor, Michigan, 2. AARP Services Inc., Washington, District of Columbia, 3. UnitedHealth Group Alliances, Ann Arbor, Michigan*

Objective: Estimate the burden of hearing loss on quality of life (QoL) among the elderly with AARP® Medicare Supplement (i.e., Medigap) Insurance underwritten by UnitedHealthcare (or UnitedHealthcare of New York for insureds residing there). Study Design: Data were obtained from insureds who completed the Health Update Survey (HUS). The HUS contained questions on demographics, comorbid conditions, and the Veterans RAND 12-item health status instrument (the VR-12), which was derived from the Short Form 12-item instrument. The HUS was mailed to a random sample of 15,000 insureds from 10 states in 2008. Survey respondents were divided into those with and without hearing loss based on their responses to a survey question. Multiple regression analyses were conducted to estimate the impact hearing loss had on physical and mental health aspects of QoL, while controlling for patient demographics and comorbid conditions. The QoL metrics included the physical (PCS) and mental component scores (MCS) obtained from the VR-12 instrument. Population Studied: Of the 5,515 respondents to the survey, a 37% survey response rate, 10.4% indicated hearing loss. Principle Findings: Those with hearing loss averaged significantly lower PCS (-3.25, p<0.0001) and MCS (-3.23, p<0.0001) scores, compared to those who indicated no hearing loss. Conclusions: The negative impact of hearing loss on QoL exceeded the burden of common comorbidities like diabetes, cancer, and cardiovascular conditions. Implications for Policy: Doctors should screen for hearing loss among elderly patients, and interventions to treat it when found should be applied.

### SLEEP DISTURBANCES AND ADVERSE DRIVING EVENTS IN A COHORT OF ACTIVE OLDER DRIVERS

C.A. Fragoso[1,2], K. Araujo[1], P.H. Van Ness[1], R.A. Marottoli[1,2], *1. Yale University, New Haven, Connecticut, 2. VA Connecticut, West Haven, Connecticut*

STUDY OBJECTIVE: To evaluate the association between sleep disturbances and subsequent adverse driving events, among active older drivers. METHODS: We evaluated 430 older persons, mean age of 78.5 years, who drove at least once-a-week. Baseline measures included self-reported driving patterns and sleep questionnaires, namely the Insomnia Severity Index (ISI), Epworth Sleepiness Scale (ESS), and Sleep Apnea Clinical Score (SACS). The primary outcome was an adverse driving event, based on self-report and driving records, and categorized as a crash or traffic-infraction (composite-I), or as a crash, traffic-infraction, near-crash, or getting lost (composite-II). RESULTS: Participants reported driving a median of 17.0 miles/day, with 96.7% (416/430) driving daily or every-other-day. Although 26.0% (112/430) had insomnia (ISI>/=8), 19.3% (83/430) had daytime drowsiness (ESS>/=10), and 19.9% (84/422) had a high sleep apnea risk (SACS>15), the median scores for the ISI, ESS, and SACS were normal at 3.0, 6.0, and 8.0, respectively, and drowsy-driving was reported by only 5.1%. Over a period of up to 2-years, 24.9% (104/418) and 51.4% (215/418) of participants had a composite-I and -II driving event, respectively. In unadjusted and adjusted multivariable models, insomnia, daytime drowsiness, and high sleep apnea risk were not associated with a composite-I or –II driving event. CONCLUSION: In active older drivers, sleep disturbances are mild and not associated with adverse driving events. Accordingly, and because older persons are known to self-regulate their driving practices, future studies should evaluate whether sleep disturbances are more important as a mechanism that underlies driving cessation, rather than compromising driving safety.

## SESSION 205 (SYMPOSIUM)

### HIP FRACTURES IN THE VETERANS HEALTH ADMINISTRATION (VHA): LESSONS FROM AN INTEGRATED NATIONAL HEALTHCARE SYSTEM

Chair: *R.R. Campbell, COE Maximizing Rehabilitation Outcomes, Tampa, Florida, VISN 8 Patient Safety of Inquiry, Tampa, Florida*
Co-Chair: *G. Powell-Cope, COE Maximizing Rehabilitation Outcomes, Tampa, Florida*
Discussant: *T. Bulat, VISN 8 Patient Safety of Inquiry, Tampa, Florida*

This symposium will discuss patient safety research conducted in the Veterans Health Administration on hip fractures over the past decade. Starting with a view from the developer of the VHA Injury and Adverse Surveillance System, hip fractures will be discussed within the context of a systems approach to measuring injuries and adverse events. Two presentations will be made by two clinicians on patient safety programs and on research using leading edge engineering methods in VHA nursing homes aimed at reducing the burden of hip fractures. Two presentations from health services researchers will discuss the implications of VHA national research on hip fractures and one year all-cause mortality in veterans treated both within the VHA and by the Medicare program. Additionally, an overview of leading edge studies of hip fracture readmission rates and medication profiles of long-stay nursing home residents will be presented by a health economist. VHA research from a multi-disciplinary team will be presented to demonstrate the breadth and depth of patient safety initiatives aimed at reducing the burden of hip fractures in veterans. Special emphasis will be placed on studies conducted in the long term care setting. Because the VHA is a large national horizontally and vertically integrated managed care system, the research findings from the VHA on hip fractures have the potential to inform programs and initiatives in the non-VHA care setting aimed at reducing the burden of hip fractures in the elderly

### AN OVERVIEW OF THE VHA INJURY AND ADVERSE EVENT SURVEILLANCE SYSTEM

R.R. Campbell[1,3], D. French[2], W.A. Lapcevic[1], A.M. Spehar[1], G. Powell-Cope[1], *1. COE Maximizing Rehabilitation Outcomes, Tampa, Florida, 2. VA Center of Excellence on Implementing Evidence, Indianapolis, Indiana, 3. VISN 8 Patient Safety Center of Inquiry, Tampa, Florida*

The purpose of this session is to describe the development and implementation of the VHA Injury and Adverse Event Surveillance System. This system was developed nearly a decade ago by the author at the VISN 8 Patient Safety Center using VHA administrative datasets to track and trend the incidence and costs associated with injury and adverse event hospitalizations in the VHA. The system tracks hospitalizations for admissions with primary admitting diagnoses associated with the AHRQ Clinical Classification System classes 225 through 244. These injuries and adverse events include fractures, traumatic brain injuries, other injuries, iatrogenic complications of healthcare, and poisonings and toxicities associated with medications and other substances. It provides a comprehensive means of tracking the burden of injury hospitalizations in the VHA. Its uses in current patient safety initiatives, to include hip fracture injury mitigation activities, will be described.

### TEMPORAL TRENDS IN INCIDENCE OF HIP FRACTURES IN VA COMMUNITY LIVING CENTERS (CLCS)

T. Bulat[2], R.R. Campbell[1,2], G. Powell-Cope[1], *1. COE Maximizing Rehabilitation Outcomes, Tampa, Florida, 2. VISN 8 Patient Safety Center of Inquiry, Tampa, Florida*

Purpose: To determine whether VA national patient safety initiatives (National Falls Toolkit) have impacted the incidence of hip fractures in VA community living centers (CLC). Methods: The data were extracted from the hospital discharge datasets for FY 2000 - 2008. Fractures were identified using ICD-9-CM diagnosis codes (800-829).The rate of hip fractures per bed days of care (BDOC) was calculated for each year.

Results: Overall, VA hospital hip fracture discharges (from all sources) have been decreasing over time. The number of hip fractures in CLCs have decreased 28% and the rate of hip fractures/BDOC by 19%. There was a distinct change in the rate in FY 2005 and this downward trend has persisted relative to pre-FY 2005 rates. Implications: There seems to be a temporal relationship between the patient safety initiatives implementation in FY 2005 and a subsequent improvement in the trends for hip fractures in VA CLCs.

### PREDICTING INJURIOUS FALLS IN NURSING HOMES USING SOCIO-TECHNICAL PROBABILISTIC RISK ASSESSMENT

G. Powell-Cope[1], R.R. Campbell[1,3], B. Hahm[1], I. Joseph[2,1], T. Bulat[3], J. Westphal[4], *1. COE Maximizing Rehabilitation Outcomes, Tampa, Florida, 2. James A Haley Hospital, Tampa, Florida, 3. VISN 8 Patient Safety Center of Inquiry, Tampa, Florida, 4. Outcome Engineering, Plano, Texas*

Purpose: This study applied socio-technical probabilistic risk assessment (used in high reliability industries) to prioritize risks for serious injurious falls in nursing homes. Methods: One and two day meetings were conducted with 26 clinical and nonclinical staff from four facilities. Staff identified and assigned probabilities to provider, resident, and equipment failures. Results: The greatest path of risk was for residents with impaired mobility and high fragility (e.g. osteoporosis) who engaged in unassisted wheelchair transfers to and from the bed and toilet, when the wheelchair locks were not engaged and protective measures were not in place (e.g. hip protectors). Implications: As modeled, injurious falls could be reduced by 26% by modest improvement in alarms response time, automatic break locks on 90% of wheelchairs, a high reliable wheelchair maintenance process, and a 10% improvement in transfer techniques. Models will be used to develop cognitive tools to assist clinicians in making evidence-based decisions about fall injury prevention.

### HIP FRACTURES: LESSONS FROM THE VHA FOR MEDICARE PROGRAMS AND POLICIES

D. French[2], R.R. Campbell[1,4], A.M. Spehar[1,4], W.A. Lapcevic[1], E. Bass[3], *1. COE Maximizing Rehabilitation Outcomes, Tampa, Florida, 2. VA Center of Excellence on Implementing Evidence, Indianapolis, Indiana, 3. Congressional Budget Office, Washington DC, District of Columbia, 4. VISN 8 Patient Safety Center of Inquiry, Tampa, Florida*

The purpose of this presentation is to present several published studies on hip fractures in the VHA. These studies will discuss the burden of hip fracture injuries in the long term care setting in the VHA, problematic medication profiles and attendant risks for hip fractures, hospital readmissions associated with hip fractures, and other leading edge issues dealing with financial incentives that may impact hip fracture injury mitigation programs. The presenter is a health economist who will discuss published research at the national level with an emphasis on hip fractures occuring in the VHA long term care setting.

### ALL-CAUSE MORTALITY RATES OF HIP FRACTURES TREATED IN THE VHA: DO THEY DIFFER FROM MEDICARE FACILITIES?

W.A. Lapcevic[1], D. French[2], R.R. Campbell[1,3], E. Bass[4], *1. COE Maximizing Rehabilitation Outcomes, Tampa, Florida, 2. VA Center of Excellence on Implementing Evidence, Indianapolis, Indiana, 3. VISN 8 Patient Safety Center of Inquiry, Tampa, Florida, 4. Congressional Budget Office, Washington DC, District of Columbia*

PURPOSE: To estimate the 1-year all-cause mortality rates for hip fracture (HFx) patients hospitalized at Veterans Health Administration (VHA) facilities and compare with previous published mortality rates for veterans treated in Medicare facilities. METHODS: In total, 7 years of VHA discharge data on HFxs for 12,539 patients age 65 and older were combined with national death registry data. We performed a 1-year survival analysis using the Cox proportional hazard method. RESULTS: The adjusted rates for veterans treated in the VHA (30 days=9.3%, 90 days=17.5%, 180 days=23.3%, 365 days=29.8%) were similar to veterans treated in Medicare facilities (30 days=8.9%, 90 days=15.6%, 180 days=21.8%, 365 days=29.9%). For veterans treated for a HFx in Medicare facilities, the average length of stay was 7 days compared to an average length of stay of 14 days in the VHA

## SESSION 210 (PAPER)

## IDENTIFYING RISKS OF FRAILTY AND NURSING HOME PLACEMENT

### THE PSYCHOMETRIC PROPERTIES OF THREE SELF-REPORT SCREENING INSTRUMENTS FOR IDENTIFYING FRAIL OLDER PEOPLE IN THE COMMUNITY

S. Metzelthin[1,2], R. Daniels[2,1], L. de Witte[2,1], W. van den Heuvel[1,3], G.I. Kempen[1], *1. Maastricht University, Maastricht, Limburg, Netherlands, 2. Zuyd University of Applied Sciences, Heerlen, Limburg, Netherlands, 3. University Medical Centre Groningen, Groningen, Groningen, Netherlands*

Background: Frailty is highly prevalent in older people. Its serious consequences, such as disability, are considered to be a public health problem. With regard to disability prevention, valid screening instruments are needed to identify frail older people in time. The aim of this study was to evaluate and compare the psychometric properties of three frailty instruments: the Groningen Frailty Indicator (GFI), the Tilburg Frailty Indicator (TFI) and the Sherbrooke Postal Questionnaire (SPQ). For validation purposes a disability questionnaire (GARS) was added. Methods: In The Netherlands a questionnaire was sent to 687 community-dwelling older people (≥70 years). Agreement between screening instruments, internal consistency, and construct validity were evaluated and compared. Results: The response rate was 77%. Frailty prevalence estimates ranged from 40% to 59%. Highest agreement was found between GFI and TFI (Cohen's kappa=0.74). Cronbach's alpha for GFI, TFI and SPQ was 0.73, 0.79 and 0.26, respectively. Scores on frailty instruments correlated significantly with each other (GFI–TFI, r=0.87; GFI–SPQ, r=0.47; TFI–SPQ, r=0.42) and with the GARS (GFI–GARS, r=0.57; TFI–GARS, r=0.61; SPQ–GARS, r=0.46). GFI and TFI scores were, as expected, significantly related to age, sex, education and income. Conclusions: GFI and TFI showed high internal consistency and construct validity in contrast to SPQ. Based on these findings it is not yet possible to conclude whether GFI or TFI should be preferred; data on the predictive values of both instruments are needed. The SPQ seems less appropriate for postal screening of frailty among community-dwelling older people.

### FRAILTY AS A PRECLINICAL STAGE OF THE DISABLEMENT PROCESS IN LATER LIFE

M.E. Bowen[1], M. Rowe[1,2], *1. HSR&D/RR&D Center of Excellence, Veterans Health Administration, Tampa, Florida, 2. University of Florida, Gainesville, Florida*

Purpose: To examine the relationship between frailty and the disablement process. Design and Methods: Eight years of longitudinal data from the Health and Retirement Study (HRS; 1998-2006), a nationally representative sample of community-dwelling adults age 50 and older in 1998 (N=11,491) were used. Nonlinear multi-level models used frailty (a fall, difficulty getting up from a chair, effort, exhaustion, physical inactivity, and being underweight, overweight, or obese) to predict disabilities in mobility, functioning (Instrumental Activities of Daily Living; IADL), and self-care (Activities of Daily Living; ADL). The roles of other confounding factors including demographics (age, sex, race/ethnicity, cohort, marital status), socioeconomic conditions (education, income, and wealth), health behaviors (smoking, drinking alcohol), and health conditions (high blood pressure, diabetes, stroke, heart condition, arthritis, and depressive symptoms) were also evaluated in multilevel models. Results: A fall, difficulties getting up from a chair, effort and exhaustion reports were significantly associated with mobility, IADL, and ADL disability. Underweight respondents had an increased risk for disabilities in mobility (1.16; p≤0.001), IADL (1.30; p≤0.001), and ADL (1.31; p≤0.001) and obese respondents had an increased risk for disabilities in mobility (1.40; p≤0.001) and ADL (1.16; p≤0.01). However, being overweight (0.76; p≤0.001) or obese (0.78; p≤0.001) was associated with a decreased risk for disabilities in IADL and there was no relationship between being overweight and disabilities in ADL. Implication: Overall, results from this nationally representative longitudinal study suggest that frailty may be a preclinical stage in the disablement process.

### EXPLAINING TRANSFERS FROM HOME AND COMMUNITY BASED WAIVER PROGRAM TO NURSING HOME: CAN PATIENTS STAY AT HOME?

C.W. Given[1], A. Sikorskii[2], S.L. Spoelstra[2], M. You[2], *1. College of Human Medicine, Michigan State University, East Lansing, Michigan, 2. Michigan State University, East Lansing, Michigan*

The ability of 8,161 medically and economically vulnerable older persons to remain at home compared to transferring to a nursing home (NH) is examined in a Home and Community Based Waiver (HCBW) program between 2003 and 2007. Comparisons of those who remained at home (4344) and NH transfers (3817) were performed on: sociodemographics, physical function, cognitive status, caregiver support, living arrangement, and service utilization. Data were obtained from the Minimum Data Set-Home Care and Medicaid claims. Generalized linear models were used to compare remaining at home to NH transfers. Patients remained at home for 38.8 months compared, to 27.6 months at home for NH transfers. Sex and race/ethnicity did not influence NH transfer, however Caucasians had a higher rate of NH transfer. Patients 76 years of age or older (74%), with one or more deterioration in activity of daily living (37%), with an increase in falls (23%), who wanted a change in living arrangement (12%), and had no increases in home care services (49%) were more likely to transfer to NH. Comorbid conditions and frailty measures (incontinence, vision, hearing, and weight loss) did not predicted NH transfer. Those who deteriorated in ADLs, are dissatisfied with their living arrangements, and have no increase in waiver program services are at highest risk of a transfer to NH. Thus, using known predictors to identifying those at risk of transfer to NH, modifying the plan of care to address these risks, and increasing home services may delay NH transfer in this population.

### PREDICTORS FOR NURSING HOME PLACEMENT AND DEATH IN COMMUNITY-BASED OLDER ADULTS WITH DISABILITY

M.R. Tomita, P. Suryakumar, S. Nochajski, B. Naughton, *Rehabiliatation Scinece, University at Buffalo, Buffalo, New York*

This study aimed to identify predictors for nursing home placement (N) and death (D) that may occur within a year in community-based older adults with functional deficit. A baseline assessment in participants' home and a one year follow-up phone interview were made by health care professionals. The data were collected for a period of five years. All participants were referred by a county senior services department or skilled nursing home facilities in Western New York. One year after the baseline assessment, 63.4% of 358 participants were living in their home (L), 8.7% moved to a nursing home, and 27.9% died. Binary logistic regression analyses were used with a stepwise entry method. The results showed that the prediction accuracies for N, D, and L were 76.7%, 71.0%, and 92.5-98.2%, respectively. The major common predictors for D and N were: having a diagnosis of Alzheimer's disease, a higher physical disability level, a lower Body Mass Index, and more sick days in the past six months. Unique predictors for N were: lower levels of Mini Mental State Exam scores, grip strength, and function for transfer. Those for D were: having a diagnosis of heart disease, lower function for locomotion, and being unable to take own medication, and not-married. The result confirms many past findings being applicable to this vulnerable population. The unique finding is that lower statuses of specific activities of daily living (ADL) and Instrumental ADL (IADL) are strong predictors for N or D within a year, therefore require particular attention.

# SESSION 215 (PAPER)

## ISSUES IN RESEARCH METHODS

### CHALLENGES IN RESEARCH RECRUITMENT OF HOSPITALIZED OLDER ADULTS WITH COGNITIVE IMPAIRMENT

K.B. Hirschman[1,2,3], C. Bradway[1,5,3], K.H. Bowles[1,2,3], B.O. Ha[1], T.V. Williams[1], M.D. Naylor[1,2,4], *1. University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania, 2. NewCourtland Center for Transitions and Health, Philadelphia, Pennsylvania, 3. Insitute on Aging, University of Pennsylvania, Philadelphia, Pennsylvania, 4. Leonard Davis Institute of Health Economics, Philadelphia, Pennsylvania, 5. Center for Integrative Science in Aging, Philadelphia, Pennsylvania*

The objectives of this study were to screen and enroll cognitively impaired hospitalized older adults and their family caregivers into a clinical trial to test nursing interventions. Adults age 65 and older, non-terminal, living within 30 miles radius of admitting hospital and who were planning to return home were eligible to be screened. Cognitive impairment was assessed using two validated measures: the Six-Item Screen (SIS) and the CLOX1, unprompted clock drawing task. Patients with a diagnosis of dementia were automatically eligible to enroll. Of the 16,663 admissions from 4/2006 to 12/2009, 9374 charts were reviewed and 5164 met inclusion criteria. Within this sample, 234 (4.5%) patients had a diagnosis of dementia and an additional 4930 patients were approached to be screened for cognitive impairment. Among patients screened for CI (3549/4930, 72.0%), 44.7% (n=1588) had deficits in orientation or recall (SIS) or executive function (CLOX1). Among those eligible to participate (either screening for cognitive impairment or history of dementia), 536 patient-caregiver dyads enrolled (536/1822; 29.4%). Common reasons for refusal included the patient or the caregiver not willing to enroll, being unable to reach the family caregiver before the patient's discharge from the hospital and lack of interest in research. Among those who enrolled, delirium was present in 24% of patients. Lower Mini Mental State Examination score was highly associated with delirium, functional deficits, patient depression, and higher caregiver burden. Implications for recruitment in the hospital setting and retention of patients with cognitive impairment and their family caregivers will be discussed.

### OVERCOMING RECRUITMENT CHALLENGES IN OLDER ADULT PUBLIC HOUSING RESIDENTS: LESSONS LEARNED

A. Simning[1], E. van Wijngaarden[1], Y. Conwell[2], *1. University of Rochester School of Medicine and Dentistry, Department of Community and Preventive Medicine, Rochester, New York, 2. University of Rochester School of Medicine and Dentistry, Department of Psychiatry, Rochester, New York*

Background: Conducting research within urban communities and achieving recruitment goals can be challenging. A variety of approaches are needed to overcome recruitment barriers, which include mistrust, mobility issues, stigma, and illiteracy. We will share lessons learned from a study examining mental health among older adult public housing residents. Setting: Participants were recruited from four older adult public housing high-rises maintained by the Rochester Housing Authority in Rochester, NY. Methods: We conducted a two-stage cross-sectional study. In the first stage, high-rise residents completed a health questionnaire. The second stage consisted of a 1-2 hour psychiatric research interview of English-speaking residents aged 60 years and older. To enhance recruitment, we partnered with a community aging services agency, conducted a series of on-site educational booths prior to recruiting, had on-site recruitment booths, mailed a series of letters, provided financial incentives, and administered the interviews in residents' apartments. Results: Prior to recruitment, on-site educational booths enabled us to become acquainted with the residents, many of which helped with recruitment once the study commenced. Providing cash incentives at the on-site recruitment booths resulted in many referrals, and interviewing in residents' apartments also facilitated and increased participation. Mailings were largely ineffective because most residents preferred to participate in person. Conclusions: We overcame considerable recruitment barriers through a multipronged approach. To optimize recruitment of urban older adults, we recommend developing a relationship with the study population before initiating a research project, recruiting in-person, providing immediate incentives, and not requiring participants to travel to study sites.

### DEVELOPMENT AND PSYCHOMETRIC EVALUATION OF NURSE-PATIENT RELATIONSHIP SCALES IN CHRONIC CARE

V.M. Boscart, D. Pringle, K.S. McGilton, E. Peter, F. Wynn, *Bloomberg Faculty of Nursing, University of Toronto, Toronto, Ontario, Canada*

Quality of life and well-being of patients living in chronic care is determined largely by the relationships they have with nursing personnel. Given the importance of these relationships, there is an absence of valid and reliable scales to assess these relationships. The purpose of this study was to develop and test a measure to determine what qualities of relationships between patients and nursing personnel were most important and experienced. A conceptual framework based on the Humanistic Nursing Theory served as a foundation to develop two scales; the Humanistic Relationship Importance Scale (HRIS) and the Humanistic Relationship Experience Scale (HRES). Sixty-nine items were developed and tested for content validation and initial validity and reliability (n=40). Subsequently, 45 items were deleted. Next, the 24-item scales were completed by 249 patients in five facilities and the results subjected to a principal axis analysis. The HRIS presented a five factor solution and the HRES a one factor solution. The HRIS had a Cronbach′s alpha of .87 indicating strong internal reliability. The HRES had a Cronbach′s alpha of .98 suggesting redundancy of items. Relational availability was rated as the most important factor in the nurse-patient relationship although all factors were important to patients. The mean score of the HRES indicated that patients experience a moderate level of humanistic connection in terms of nurses who generally care for them. Findings of this study have contributed to a better understanding of the nurse-patient relationship, and support the care, research, and theoretical knowledge of relationships in these environments.

### METHODOLOGICAL CHALLENGES OF CONDUCTING AN ON-LINE, ELECTRONIC DELPHI SURVEY WITH AGING AND PHYSICAL ACTIVITY RESEARCH EXPERTS

K.H. Leith[1], S.L. Hughes[2], G. Moni[4], D.X. Marquez[2], P. Desai[2], H. Nguyen[4], D. Jones[3], *1. University of South Carolina, Columbia, South Carolina, 2. University of Illinois at Chicago, Chicago, Illinois, 3. West Virginia University, Morgantown, West Virginia, 4. University of Washington, Seattle, Washington*

Background: The purpose of this Delphi Survey was to query aging and physical activity (PA) experts about knowledge gaps and to determine the "state-of-the-art" in the relevant literature on health and functional outcomes. This presentation describes the methodological challenges of conducting the study. Theoretical Framework & Methods: The study was initiated as a Delphi Survey, an iterative, multi-stage process of group interaction to achieve consensus. An on-line survey was created in SurveyMonkey and pilot-tested in Spring 2009. Phase 1 data were collected in Fall 2009. Respondents had three weeks for completion; reminders were sent at Weeks 2 and 3. Of 402 invitations sent, 381 were received. Results: Of the 381 responses received, 348 were "appropriate" contacts. Of those, 181 (52%) responded but only 131 (38%) partially or fully completed the survey. Respondents who chose not to complete or partially completed the survey indicated that the survey took too long to complete and sought to elicit information too complex to address in this format. Conclusion & Implications for Practice: One major challenge was identifying and eliciting responses from "appropriate" respondents, i.e., those who were experts in aging and PA and recognized the study as legitimate. A second and third were the chosen timeframe for data collection (e.g., summer break), and the method of data collection (i.e., wrong e-mail addresses, spam filters). Based on respondents' feedback, conducting Phase 2 was not necessary. Phase 1 findings will be useful in developing a research agenda of aging and PA topics ranked according to scientific importance.

## SESSION 220 (SYMPOSIUM)

### NURSING CARE OF OLDER ADULTS INTEREST GROUP SYMPOSIUM: RESEARCH AND PRACTICE INNOVATIONS IN TRANSITIONS OF CARE

Chair: *H.M. Young, UC Davis Health System, Betty Irene Moore School of Nursing, Sacramento, California*
Co-Chair: *C. Beck, University of Arkansas for Medical Sciences, DW Reynolds Center on Aging, Little Rock, Arkansas*
Discussant: *K. Gretebeck, University of Michigan, School of Nursing, Ann Arbor, Michigan*

Older adults experience many transitions, including transitions in relationships, living environments, health, and health care settings. Nurses can facilitate these transitions and contribute to optimal outcomes for the older adult. The purpose of this presentation is to provide an overview of key aspects of transition theory and recent theoretical, research and practice developments, with application to gerontological nursing. Specifically, the presentations will discuss 1) the process of transitions, indicators of healthy transition processes, transition outcomes, and the risks inherent for older adults experiencing multiple simultaneous transitions; 2) how family caregivers of cognitively impaired older adults may benefit from interventions aimed at improving care management that would impact repeated hospitalizations; and 3) barriers and facilitators to change and other factors that may impact interventions focused on adoption of evidence-based practices and care of older adults with cancer.

### TRANSITION THEORY: APPLICATION TO GERONTOLOGICAL NURSING PRACTICE, EDUCATION, AND RESEARCH

K. Schumacher, *UNMC College of Nursing, Omaha, Nebraska*

Transition theory is central to the nursing knowledge base, with a high degree of relevance for gerontological nursing. Older adults experience many transitions, including transitions in relationships, living environments, health, and health care settings. Nurses can facilitate these transitions and contribute to optimal outcomes for the older adult. The purpose of this presentation is to provide an overview of key aspects of transition theory, with application to gerontological nursing. Meleis' and Brooten's ground-breaking work in transition theory as well as recent theoretical developments will be highlighted. Emphasis will be on transition as a process, critical periods and turning points in transitions, indicators of healthy transition processes, transition outcomes, and the risks inherent for older adults experiencing multiple simultaneous transitions. The presentation will conclude by envisioning innovative future directions for the application of transition theory in nursing research, education, and practice.

### ENHANCING CARE COORDINATION FOR COGNITIVELY IMPAIRED OLDER ADULTS AND THEIR FAMILY CAREGIVERS

M.D. Naylor, K.B. Hirschman, A.L. Hanlon, *University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania*

Cognitively impaired hospitalized older adults typically experience complicated index hospitalizations, increased hospital readmissions and higher health care costs. Available evidence suggests that this population and their family caregivers may benefit from interventions aimed at improving care management. Using a prospective cross-sectional design study, hospitalized older adults with deficits in orientation, recall or executive function or who had a diagnosis of dementia and who had a family caregiver were enrolled during an acute hospitalization. Patient-caregiver dyads received one of three nursing interventions: 1) augmented standard of care provided during the index hospitalization; 2) resource nurse care received during the index hospitalization, and 3) advanced practice nurse care (Transitional Care Model) received during the hospitalization and up to three months post-discharge. Findings on patient and caregiver outcomes for each of these intervention groups will be presented for the first 150 matched (using propensity score adjustment) patient-caregiver dyads will be presented.

### IMPROVING PAIN MANAGEMENT AT THE END OF LIFE: BARRIERS AND FACILITATORS TO A CHANGE INTERVENTION

K. Herr, *University of Iowa, College of Nursing, Iowa City, Iowa*

Dr. Herr will overview the findings from an NCI-funded study “Cancer Pain in Elders: Improving Evidence-Based Practices in Hospices”. Following a year long intervention, data were gathered regarding barriers and facilitators to change and other factors that may impact interventions focused on adoption of evidence-based practices. This paper will highlight unforeseen issues that contribute to the effectiveness of a translating research into practice intervention in the setting of hospice and care of older adults.

## SESSION 225 (SYMPOSIUM)

### PERSONALITY TRAITS: PATHWAYS TO OLDER ADULTS’ FUNCTIONAL CAPACITY, AFFECT, AND SUBJECTIVE WELLBEING

Chair: *P.S. Fry, Graduate Psychology, Trinity Western University, Langley, British Columbia, Canada*
Discussant: *M.K. Diehl, Colorado State University, Fort Collins, Colorado*

Hitherto, much of the experimental and survey research on the relationship of personality traits to health, emotional and social well being and self-enhancement has been conducted on target samples of youth and adults. More recently, however, the emerging trends in the gerontological research are that personality traits play an equally important role in determining older adults’ behavioral characteristics, cognitive views and motivations for life. The papers to be presented in the present symposium aim to address these issues further and to highlight the newly emerging trends regarding the role of personality traits in relation to older individuals’ functional capacity, sense of self-efficacy/ positive and negative affect, and their will to live or die. For example, Martin et al.’s research presents findings to confirm that various personality traits, as defined by the 5-factor personality traits, serve as moderators of the old and very old adults’ functional capacity and positive and negative affects. Fry & Debats’ longitudinal investigation shows that, additional to the 5-factor personality traits, other personality traits of high levels of self- and other-directed perfectionism are early predictors of negative affect. Their research supports the hypothesis that perfectionism is strongly associated with mortality. Jopp et al.’s research directs attention to the issue of how traits of self-efficacy, optimism, or the will to live contribute to a substantial variance in older adults’ life satisfactions. Collectively, these research papers suggest the need for further work focusing on the theoretical and empirical implications of the role of personality traits in old age.

### PERSONALITY TRAITS AND PSYCHOLOGICAL STRENGTHS IN OLD AND VERY OLD AGE: THEIR CONTRIBUTION TO LIFE SATISFACTION

D.S. Jopp[1], D. Wozniak[2], C. Rott[2], F. Oswald[3], *1. Psychology, Fordham University, Bronx, New York, 2. Heidelberg University, Heidelberg, Germany, 3. Frankfurt University, Frankfurt, Germany*

We investigated whether psychological strengths and personality aspects such as self-efficacy or optimism gain importance for life satisfaction with advancing age relative to resources such as health and social factors. Community-dwelling individuals aged 65 to 94 years (N=356) rated their life satisfaction, resources (income, health, network), and psychological strengths/personality (self-efficacy, optimistic outlook, meaning, will to live). Mean levels of resources, psychological strengths, and life satisfaction were lower in the fourth compared to the third age. In the total sample, psychological strengths and health explained substantial amounts of variance in life satisfaction, but sociodemographic and social indicators made no independent contribution. In the young-old, health and psychological strengths were equally strong predictors; psychological strengths were the only significant predictor block and explained substantially more variance in the old-old. Findings suggest that health becomes less important for life satisfaction with advancing age while psychological strengths gain in importance despite declining mean levels.

### PERSONALITY, FUNCTIONAL CAPACITY, AND WELL-BEING AMONG CENTENARIANS

P. Martin[1], J. Cho[1], M. MacDonald[2], L. Poon[3], *1. Iowa State University, Ames, Iowa, 2. Kansas State University, Manhattan, Kansas, 3. University of Georgia, Athens, Georgia*

It is now well established that personality traits play an important role in the well-being of old and very old adults. What has received very little attention is whether these traits predict well-being outcomes independently of functional limitations and whether personality traits serve as moderators in the functional capacity – well being relationship. Using data from the Georgia Centenarian Study, we assessed activities of daily living, personality traits, and positive and negative affect among persons 98 years and older (N=234). Multiple regression analyses were computed including demographic variables, functional capacity, and personality traits as predictors of affect. Results indicate that functional capacity ($\beta = .22, p < .01$), Extraversion ($\beta = .34, p < .001$), Neuroticism ($\beta = -.22, p < .01$), Openness ($\beta = .24, p < .01$), and Conscientiousness ($\beta = .32, p < .01$) all predicted positive affect, whereas Extraversion ($\beta = -.26, p < .001$), Neuroticism ($\beta = .48, p < .001$), Agreeableness ($\beta = -.20, p < .01$), and Conscientiousness ($\beta = -.18, p < .05$) predicted negative affect. Openness served as a moderator suggesting that centenarians’ positive affect score was more likely to be influenced by functional capacity if they were open-minded.

### PERFECTIONISM, CONSCIENTIOUSNESS AND NEUROTICISM TRAITS AS PREDICTORS OF WELL-BEING IN OLD AGE

P.S. Fry, *Graduate Psychology, Trinity Western University, Langley, British Columbia, Canada*

The relationship between perfectionism as a personality trait and general happiness, positive and negative affect and longevity versus mortality were explored in a longitudinal study of 450 community-based older adults. Following baseline assessments of happiness, affect, and personality traits of perfectionism and other five-factor traits of conscientiousness, extraversion and neuroticism etc., findings from the Cox regression analysis showed that risk of death is significantly greater for very high scorers in perfectionism, compared to low scorers. As a function of high scores in perfectionism and neuroticism at baseline, median happiness levels were significantly lower for decedents compared to survivors. As a function of high scores in conscientiousness and extraversion, happiness levels were higher in survivors. Results suggest the protective and positive influence of personality traits of conscientiousness and extraversion on well-being, and the negative influence of perfectionism and neuroticism. Implications of the impact of personality traits on well-being are discussed.

## SESSION 230 (SYMPOSIUM)

### DIGITAL INCLUSION FOR SENIORS: TRAINING, INTERNET ACCESS, AND SOCIAL ENGAGEMENT

Chair: *B. Harootyan, Senior Service America, Silver Spring, Maryland*
Discussant: *S. Fox, Pew Research Center's Internet & American Life Project, Washington, District of Columbia*

Computer illiteracy is most prevalent among persons aged 65+ and those with low educational attainment. Pew Internet Project national surveys indicate that 74% of adults aged 18+ use the internet, compared to only 38% of those aged 65+ and 39% of adults without a high school diploma. Older adults suffer most from the digital divide, yet computer literacy is increasingly important in everyone's personal and work lives. Internet-based information and communication is synonymous with empowerment. It also provides opportunities for social engagement in diverse "communities," including family and friends. This symposium presents information about applied research designed to reduce the digital divide among elders. Czaja reports on older workers' attitudes toward communication technologies, their preferences for specific types of computer instruction, and training that helps older adults adapt to workplace technologies. The importance of seniors as peer coaches for older learners is discussed by Harootyan and Slobig. Attendees will learn about the instrumental and psychosocial outcomes of a computer/internet training program serving over 7,000 seniors at more than 150 public coaching sites. Cotten presents results from a randomized controlled trial for training older adults to use communication technologies in assisted and independent living communities, including measures of quality of life. The role of computer access and the internet to promote social engagement among very old adults is reviewed by Cutler. Attendees will learn how touch-screen technologies allow easy internet access for email, information retrieval and entertainment for older retirees in an assisted living residence and a NORC.

### THE IMPLICATIONS OF WORKPLACE TECHNOLOGIES FOR OLDER WORKERS

S. Czaja, C. Lee, *Psychiatry and behavioral sciences, university of miami miller school of medicine, Miami, Florida*

The number of workers aged 55+ will increase significantly in the next few decades. This paper will present findings, from focus groups and surveys, regarding use of technologies in the workplace and perceptions regarding the impact of these technologies on work processes and outcomes from a diverse sample of older adults. Thirty-seven persons aged 50-80 years participated in the focus groups and completed a job history, computer experience, computer attitude questionnaires. The majority of participants reported being comfortable using technology at work and perceived that technology helps them work more efficiently and productively, facilitates communication with colleagues and access job information. However, the participants also indicated that technology often results in information overload, makes their more stressful, and results in a loss of social interaction. Further, many participants indicated they did not receive adequate training to use new technologies. Findings regarding preferred characteristics of "ideal jobs" are also discussed.

### PROMOTING DIGITAL INCLUSION: PEER COACHES AND SENIOR LEARNERS

B. Harootyan, F. Slobig, *Senior Service America, Silver Spring, Maryland*

To help bridge the digital divide among seniors, Senior Service America created the Digital Inclusion Initiative (DII) through its Senior Community Service Employment Program (Title V: OAA). The DII involves 60 SSAI subgrantees with >150 public sites (libraries, senior centers, service agencies) that provide tutorial sessions overseen by >135 SCSEP participants who were trained to be "peer coaches." They assist other seniors to use the self-paced Generations on Line tutorial to master each step of computer/internet literacy. Average age of the first 2,500 learners: 68; peer coaches: 63. Two-thirds of each group are women. Outcomes include effectiveness of the DII sessions, including peer coaches' perceptions of the most challenging aspects of coaching seniors (e.g., overcoming fears; mistrust of the internet) and what worked best (e.g., repetition, pacing, example). Coaches' and learners' changes in attitudes about and use of computers/internet, self-efficacy, morale, and general well-being are discussed. Individual testimonials are highlighted.

### USING ICTS TO ENHANCE QUALITY OF LIFE AMONG RESIDENTS OF INDEPENDENT AND ASSISTED LIVING COMMUNITIES

S.R. Cotten, *Sociology, UAB, Birmingham, Alabama*

Depression, physical health decline, loneliness, and social isolation are key issues of concern for older adults. With increasing numbers of older adults going into long term care facilities and declines in quality of life as individuals age, we need innovative ways to decrease these negative impacts and to enhance quality of life. Older adults are the least likely to use information and communication technologies (ICTs), yet the potential to help them connect with members of their social networks to enhance social support and quality of life is substantial. Results of a large randomized trial designed to teach older adults in assisted and independent living communities to use ICTs are presented. Details concerning key recruitment strategies, technological modifications, training procedures, and quality of life changes are included.

### THE MOTION PICTURE & TELEVISION FUND'S COMPUTER-ASSISTED SOCIAL ENGAGEMENT PROJECT (CASE): AGING IN PLACE NEED NOT BE HOME ALONE

N.E. Cutler, *Center on Aging, Motion Picture & Televison Fund, Woodland Hills, California*

Aging in place need not be aging in isolation. It's not Home Alone. To combat the negative health and social effects of isolation the Motion Picture & Television Fund is developing the CASE project: Computer-Assisted Social Engagement. CASE hardware/software uses large format touch-screen computers and an elder-friendly Windows desktop so Participants can easily access email (by typing, voice, or video), Internet, music and games, and photos with no prior computer, keyboard, or mouse experience. In Phase I CASE is being installed in the homes of ten 80-year-old entertainment retirees, half aging in place in the Westside Los Angeles entertainment NORC and half on the MPTF assisted living campus. Beyond Participant experiences we are assessing such basic yet critical issues as overall cost, involvement of social workers, internet installation, ongoing technical assistance, family response, and how CASE precipitates Participant demand for additional modes of social engagement.

## SESSION 235 (PAPER)

## DISCHARGING FROM NURSING HOME TO COMMUNITY CARE

### TRANSITIONING FROM NURSING FACILITIES TO HOME: PREDICTORS OF COMMUNITY DISCHARGE

Z.D. Gassoumis, K. Thomas, S. Enguidanos, K. Wilber, *Davis School of Gerontology, University of Southern California, Los Angeles, California*

In recent decades, long-term care research and policy have focused on reducing nursing home placement by providing home and community-based services. Over the last decade, however, policies have also been directed at transitioning patients from nursing homes back to community settings. Despite the strong emphasis on nursing home transition, there has been little research on either the individual predictors of transition or the outcomes of various policies. In response, this paper analyzes the predictors of transitioning to the community using data from the nursing home Minimum Data Set 2.0 (MDS), collected from four California counties between 2001 and 2003. Admission characteristics for 4,635 episodes of care are analyzed using two models: (1) comparing residents who transition to the community within 90 days of admission with those who remain in the nursing home at 90 days; and (2) comparing residents who transition to the community between 91 and 270 days with those who remain in the nursing home at 270 days. Independent variables include predisposing (e.g., sociodemographics), need (e.g., health status), and enabling characteristics (e.g., health insurance, preference to transition). Results indicate that almost all discharges to the community (91%) occurred within the first 90 days. Moreover, enabling characteristics (e.g., preference, having a support person who is positive toward discharge) are strong predictors of community discharge within 90 days but do not predict discharge between 91 and 270 days. Implications are discussed for the allocation of transition-oriented services as well as policy programs such as Money Follows the Person.

### AN ANALYSIS OF BARRIERS TO NURSING HOME DISCHARGE: CREATIVE STRATEGIES TO GOING HOME

E. Kahoe, R. Meador, K. Pillemer, *Human Development, Cornell University, Ithaca, New York*

Deinstitutionalization has become a national priority in the United States, with states seeking cost-savings through “rebalancing” long-term care funding for older adults away from nursing homes. Although many nursing home residents may be candidates for transition to community living, the diverse backgrounds, financial and social resources, and medical needs of this population limit the utility of a one-size-fits-all approach. Understanding the needs of this community and documenting successful strategies to meet these needs are important steps in promoting nursing home discharge. We report on an evaluation of an enhanced discharge planning program that targeted long-term care nursing home residents. Barriers faced by clients during the discharge planning process were gathered from social worker case notes then grouped into three major themes (complex medical conditions, lack of family or social support, and inability to obtain suitable housing) that summarized 22 specific obstacles. Although some client needs — like nutrition or home care services — could be met by existing resources in the community, a surprising number of the barriers fell outside of this range and required the development of new strategies by intervention staff. Barriers were also ranked according to the effect they had on patient discharge, as some were more likely than others to prevent patients from going home. We present case studies from the intervention to illustrate the impact of seemingly minor obstacles and to demonstrate how an enhanced, patient-centered approach can effectively promote nursing home discharge.

### SUCCESSFUL DISCHARGE STRATEGIES FOR MEDICAID NURSING FACILITY RESIDENTS WITH MENTAL HEALTH NEEDS

R.K. Chapin, S. Leedahl, B.A. Baca, L. Hasche, G. Townley, R. Rachlin, J.F. Sergeant, *University of Kansas School of Social Welfare, Lawrence, Kansas*

With two decades of federal grant support, state initiatives to promote discharge of Medicaid residents in nursing facilities (NFs) have generated new knowledge on how to successfully discharge people from NFs to community settings. Yet, little is known about specific strategies required for transitioning Medicaid residents with mental health diagnoses. This study describes the characteristics, patterns, and successful strategies for older NF residents with mental health diagnoses who discharged to the community. Method: Using MDS data from 2005 to 2008 for Kansas, we examined the characteristics and patterns of discharge for 372 older adults with anxiety disorder, bipolar disorder, or schizophrenia who discharged from the NF to a community setting. Through in-depth interviews, NF discharge staff recommended strategies for ensuring successful discharge. Results: The sample was predominately female (78.2%), Caucasian (91.4%), and low income (all Medicaid recipients), with an average age of 77. Many of the residents had multiple nursing home admissions and discharges within the three-year period, yet 43% did remain in the community after their first discharge. In interviews, NF staff identified effective strategies including: (1) utilizing community resources (e.g. community mental health centers, support groups) prior to discharge, (2) consulting mental health professionals, (3) identifying a support person and meaningful social activities, (4) setting goals with residents and family members, and (5) training informal caregivers to manage mental health needs. Implications: This evidence indicates that NFs are successful in discharging residents with mental health needs and highlights specific community supports needed in planning for the discharge.

## SESSION 240 (SYMPOSIUM)

### EXPLORING THE FOURTH AGE: PERSPECTIVES FROM THE SOCIAL SCIENCES

Chair: *P. Higgs, Research Strategy, UCL, London, United Kingdom*
Discussant: *J. Twigg, Kent University, Canterbury, United Kingdom*

Within social gerontology, there is increasing use of the terms the third and the fourth age. These refer to distinct aspects of growing older, one focusing upon agency the other upon dependency. This symposium addresses one aspect of a more general fragmentation of old age in late modern society, that embodied by the term ‘the fourth age’. The ageing body forms a central motif in social science discussions of old age and this theme will be addressed by each of the papers. The first paper situates this theme in relation to the linked concepts of frailty and abjection. This will bring together the biomedical formulation of frailty alongside the subjective framework provided by the idea of abjection as key elements in shaping the fourth age. The second paper focuses on the shifting meanings attached to the normal, the normative and the natural in the social construction of old age. Changes in society as well as changes in ageing, the paper will argue, have challenged the unitary nature of agedness. The final paper examines the specific example of falls and falling as sources of contested narratives over age and identity. In particular the author will discuss the role of bodily transitions in configuring the inside and outside of ageing. Our discussant will synthesise these contributions bringing a critical perspective to the issues of embodiment and the fourth age.

### THE NATURAL AND THE NORMAL: CONFLICTING DISCOURSES OF AGEING

I. Jones[1], P. Higgs[2], *1. Bangor University, Bangor, Gwynedd, United Kingdom, 2. Research Strategy, UCL, London, United Kingdom*

The potential to overcome or significantly reduce the age-associated effects of bodies growing older has led many social gerontologists to argue for a return to a more 'normatively' based conception of ageing and old age. Drawing on the theoretical work of Ulrich Beck and Zygmunt Bauman this paper argues that the normalization of diversity leads to a reworking of the idea of normativity which in turn is reflected in profound transformations at the level of institutional arrangements and legal systems. Such changes not only lead to more discussion of what is legally and socially acceptable but also potentially lead to greater calls for regulation concerning outcomes. In this paper we argue that we need to distinguish between the newly reconfigured domains of the natural, the normal and the normative now being utilised in the understanding of ageing if we are to understand this important field of health.

### FRAILTY AND ABJECTION IN DEFINING THE SOCIAL IMAGINARY OF THE FOURTH AGE

C.J. Gilleard, P. Higgs, *Research Strategy, UCL, London, United Kingdom*

Within social gerontology, there is increasing use of the terms the third and the fourth age. These refer to distinct aspects of growing older, the former focusing upon social agency the latter upon personal dependency. The ageing body forms a central motif in social science discussions of old age, particularly in relation to the fourth age. This paper situates this theme in relation to the linked concepts of frailty and abjection. The biomedical formulation of frailty treats the aged body as a risky entity defined by its vulnerability and potential collapse, while abjection reflects oppression and extreme subjectivity. Both share a concern with risky boundaries viewed however from two distinct interpretive frameworks. We suggest that both concepts should be brought together in order to provide a more incisive understanding of the fourth age as a social imaginary.

### HOLD ON!: FALLING, EMBODIMENT AND THE MATERIALITY OF OLD AGE

S. Katz, *Sociology, Trent University, Toronto, Ontario, Canada*

The theoretical neglect of aging bodies in social gerontology has been challenged by writers who emphasize the materiality of embodiment in everyday practices. This paper applies this emphasis to the example of falls and falling, and how falls embody old age physically and biographically. Bodies fall. But falls by older bodies are experienced, narrated, and treated in ways that can dramatically change health status from independent to dependent, cause a transition in place from home to care institution, shift a resilient identity to a vulnerable one, and configure a new frontier between the inside and outside of aging. Conclusions consider the theoretical importance of falls to research on the body and aging.

## SESSION 245 (POSTER)

## HOUSING, NURSING HOME, RESIDENTIAL AND COMMUNITY CARE

### A STUDY OF ALCOHOL USE AMONG LOW-INCOME ELDERLY RESIDENTS AT SUPPORTIVE HOUSING

J. Min[1], J. Clapp[1], S. Woodruff[1], B. Martell[1], M. Piwowarski[2], M.U. Mazyck[2], E. Ko[1], *1. School of Social Work, San Diego State University, San Diego, California, 2. Senior Community Center of San Diego, San Diego, California*

Alcohol use and abuse among older individuals remains a neglected research and clinical topic. With the rapid growing older population, increasing attention has focused on their alcohol use. The consequences of alcohol abuse for the elderly can be severe and even fatal, especially among elders with low socioeconomic status. A cross-sectional survey was conducted with 174 residents at two supportive housing facilities (i.e., Single Room Occupancy (SROs)) in San Diego metropolitan areas. A face-to-face interview survey was conducted at the facilities. Alcohol use by the residents were assessed by standardized assessment tools such AUDIT, DAST, and Geriatric Version of Michigan Alcoholism Screening Test (MAST). Results indicated that half of the residents were living under poverty, and about 86% of them reported to live alone. Forty-one percent of the residents were identified as drinking alcohol and 10% of them were in hazardous and harmful/high risk for alcohol use based on AUDIT scale. Based on the Surgeon General Guidelines, 16.7% of those who report drinking alcohol showed alcohol use risk problems. Study findings are discussed to highlight the need and strategies for alcohol use or prevention intervention better targeted and tailored not only for older adults, but for those with low SES.

### IS SUPERVISORY SUPPORT ASSOCIATED WITH JOB SATISFACTION AMONG NURSING ASSISTANTS? A MULTILEVEL ANALYSIS

J. Choi, M. Johantgen, *University of Maryland School of Nursing, Baltimore, Maryland*

Purpose: The relationship between Certified Nursing Assistants (CNAs) and their supervisors are assumed to be associated with CNAs' job satisfaction in nursing homes. The study examined the impact of supportive supervision on job satisfaction among CNAs working in nursing homes while accounting for the nested nature of data. Methods: Two-level hierarchical linear models were examined using 2004 data from the National Nursing Home Survey and the National Nursing Assistant Survey (U.S. NCHS, 2007). The sample included 2,897 CNAs who were still employed in the sampled facilities (n = 582) at the time of the 2004 NNAS. Results: Job satisfaction among nursing assistants significantly varied across nursing homes (ICC=.062). Controlling for individual and nursing home characteristics, supportive supervision, organizational value, and benefits were positively associated with CNAs' job satisfaction. Furthermore, the interaction of organizational value by supportive supervision was significantly related to CNAs' job satisfaction; for CNAs with more supportive supervision, the positive relationship between organizational value and job satisfaction was increased. Conclusions: While the supervisory support is often cited as important to worker satisfaction, the findings that more supportive supervision and organizational value contribute to higher job satisfaction among CNAs provide needed evidence. Organizational attributes such as management, supervision, and leadership in nursing homes are not understood well since there are few studies that have explored them. Further research is necessary to develop or test strategies to improve the quality of supervision.

### ASSESSING NURSING HOME CULTURE CHANGE PRACTICES USING THE CMS ARTIFACTS OF CULTURE CHANGE TOOL

A. Kelly, *Florida Southern College, Maitland, Florida*

Using the CMS Artifacts of Culture Change (ACC) Tool, a Florida Pioneer Network (FPN) Project explored culture change practices in 40 Florida nursing homes that were self-described as "on the culture change journey". Inclusion criteria were the administrator/owner's willingness to participate and the presence of a Culture Change Leadership Team (CCLT) that was comprised of all departments, all levels of staff as well as residents. All homes had some familiarity with culture change. The ACC, a 79-item instrument covering six domains, created and made widely available by CMS in 2008, was used with some adaptations with permission for this project. The 18-month project included initial visits, in-depth CCLT work with the ACC instrument, and discussion of barriers and challenges to the adoption of these practices. Themes were developed from the first round of visits and a Forum was held "Advancing Culture Change in Florida", attended by teams from all from participant homes. Expert presentations, including the authors of the ACC instrument, and Spotlight presentations to highlight Florida success stories, were featured. Return visits to each home by the same FPN culture change coaches elicited another round of ACC instrument measures. Five ACC domains were analyzed for this project. There was a significant increase (p=<0.05) in four domains and a positive trend in the fifth domain over the intervention time frame. Analysis of this assessment of nursing home culture change resulted in organizational and state policy recommendations that were widely disseminated. This project was funded by the Retirement Research Foundation.

### TRANSITIONING NURSING HOME RESIDENTS BACK TO THE COMMUNITY: A PERSON-CENTERED APPROACH

R. Meador, K. Pillemer, E. Kahoe*, Cornell University, Ithaca, New York*

The poster will report on qualitative research conducted to evaluate an intervention focused on transitioning current nursing home residents back to the community. It will provide information from a rigorous evaluation of data from the case notes from 60 participants of the program, which provided a rich source of qualitative data about the barriers and attributes associated with going home or staying in the nursing home. Results of the quantitative evaluation revealed that the strategies that addressed these barriers. These strategies included knowledge of local resources, role as client advocate, and ability to work with a client over many months. Overall, results indicate that a flexible, goal-orientated, person-centered approach was central to the success of the program because it transcended many assumptions about client needs, and, in doing so, provided valuable and unique assistance in the transition process.

### HOMELIKENESS IN NURSING HOMES: PERSPECTIVES OF FAMILY CAREGIVERS AND STAFF

L. Strain, D. Wanless*, Sociology, University of Alberta, Edmonton, Alberta, Canada*

Increasing emphasis is being placed on the importance of creating homelike environments in nursing home settings. This study focuses on homelikeness from the perspectives of family caregivers and staff in a rural Canadian nursing home that experienced a transition from an old institutional-style facility to a new cottage-style, purpose-built facility. Prior to the move, 37 family caregivers and 56 staff members were interviewed in person and asked to rate the homelikeness of the facility, provide an explanation of their rating, and discuss elements that were homelike or not homelike to them. These questions were repeated four months and 12 months after the move. In addition, the Therapeutic Environment Screening Scale for Nursing Homes (TESS-NH) (Sloane et al. 2002) was completed in both settings. The new facility was rated as more homelike than the old facility by 67% of family caregivers and 83% of staff. Both the physical and social/care environments were taken into account in their assessments. Private rooms, personal decorations and the smell of the food were common elements of homelikeness. Rules/routines, time schedules, and institutional beds made the facility less homelike. Staff members were identified by some family caregivers as contributing to homelikeness. Scores on the homelikeness sub-scale of the TESS-NH showed marked improvements. The multidimensionality of the concept of homelikeness is discussed as are implications for future research and for the design of homelike living environments for frail older adults in residential care settings.

### PLACE-MAKING INTERVENTIONS AND AGING-IN-PLACE IN SMALL DYING TOWNS: A REPORT FROM THE GREAT PLAINS

R.J. Scheidt*, School of Family Studies and Human Services, Kansas State University, Manhattan, Kansas*

Chronic and acute economic forces threaten the physical, social, and cultural viability of many small towns in the U.S Heartland. Depopulation and loss of their economic, service, and physical infrastructures deeply affect over half of the small towns (2,500 and under)in Kansas (Kulczar, 2009). Older residents who seek to successfully age-in-place in these severely declining environments increasingly adopt the emerging role of indigenous "place-maker" (Rowles, 2010 )to sustain these towns. This involves actively preserving as well as shedding existing place meanings and place attachments as environments change. This session uses selective photographic and narrative responses from three dozen long-time older residents (65 + years) across 4 prototypical Kansas towns (Pop. 100 to 250) to illustrate the processes and products of the making and re-making of place. Goldsmith's (2008) Complex Adaptive System is used to order the elements(people, spaces), interactions (experiences), and outcomes (emergent places at individual and community levels) of local place-making. Five primary interventions are visually illustrated: reculturation, e.g., the introduction of new rituals to reverse perceived deculturation created by "junk people" (new, younger, and poorer in-migrants); intentional place deconstruction and memorialization ("place grieving"); re-assignment of place meanings and place attachments to remaining places following setting loss ("place compensation"); the reinvention of community identity to replace stigmatizing town images ("place covenant"); and strategies for budgeting limited social capital among dwindling pools of older volunteers . The relevance of place-making for "place therapies" (Scheidt & Schwarz, 2010)involving elders at the individual and community levels is highlighted.

### DO HOME AND COMMUNITY-BASED SERVICES PROGRAMS PROVIDE COST SAVINGS TO STATES ? A PROSPECTIVE EXAMINATION OF FLORIDA NURSING HOME RESIDENTS' DIVERGENT PATHS

A. Shapiro, C. Loh*, Sociology & Anthropology, University of North Florida, Jacksonville, Florida*

Despite the fact that there is evidence of the efficacy of home and community-based services (HCBS) to improve quality of life, reduce institutionalization, and decrease mortality, the cost-effectiveness of these HCBS programs is still unclear. Using data from the Minimum Data Set (MDS) and the State of Florida's Client Information and Registration Tracking System (CIRTS) this study is designed to provide estimates of Medicaid and General Revenue cost-savings resulting from the use of HCBS. We employ a quasi-experimental design using a three-group approach (those who utilized HCBS, those who applied for services but did not receive, and those who neither received nor applied) to track individuals prior to and after nursing home entry. Our findings suggest that HCBS enrollees have aggregate cost savings relative to non-enrollees. These findings buttress those from earlier studies in Florida make a strong case for the cost efficacy of HCBS programs.

### MEASURING OUTCOMES FOR RESIDENTS OF CARE HOMES

A. Netten[1], B. Trukeschitz[2], J. Beadle-Brown[1], A. Towers[1], E. Welch[1], J. Forder[1]*, 1. University of Kent, Canterbury, United Kingdom, 2. University of Vienna, Vienna, Austria*

An innovative approach to measuring outcomes, which identifies current and expected social care related quality of life (SCRQOL) in the absence of services and relates these to low burden or routinely available data, has been developed for care homes as part of the Adult Social Care Outcomes Toolkit (ASCOT). A study of 741 residents in 173 care homes for older people and people with learning disabilities in England collected in depth information about their experiences and current and expected SCRQOL. The fieldwork, which was multi method including structured observation, was conducted close to the inspections of the homes and data collected about quality ratings. Inter-rater reliability was tested and multilevel modelling used to relate individual and home characteristics, including quality ratings, to outcomes. Inter-rater reliability was reasonable with percentage agreement close to 0.8 and detailed information collected that could be used to improve this in future. Expected SCRQOL was more reliably measured than current SCRQOL and was highly associated with individual measures of activities of daily living, communication problems and mental state. While a high level of outcome was identified in basic areas of SCRQOL such as personal cleanliness, food and safety, they were more limited in 'higher order' domains such as social participation, occupation and control. Outcomes were associated with care home quality ratings, but to a limited degree and the same relationship was not found for nursing homes for older adults, which were associated with poorer SCRQOL outcomes. The results of the study are feeding into the new English regulatory regime.

### THE NEIGHBORHOODS FOR ALL AGES: AN INITIATIVE FOR SENIOR SUPPORTIVE NEIGHBORHOODS

A. Cohen-Callow[1], B.L. Casado[1], R. Edds[2], J. Macgill[3], A. Jones[1], *1. School of Social Work, University of Maryland Baltimore, Baltimore, Maryland, 2. Edds Consulting, LLC, Baltimore, Maryland, 3. Association of Baltimore Area Grantsmakers, Baltimore, Maryland*

Many low-income older adults face potential loss of their homes, their most important asset, because of financial burdens related to repairs of declining housing stock. This is exacerbated by the high cost of food, utility and health care bills, challenging their ability to remain comfortably and independently in their homes. The Neighborhoods for All Ages Initiative is a pilot program implemented by two grantees each doing so in a uniquely different manner. Both targeted issues faced by low-income older adult city dwellers by helping them to make their homes safer and energy efficient, to gain access to services and benefits, and to strengthen the connections to neighbors. This study examined whether this program contributed to desired outcomes for older adult participants (N = 151) of the program. The AdvantAge Initiative Model provides a framework for the study and stipulates four elements of an age friendly environment: meeting basic needs, optimizing physical and mental health, maximizing independence, and addressing social and civic engagement. Urban participants were a mostly female (75.2%), African Americans (92.6%), and low income (56.2% less than $1,500/month). Dependent t-tests for both grantees' clients indicated decreased unmet needs for services, improved self-report of health and quality of life, improved perceptions of their home environment, and a significant decrease in social isolation (measured by the proxy of civic engagement). The theoretical framework, program implementation along with the outcome measurement process utilized in this study provides knowledge to program developers and policymakers to promote aging in place initiatives in urban settings.

### UNMET NEEDS FOR HOME AND COMMUNITY-BASED SERVICES AMONG FRAIL OLDER AMERICANS AND THEIR CAREGIVERS

K.S. van Vulpen[2,1], B.L. Casado[2], *1. Social Work, Salisbury University, Salisbury, Maryland, 2. University of Maryland, Baltimore, Baltimore, Maryland*

Home and Community-Based Services (HCBS) emphasize the role of informal caregivers and are designed to alleviate burden so that they can assist their disabled older adults to remain living in their homes and communities. The purpose of this study is to explore reasons why family caregivers of older Americans do not utilize HCBS services and to identify predictors of unmet needs for seven types of HCBS; including temporary and respite care, community-based programs; personal and nursing care at home, caregiver support groups, housework services, home delivered meals, and transportation services. A sample of 1,021 direct family caregivers was drawn from the 1999 National Long Term Care Survey. Results of the study indicated that although about one-third of the family caregivers utilized personal/nursing care services, the other types of HCBS went largely underutilized (utilization for other HCBS ranged from 4.2% to 16.6%). Caregivers reported lack of awareness and reluctance to have an outsider coming in their home as the main reasons for not using the services. A hierarchical logistic regression identified similarities in predictors of unmet needs across most types of HCBS: black ethnicity, greater ADL/IADL limitations, more severe care recipient behavior problems, lack of substitute caregiving support, and less family agreement. Findings from this study provide knowledge to policy makers and service providers to better understand the reasons for unmet HCBS needs, identify the risk factors for unmet HCBS needs, and consider strategies to address such risk factors.

### CREATING A COMMUNITY OF GENERATIONS IN RURAL AREAS AND INDIAN RESERVATIONS

C. Mehrotra[1], Z.L. Bail[2], L.M. Haglin[2], *1. The College of St. Scholastica, Duluth, Minnesota, 2. Northland Foundation, Duluth, Minnesota*

Following a region-wide study to examine civic engagement among people 55 and older in northern Minnesota rural communities and Indian Reservations, the Northland Foundation launched AGE to age: Bringing Generations Together. Research revealed that older adults were highly concerned regarding the well-being of young people. Clearly, there was a need to create a community of generations where older adults and youth pool their unique strengths to ensure community vitality. The Foundation worked with 10 communities to develop locally-driven civic engagement projects that meet their unique needs. These sites range in population from 400 to 11,000 with high poverty rates. Foundation staff guided older people, youth, and other adults through a planning process to identify needs and opportunities, engage in community dialogue, craft a local vision, and develop an action plan. Activities initiated to date include: learning to use information technology, sharing cultural traditions, promoting health and wellness, implementing environmental projects, and participating in social and recreational activities. A regional learning community has been created to promote networking relationships, offer continuing education, and share lessons learned. Formative evaluation indicates: (a) Improved health and well-being of older adults and young people; (b) Increase in their leadership capacity; (c) Development of new relationships between older adults and youth; (d) Improved understanding of American Indian culture and traditions; and (e) Reduced isolation and age-segregation. Given the outcomes already achieved to date, a number of funding agencies are now providing support to help sustain the momentum of the program has generated in rural communities. [Support for this program is provided through the Community Experience Partnership, an initiative for U.S. community foundations from The Atlantic Philanthropies, along with additional funding from the Blandin Foundation, Bush Foundation, Communities for All Ages, an initiative of Temple University funded by the W.K. Kellogg Foundation.]

### TRANSLATING RESEARCH INTO PRACTICE IN NURSING HOMES

A. Rahman, *Scripps Gerontology Center, Miami University, Cincinnati, Ohio*

A gap between research and practice in many nursing home care areas persists despite efforts by researchers, policymakers, and consumers to close it. The reasons are many, including lack of knowledge among staff, staffing challenges, and inconsistent regulatory practices. Two barriers that have received scant attention are the development of evidence-based improvement interventions and the translation process itself. This poster examines these two elements through the lens of innovation dissemination. Decades of research across disciplines has led to the identification of a body of generalizations that, for the most part, have held true across studies. This poster applies these dissemination principles to known characteristics of the nursing home system to make initial assumptions about nursing homes' ability to use new information or adopt new interventions. Findings suggest, for example, that nursing homes are characteristically slow to innovate. This and other underlying assumptions should then drive the development of translation strategies. The poster then critiques various translation strategies reported in the nursing home literature to identify what works. Findings indicate, for example, that some recommended care interventions may be more effective than they are feasible for nursing homes to implement and that information dissemination, perhaps the most commonly used innovation adoption strategy, is less effective than ongoing interaction between change advocates on the one hand and nursing home providers on the other. Drawing from lessons learned in multiple disciplines, including acute and public health care, the poster reviews promising translation strategies for speeding the adoption of evidence-based practice in nursing homes.

## SESSION 250 (SYMPOSIUM)

### KNOWLEDGE TRANSLATION TO SUPPORT OLDER DRIVERS: A MULTI-FACETED PROCESS

Chair: *M. Bedard, Public Health Program, Lakehead University, Thunder Bay, Ontario, Canada*
Co-Chair: *M. Berg-Weger, St. Louis University, St. Louis, Missouri*
Discussant: *D.W. Eby, University of Michigan, Ann Arbor, Michigan*

The creation of new knowledge is an important part of the research process. However, the dissemination of this knowledge and eventual translation into practice are equally important. The translational aspect of research relevant to older drivers is particularly difficult, whether it relates to the creation of guidelines for assessment, policy changes, or the development of products to support safe driving. It also has potentially important consequences for society and the quality of life of older drivers. Ultimately, society, and especially older drivers, should be better off following knowledge translation than they were before. To ensure this goal, the readiness of the new knowledge for translation must be confirmed, and the necessary steps to translate knowledge need to be clearly delineated, communicated, and applied vigilantly. Failing to do so may result in little, if any, advancement, ultimately questioning the ethical value of the knowledge translation. Hence, adhering to accepted principles and best practices for knowledge translation, and implementing safeguards to ensure the process results in the desired changes, are essential. The goal of this symposium is to introduce these issues. Specifically, we will discuss how universities emphasize and support knowledge translation, the different steps in the knowledge translation process, and the guidelines and safeguards that should be in place to ensure the end results of knowledge translation truly make a difference for society and older drivers.

### THE SAFE DRIVING BEHAVIORS MEASURE: READINESS OF THE NEW KNOWLEDGE FOR TRANSLATION

S. Classen, *University of Florida, Gainesville, Florida*

This presentation will address the readiness of the new knowledge for translation. We will provide a systematic overview of the research process to develop, test, and improve upon a 68-item self/ proxy report Safe Driving Behaviors Measure. This measure was developed to be applied, eventually, to the broader population of older drivers and caregivers in North America. We used a multi-method approach for assessing the readiness of knowledge for translation. These included safe driving frameworks, limitations of existing self-reports, modern test theories, principles of community based participatory research, and a reliability and validity typology. We will share the feedback from community partners, expert raters and peer reviewers, and converge the evidence from six empirical studies to focus on the next step: translation of knowledge.

### TAKING IT TO THE STREETS: LESSONS LEARNED FROM THE REACH OUT TRANSLATION TRIALS

L. Burgio, *University of Michigan, Ann Arbor, Michigan*

REACH OUT is an evidence-based translation of the REACH RCT developed through clinical trials to support dementia caregivers living at home. More specifically, REACH OUT was adapted for implementation by case managers in Area Agencies on Aging (AAAs). Many lessons have been learned during our efforts to transfer REACH knowledge and skills to the community. Implementation in multiple AAAs required the coordination of activities among administrators and clinical staff across these Agencies. Program planners and coordinators must contend with real world challenges such as budget constraints, limited human resources, and competing missions. Through the use of Community-based Participatory methods, the program was well-received by dementia family caregivers, and by the staff implementing the program. Examples will be presented of various barriers confronted during the trials, and procedures used to overcome these barriers.

### TRANSLATIONAL RESEARCH ON AGING AND MOBILITY

K. Ball, L.A. Ross, *Department of Psychology, University of Alabama at Birmingham, Birmingham, Alabama*

Translational research has become an increased focus for many funding agencies in recent years. This term means more than “bench to bedside,” and now encompasses the movement of basic theoretical research conducted in a university laboratory to community settings, and ultimately to changes in policy and government practices. This session will provide a discussion of how to achieve translation in the area of transportation and older drivers, using examples from the UAB Roybal Center for Translational Research on Aging and Mobility. Transitions from laboratory-based studies, to clinical trials, to efficacy studies in field sites and collaborations with state agencies and private industry will be outlined. The methods employed to evaluate translational research targeted to improve the safety and mobility of the older driver will be discussed.

### BEST PRACTICES AND ETHICAL ISSUES IN KNOWLEDGE TRANSLATION

M. Bedard, *Public Health Program, Lakehead University, Thunder Bay, Ontario, Canada*

There is an ever-increasing focus placed by academic institutions on the translation and commercialization of research knowledge produced by academics. The Canadian Institutes of Health Research define knowledge translation as “…a dynamic and iterative process that includes synthesis, dissemination, exchange and ethically-sound application of knowledge to improve the health of Canadians, provide more effective health services and products and strengthen the health care system.” A key ethical aspect of this statement is that the health of seniors should be improved after knowledge translation. In this presentation the author will discuss best practices and safeguards to ensure that knowledge translation achieves its objectives. Specifically, that it leads to better outcomes for seniors.

## SESSION 255 (SYMPOSIUM)

### MAKING MEANING THROUGH THE TRANSITIONS OF CARE AT LIFE’S END

Chair: *D. Waldrop, School of Social Work, University at Buffalo, Buffalo, New York*

People who are in the advanced stages of chronic illness and their families move through key transitions in care as death approaches. Significant physical and functional changes accompany the dying process, often with manifestations of psychosocial, spiritual and existential distress. Existential distress is exacerbated by feelings of hopelessness, futility, disappointment, and remorse, as well as ongoing changes in social roles and relationships, which can contribute to a sense of meaninglessness. This symposium will address the critical importance of making meaning out of all that is occurring to address existential distress in end-of-life transitions. The first paper identifies aspects of distress in older African Americans who are living with heart failure and illustrates how elders make sense of their illness and demonstrate resilience through their spirituality. The second paper presents the process of integrating the perspectives of terminally ill elders and healthcare professionals in the development of an instrument for assessing the psychosocial and spiritual distress and needs of elders who are dying. The third paper conceptualizes the point of reference as key to understanding decision-making in transitions of care in nursing homes and applies the concepts of Prospect Theory to illuminate the resolution of distress as comfort with dying. The fourth paper explores relational dynamics in caregiver dyads, who renegotiate subjective and intersubjective meanings throughout the course of progressive chronic illness. The fifth paper presents interventions (e.g. the use of the environment and rituals) as ways of creating meaning for families of people who die in hospice house care.

### MEANINGFUL PLACES: USING ENVIRONMENT AND RITUAL IN HOSPICE HOUSE CARE

D. Waldrop, *School of Social Work, University at Buffalo, Buffalo, New York*

Most people express the wish to die at home but not all deaths can be managed this way. Hospice houses have emerged as an alternative, “home-like” environment for care when a dying person can no longer remain at home. The purpose of this study was to identify the similarities and differences in hospice house care in different communities. Ethnography or systematic observation was conducted in 8 hospice houses followed by in-depth interviews (N=225) with hospice house staff members and volunteers. The results indicate that hospice houses are uniquely characteristic of the community with distinct environmental features that: (a) reflect the development of the individual house and, (b) illustrate shared meaning about the importance of “environmental serenity” – a peaceful place for dying. In addition, hospice houses develop rituals: (a) interpersonal and (b) nonverbal to ease the dying process for families and staff. Implications for transitions in end-of-life care will be discussed.

### RELATIONAL MEANING-MAKING AMONG CAREGIVER DYADS IN PALLIATIVE AND END-OF-LIFE CARE

D.S. Gardner, *Silver School of Social Work, New York University, New York, New York*

Much of the empirical and clinical literature on living with chronic and terminal illness examines the psychosocial impact of infirmity on the caregiver and the care receiver separately, essentially splitting the dyad in order to understand a shared experience. This paper explores dyadic processes among older care partners, and suggests that a deeper understanding of the caregiving dyad’s subjective and intersubjective perceptions can yield enhanced insight about the needs of older couples living with life-threatening illness. Based on findings from two studies, one of older couples living with advanced cancer and the other of dementia patients and their family caregivers, the paper moves beyond an individualistic caregiving paradigm to develop a conceptual model of shared and co-constructed meaning in palliative and end-of-life care. By analyzing relational narratives of communication, mutuality, conflict, and meaning-making, the studies highlight clinical practice and research that honors the dyadic, familial, and social contexts of care.

### URBAN ELDERS AND THEIR CAREGIVERS: MEANING MAKING IN THE CONTEXT OF ADVANCED HEART FAILURE

F.P. Hopp, N. Thornton, *Social Work, Wayne State University, Detroit, Michigan*

Purpose: To obtain more information on the lived experience of African American elders with heart failure and adult daughter heart failure caregivers. Method: Focus groups and individual patient interviews for African Americans age 60 and over with advanced heart failure (n=35) and seven adult daughter caregivers living in Detroit, Michigan. Qualitative data was analyzed for relevant themes. Results: For caregivers, meaning making include valuing their role as caregivers and taking charge of the caregiving experience. Meaning making for the elders included making sense of their condition, self care, and resilience. Meaning making for both elders and caregivers involved drawing on spiritual strengths. Conclusion: Elders and caregivers engaged in both contrasting and parallel meaning making strategies. These contrasting styles reflect their different roles and experiences. Spirituality emerged as a powerful meaning making strategy for both elders and caregivers, reflecting the salience of spiritual strengths in the African American community.

### ASSESSING TERMINALLY ILL ELDERS’ PSYCHOSOCIAL AND SPIRITUAL NEEDS

T.A. Schroepfer, *School of Social Work, University of Wisconsin-Madison, Madison, Wisconsin*

A fundamental task of end-of-life healthcare professionals is the assessment of terminally ill elders’ psychosocial and spiritual needs; however, quality assessment instruments are necessary to perform this critical task accurately. The purpose of a four-part study is to create an assessment instrument based on information gathered from terminally ill elders and healthcare professionals. In Part One, in-depth face-to-face interviews were conducted with 100 terminally ill elders, and data content analyzed to identify main themes. In Part Two, 100 additional elders were interviewed using a survey that included newly developed measures informed by Part One findings, as well as new open-ended exploratory questions. Part Three, which is in progress, seeks to gather information from professionals in the field who conduct assessments. The results of parts two and three will be discussed, as well as their implications for Part Four: the testing of the newly created assessment instrument.

### PROSPECT THEORY AND END-OF-LIFE DECISION-MAKING IN THE NURSING HOME CONTEXT

M. Bern-Klug, *Social Work, University of Iowa, Iowa City, Iowa*

Using an adaptation of qualitative descriptive methods (Sandelowski, 2000), data from 24 family members of nursing home residents with cancer were analyzed through the lens of Tversky & Kahneman’s (1981) Prospect Theory (PT) (a model for understanding decision-making in the context of risk). Findings suggest that these family members use a “big picture” approach to medical decisions and that the respondents’ reference point is affected by their experience with this resident under the context of earlier cancer diagnoses, and other family members’ cancers, as well as the sense that the resident had already lived longer than expected. Family members were working toward comfort –rather than fighting death. The findings underscore that the reference point of the decision maker is crucial to understanding decision-making, and suggest that family members of NH residents with cancer may differ in their reference point from family members of residents with organ failure and frailty.

## SESSION 260 (PAPER)

## NATIONAL POLICY ISSUES AND AGING I

### HOW PUBLIC-PRIVATE PARTNERSHIPS ARE MAKING AN AGE-FRIENDLY NEW YORK CITY

K.M. Meade, R. Finkelstein, D.E. Block, *New York Academy of Medicine, New York, New York*

Age-friendly New York City, affiliated with the World Health Organization (WHO), is a public-private partnership between The New York Academy of Medicine (NYAM), the New York City Mayor’s Office, and New York City Council. The initiative is led by a public-private Commission, engaging multiple sectors in an ongoing effort to build on the existing strengths of the City to maximize the health and participation of New Yorkers of every age, in every neighborhood and community.

Now in its 3rd year, a newly appointed high-level Commission comprised of business leaders, civic leaders, and elected officials has identified age-friendly models and principles and are beginning to implement them. For example, administrators from private and public universities, community colleges and schools across the city are developing principles and models for age-friendly schools; city agencies and business leaders across sectors are developing principles for age-friendly employers and customer service; and a work-group of health care professionals, aging service providers, leaders of cultural institutions and city council members, are further developing and piloting the concept of "aging improvement districts," neighborhood-level projects to organize community improvements for and by older adults. This symposium will include a dynamic discussion of the concept of an "age-friendly city" and the role of public and private partnerships in obtaining buy-in and ensuring the success of such an initiative. Participants will leave with concrete examples of such partnerships and how they may be replicated.

### THE MEDICARE PART D COVERAGE GAP: MEDICATION ACCESS, ADHERENCE, AND FACTORS IMPACTING COMPLIANCE

L. Bakk[1], A.T. Woodward[1], J. McGuire[2], *1. Social Work, Michigan State University, Novi, Michigan, 2. Area Agency on Aging 1-B, Southfield, Michigan*

Prescription drugs are increasingly important in older adults' treatment regimen. However, cost-sharing requirements associated with the Medicare Part D coverage gap can inhibit medication access and use. While 26 percent of Medicare Part D enrollees experience the coverage gap, only 4 percent of those reaching this benefit threshold incur enough out-of-pocket spending to receive catastrophic coverage. The reasons for this are not completely clear, but likely to include older adults rationing their own medications to lessen financial hardship. This exploratory study examined the effect of the Medicare Part D coverage gap on medication access and adherence. Data were collected from 22 enrollees over the age of 50 in Medicare Part D plans that experienced the coverage gap. Qualitative, semi-structured interviews were utilized to determine problems faced by enrollees and factors impacting compliance. Data were analyzed using NVivo. Results indicate that medication adherence varies and is affected by the coverage gap. The most common themes suggesting reasons for nonadherence are drug cost, number and type of prescribed medications, and the enrollee's gender, income, and health status. Medication samples and prescription assistance programs were frequently utilized to avoid or delay the coverage gap, and were critical factors in maintaining compliance. However, restrictions imposed by these resources can limit the amount and type assistance available, and subsequently impact adherence. Additionally, the complexity of the benefit can act as a barrier to medication access. These results support previous research suggesting that the Medicare Part D coverage gap is problematic for older adults.

### A TASTE OF WHAT'S TO COME: CHANGES IN INDIVIDUAL EXPECTATIONS ON AGEING AND LATER LIFE IN TIMES OF WELFARE STATE REFORMS AND ECONOMIC CRISES

A. Motel-Klingebiel, J. Simonson, *German Centre of Gerontology (DZA), Berlin, Berlin, Germany*

Resources, needs and evaluations are dimensions of quality of life and pre-conditions for autonomy and life planning. Projections of older people's future living standards in Europe predict declining levels and increasing inequality due to pension reforms and changing employment patterns. Effects of ongoing economic crises need also to be considered as well as changing needs, expenditures and values of older people. Recent data from the German Ageing Survey (DEAS) demonstrate stable socio-economic resources and increasing inequalities among retirees. The most important trend is an increase in concerns about future living standards which is very significant from a social policy as well as from a gerontological perspective. Based on this data, the presentation calls for its sources and conclusions to be drawn. It presents descriptive information and results from multi-level modelling. It heightens awareness of changes in later life due to reforms and crises and will contribute to a wider understanding of multi-level interactions between individual resources, evaluations and societal development. The DEAS is a representative cross-sectional and longitudinal survey of those aged over 40 (n=8200 in 2008) in Germany, funded by the Federal Ministry for Family Affairs, Senior Citizens, Women and Youth (BMFSFJ). Three hypotheses – a) hypothesis of social structure effects, b) hypothesis of cohort change of later life, c) hypothesis of differentiation of inequality patterns – are tested and mostly supported by the study. Analyses show that increasing concerns interact with income and portfolio structures but are partly independent of education and gender. Moreover, differences between regions mirror context effects.

### UNMET NEEDS OF CLIENTS WHO TRANSITION TO NURSING HOMES FROM A MEDICAID HCBS ELDER WAIVER

J. Robison[1], L. Curry[2], R. Fortinsky[1], M. Porter[1], N. Shugrue[1], D. Lambert[3], *1. University of Connecticut Health Center, Farmington, Connecticut, 2. Yale School of Medicine, New Haven, Connecticut, 3. CT Department of Social Services, Hartford, Connecticut*

Long term care services use and costs will skyrocket as the baby boomers age, demanding creative solutions to address long term support needs. Most states have implemented Medicaid Home and Community-Based Services (HCBS) waivers to allow people with long term support needs to remain in the community rather than move to a nursing home. Connecticut's HCBS waiver for older adults, the CT Home Care Program for Elders (CHCPE), serves over 15,000 clients. However, over 50% of CHCPE clients who leave the program enter a nursing home. We sought to identify unmet needs and service gaps in the CHCPE for this group of individuals. Methods: This mixed methods study, part of the Money Follows the Person Rebalancing Demonstration, had three components: a) systematic review of CHCPE administrative data for all clients discharged to a nursing home in 2008 (n=1468), b) in depth review of a 15% random subsample of care manager case notes (n=224), and c) focus groups with care managers to identify program gaps leading to nursing home admission (n=3 groups, 24 participants). Results: Focus group and case notes identified similar gaps in the CHCPE: e.g., lack of informal and formal support on nights and weekends, inadequate means of managing mental health and substance abuse issues, and lack of an intermediate level of provider such as personal care assistance. Hospitalizations, rehabilitative nursing home stays, falls, and worsening chronic conditions were common triggers. Conclusions: Findings can guide efforts to restructure financing and delivery of Medicaid HCBS programs aiming to prevent institutionalization.

## SESSION 265 (SYMPOSIUM)

### NIA SYMPOSIUM: CARE TRANSITIONS-BENCH TO BEDSIDE-ADVANCES & TRAINING OPPORTUNITIES IN AGING RESEARCH

Chair: *R.J. Hodes, National Institute on Aging, Bethesda, Maryland*
Co-Chair: *M. Bernard, National Institute on Aging, Bethesda, Maryland*

Organizers: R.J. Hodes, Director, and MA Bernard, Deputy Director, National Institute on Aging, NIH, Bethesda, MD. Participants: RJ Hodes, Director, NIA; RA Barr, Director, Extramural Activities. Additional Roundtable Participants include MA Bernard, Deputy Director; F Sierra, Aging Biology; E Hadley, Geriatrics and Clinical Gerontology; R Suzman, Behavioral and Social Sciences; M Morrison-Bogorad, Neuroscience; JT Harden, Office of Special Populations, and C Hunter, Training Office. The symposium includes two podium presentations and roundtable discussions. Participants in this interactive symposium will provide an overview of recent research advances, across the continuum of care, from bench to bedside, addressing aging research as an answer to challenging questions about aging biology, Alzheimer's disease, geriatric conditions, and health and retirement issues of older adults. The National Institute on Aging conducts and supports biomedical and behavioral research with a focus on understanding basic processes of aging, improving prevention and treatment of diseases and conditions common in later years, and improving the health of older persons. An overview of NIA appropriations and recent advances in aging research will be highlighted in the first podium presentation. The NIA also supports training and career development of scientists focusing on aging research and the development of research resources. This topic will be the focus of the second podium presentation, followed by interactive roundtable discussions.

### NIA SYMPOSIUM: INTERACTIVE ROUNDTABLE DISCUSSIONS ON RESEARCH AND CARE ACROSS THE AGE CONTINUUM

J. Harden*, National Institute on Aging, Bethesda, Maryland*

Organizer: J Taylor Harden, Assistant to the Director for Special Populations, National Institute on Aging, NIH, Bethesda, MD. Participants include: RJ Hodes and MA Bernard, Office of the Director/Deputy Director; F. Sierra, Aging Biolog; E Hadley, Geriatrics and Clinical Gerontology; R Suzman, Behavioral and Social Sciences; M Morrison-Bogorad, Neuroscience; JT Harden, Office of Special Populations; and C Hunter, Training Office. This interactive symposium affords participants the opportunity to meet with the leadership and staff of NIA extramural research divisions and offices. The roundtable discussions may focus on latest advances in research at the NIA, career development plans and concerns, questions about review, and pre/post award management. Participants may prepare a one-page abstract to discuss and leave with staff for follow-up or use the time for mini-mentoring sessions as many of the leaders in extramural research communities attend this symposium. The NIA conducts and supports biomedical and behavioral research with a focus on understanding basic processes of aging, improving prevention and treatment of diseases and conditions common in later years, and improving the health of older persons. Come join the fun and talk about why aging research, and why you care.

### NIA SYMPOSIUM: TRAINING OPPORTUNITIES IN AGING RESEARCH - A RUN THROUGH THE NIA AND NIH MAZE

R. Barr*, National Institute on Aging, Bethesda, Maryland*

Organizers: RJ Hodes and RA Barr, National Institute on Aging, NIH, Bethesda, MD. Participant: RA Barr, Director, NIA Division of Extramural Activities. The presentation will focus both on updates on the changing structure of the NIH peer review and application process and on grant opportunities available for research and research training at NIA. It will also offer some tips on navigating the current funding climate for research support at NIA and elsewhere at NIH.

## SESSION 270 (SYMPOSIUM)

### ENDOCRINE FUNCTIONS IN LIFESPAN AND DISEASE

Chair: *G.J. Lithgow, Buck Institute for Age Research, Novato, California*

Many of the major modulators of lifespan in simple animals are involved in the production or sensing of endocrine signals. Such signals often modulate metabolism in response to altered nutrition state. Consequently, such endocrine signals are associated with major human chronic disease such as Type II diabetes and metabolic syndrome. Other signals regulate bone remodeling with profound healthcare implications. Can we begin to optimize endocrine signaling to maximize successful aging? We will explore a number of endocrine systems and their significance at the aging/disease interface. Speakers: Ronald C. Kahn, M.D., The Joslin Diabetes Center, Harvard Medical School. Vijay Yadav, Ph.D., Columbia University William Sonntag, Ph.D., Reynolds Oklahoma Center on Aging

## SESSION 275 (SYMPOSIUM)

### AGE DIFFERENCES IN DECISION MAKING: THE ROLE OF MOTIVATION AND EMOTION

Chair: *C.E. Loeckenhoff, Cornell University, Ithaca, New York*

Discussant: *J. Strough, West Virginia University, Morgantown, West Virginia*

A growing body of research documents systematic age differences in various aspects of choice and decision-making. Research further suggests, that such effects are not fully explained by cognitive decline. Age-related variations in motivational states and emotional responses appear to play an important role as well. The individual presentations in this symposium illustrate such effects in the context of choice preferences, intertemporal choice, and health-related decisions. First, Reed, Mikels, and Loeckenhoff present a series of studies demonstrating that advanced age is associated with a preference for smaller choice sets and that motivational priorities contribute to this phenomenon. The following two presentations convey converging evidence for a role of affect in age differences in intertemporal choice: Loeckenhoff, O'Donoghue, and Dunning examine age differences in temporal discounting for gains and losses in a life-span sample. With advanced age, individuals make more patient choices and their anticipated emotions are less sensitive to delay. Consistent with these findings, Samanez-Larkin, Carstensen, and McClure report that older adults are less likely to discount delayed rewards than younger adults. Moreover, neuroimaging analyses suggest that the mesolimbic reward system is less sensitive to delay among older versus younger adults. Next, Nothoff and Carstensen discuss the use of message framing to encourage physical activity among older adults. Their findings suggest that gain-framed messages are more effective than loss-framed messages – particularly among older adults who are high in self-efficacy. Finally, Strough will integrate these findings with the aging and decision making literature and discuss directions for future research.

### CHOICE ACROSS THE ADULT LIFE SPAN: WHO WANTS IT, HOW MUCH, AND WHY?

A.E. Reed, J. Mikels, C.E. Loeckenhoff*, Cornell University, Ithaca, New York*

The proliferation of choice in modern society is ubiquitous, but is it equally welcomed by adults of different ages? The present studies examined age differences in preferences for, valuation of, and interest in varying degrees of choice in decision-making, as well as underlying influences on these age differences. Participants (N = 457, age range = 18-94) completed novel measures of choice preferences and valuation, self-efficacy, and motivational priorities, as well as validated measures of decision strategies, personality factors, and cognitive abilities. Results indicate that the desire for choice wanes with age across a variety of decision domains, with larger choice sets especially aversive to older versus young adults. Additional results suggest that age differences in choice preferences reflect a constellation of changes in motivational and cognitive processes across the adult life span. Implications for theories of aging and decision-making, as well as public policy, are discussed.

### AGE DIFFERENCES IN TEMPORAL DISCOUNTING OF REALISTIC MONETARY GAINS AND LOSSES

C.E. Loeckenhoff, E. O'Donoghue, D. Dunning*, Cornell University, Ithaca, New York*

We examined age differences in temporal discounting, the tendency to devalue delayed outcomes relative to immediate ones, with particular emphasis on the role of affective responses. Participants (N=98, aged

19-91, M=50, SD=20, 58% female) completed an incentive-compatible temporal discounting task involving both gains and losses. They also rated affect at baseline, anticipated affect in response to immediate and delayed gains and losses, and affective responses to the choice scenarios. Age was negatively associated with the tendency to discount the future, although this effect only reached statistical significance in conditions involving delayed gains ($p < .05$), but not in conditions involving delayed losses ($p > .2$). Age was not associated with baseline or choice-related emotions. However, whereas younger adults anticipated that they would feel less positive about future gains and less negative about future losses, older adults' anticipated emotions did not differ across delay intervals ($p < .001$).

### NEURAL MECHANISMS UNDERLYING INTERTEMPORAL CHOICE IN YOUNGER AND OLDER ADULTS

G.R. Samanez-Larkin, L. Carstensen, S.M. McClure, *Psychology, Stanford University, Stanford, California*

Many of the decisions that affect quality of life as we age involve a trade-off between instantaneous gratification and long-term good (intertemporal choices). This study investigated the neural mechanisms supporting intertemporal decisions in younger and older adults. We hypothesized that for relatively infrequent events, such as those in which an action leads to a reward after a long delay, significant experience may be necessary to learn how to appropriately value delayed rewards. Thus age-related experience may contribute to the tuning of neural reward systems which may result in behavioral increases in patience. Consistent with this hypothesis, we found that older adults were more willing to wait for delayed monetary rewards. Neuroimaging analyses revealed that intertemporal decisions activate mesolimbic regions in both age groups. However, whereas younger adults show greater activity for immediate than delayed choices, older adults show similar activation in these reward-related regions for both immediate and delayed choices.

### DECIDING TO EXERCISE: THE ROLE OF MESSAGE FRAMING AND SELF-EFFICACY

N. Notthoff, L. Carstensen, *Department of Psychology, Stanford University, Stanford, California*

Very few older people decide to be physically active, despite widely advertised scientifically documented positive effects on aging outcomes, possibly because information is not communicated to them effectively. In two studies (n1=57; n2=59), we examined whether emphasizing potential gains may lead to increased choice of physical activity among older adults since they attend more to positive over negative information as a result of socioemotional changes that occur with age. Gain-framed messages were more effective in encouraging older adults to walk more ($t(58)=2.291, p<0.05$; $t(56)=2.23, p<0.05$). This change was linked to self-efficacy, such that participants with higher compared to lower levels of self-efficacy particularly decided to walk more after having received gain-framed information, whereas the level of self-efficacy did not make a difference for participants who had received loss-framed messages ($t(54)=2.158, p<0.05$). This supports the idea that in order to influence older adults' decisions, information framing has to match their emotional goals.

## SESSION 280 (SYMPOSIUM)

### AGEING & TECHNOLOGY: HOW THE USE OF TECHNOLOGIES CAN DEFINE, FULFIL & ENHANCE LIVING, WELL-BEING & COGNITIVE MEMORIES

Chair: *H.R. Marston, Teesside University, Middlesbrough, North Yorkshire, United Kingdom*

Discussant: *H. Moody, AARP, Washington DC, Washington*

The symposium will address the typology of technologies from philosophical perspectives, paradigms versus inflection points in describing and understanding the evolving, growing use and roles of technology in the ageing process and ageing experience. Furthermore concepts which digital technologies are being used to develop artefacts to aid older adults to document their lives which in turn may support and share the recall of memories of childhood by individuals with family members, thus building upon intergenerational relationships and in addition stimulate cognitive decline. Reminiscence through digital technology can support all individuals concerned and potential tailor built developments for the individual can create and shape positive emotions, memory, engagement and enjoyment through communication with the developer, family and friends. The digital medium of video gaming has been researched in recent years through a variety of works, bringing gaming and ageing together for the benefit of a current and future ageing population is an area which requires and crosses over into many disciplines to formulate and comprehend the wider picture. Research projects implementing digital technologies and software for the development of virtual environments and games has the potential to reward an optimistic therapeutic response in individuals. It has been suggested, software such as the Nintendo Brain Age has the ability, through training to aid mild/short term cognitive impairment, yet this is still a young notion and requires further studies. This concept has the notion of contributing a positive affect to a person's quality of life, cognitive stimulation, reaction time and enjoyment of individual(s).

### TOWARD "POST-AGING": THE VARIOUS ROLES OF TECHNOLOGY IN AN AGING SOCIETY

S.D. Wright, K. Felsted, *Gerontology Program, University of Utah, Salt Lake City, Utah*

This presentation will offer a typology for understanding the emergent and expanding role of technologies that hold both promise and peril for transforming the aging process in this century. This presentation is for participants who wish to review the continuum of varied intersects and constructs of technologies, that range from purporting to enhance the "activities of daily living" in older adults to those that propose to extend longevity and make senescence negligible, and ultimately claim to transcend "aging" itself - moving toward a transhumanist domain. It is proposed that we have reached critical mass in both the literature and in technological outcomes, and therefore, we can begin to address the actual and speculative impacts on the aging experience. It is further claimed that advances in technology has already - and will further - affect the epistemology and ethics, the expectations and educational practices for the aging experience in our lifetime.

### PROJECT SENELUDENS: MAINTAINING ANTICIPATORY CHARACTERISTICS FOR QUALITY OF LIFE IN THE AGING

M. Nadin, *AT 10, ante-Institute for Research in Anticipatory Systems, Richardson, Texas*

The hypothesis informing this work is that aging entails a decrease in the anticipatory characteristics needed for independent life. To mitigate the consequences of reduced anticipatory performance, brain plasticity is addressed through games. The perspective of anticipatory processes for evaluating specific gaming needs of the aging and providing games with anticipatory features will be introduced. Since anticipation is expressed in action, the games conceived, designed, and produced for triggering brain plasticity need to engage the sensory, cognitive, and motoric. The AnticipationScope, i.e., integration of motion-capture data and physiological sensors, is the quantifying platform for identifying individual characteristics and for validating the results of game participation. The output is the Anticipatory Profile. Implementations inspired by this original scientific framework are presented. This presentation will 1) inform the audience of an often unknown aspect of aging; 2) enable them to define goals in mitigating the effects of aging.

### DIGITAL MEMORIES: USING TECHNOLOGY TO CREATE REFLECTIONS OF LIFE AS PART OF THE AGEING PROCESS

J. Samuels, *Film and Media, Sussex University, Brighton, United Kingdom*

Digital media technologies can be used to document the life course of individuals' at different points during the lifecycle of human existence – life, death and afterlife as digital stories. This paper highlights the importance of preserving the past through the documentation of life as a digital artefact of an elderly artist in the form of a treasure chest, part for the public to enjoy her art but more as a legacy for her family to interact with and enjoy. The collation of symbols to represent the individual's life might also be viewed as a gift bestowed to future generations. After attending this symposium, participants will be able to explore the artefact and gain an insight into the therapeutic process of creating a digital memory as a documentation of life. In addition delegates will understand further how digital technologies can aid individuals both practitioners, users and carers' through the ageing process.

## SESSION 285 (SYMPOSIUM)

### ASSESSMENT IN ENVIRONMENTS FOR OLDER ADULTS

Chair: *H. Chaudhury, Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada*
Discussant: *J.A. Sanford, Georgia Institute of Technology, Atlanta, Georgia*

Environmental assessment/evaluation feed into practice decisions, provides research directions and informs conceptual understanding of the built environment's role in older adults' behaviors and experiences. The primary objective of this symposium is to present recent advances in assessment research in environments for older adults. The collection of studies represents multiple settings (e.g., home, neighbourhood, dementia care setting), functioning abilities (e.g., high functioning older adults, persons with cognitive loss) and the associated realities. The study by Gretchen and colleagues employed a community participatory approach engaging older adults in assessment of neighbourhood walkability in Portland, Oregon. This study raises the potential variation or divergence in environmental assessments conducted by experts and older adult. Chaudhury and Cooke will introduce the newly developed physical environmental assessment component of the well-known dementia care assessment and practice development tool Dementia Care Mapping (DCM). The new tool substantially expands the scope of the existing DCM incorporating coding schemes that identify possible environmental influences on observed behaviours in persons with dementia. In the following study, Oswald and colleagues address housing accessibility and control belief issues in very old age. Although the complexity of interrelations between and assessment of objective and perceived person-environment measures and quality of life has been acknowledged in the literature, very little empirical research has been conducted in this area. The final study by Teaford and Zavotka presents a comprehensive assessment tool to evaluate universal design aspects in the home environment. The study presentations will lead to a discussion on ongoing challenges in theory, methods and practice.

### OLDER ADULT VOLUNTEERS CONDUCTING ASSESSMENTS OF NEIGHBORHOOD WALKABILITY: PROCESS AND PRACTICAL IMPLICATIONS

G. Luhr, M.B. Neal, J. Dill, D.A. Lund, A. Adkins, V. Shandas, *Portland State University, Portland, Oregon*

Environmental assessments of the physical and social contextual features of neighborhoods that may both inhibit and promote physical activity have been increasing in popularity as data in gerontological studies. Assessing the features of residential neighborhood environments that are thought to promote physical activity may be important for encouraging active aging. We present the process utilized for implementing an assessment of the walking environment in four Portland, Oregon neighborhoods, particularly the inclusion of older adults (55+ years) as volunteer research assistants for completing the assessments. The project's advisory council, which was composed of representatives of stakeholder organizations, made suggestions regarding recruitment of older volunteers and aided in the distribution of recruitment materials. This presentation showcases the volunteer recruitment process, training protocol, findings regarding the reliability of volunteers' ratings as compared to project staff's, and practical recommendations for future studies wishing to involve older adults as volunteer research assistants.

### DEVELOPMENT OF A PHYSICAL ENVIRONMENTAL COMPONENT OF DEMENTIA CARE MAPPING (DCM-ENV)

H. Chaudhury[1], H.A. Cooke[2], *1. Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada, 2. University of Victoria, Victoria, British Columbia, Canada*

The physical environment of people with dementia is considered an important contributor to psychosocial, behavioral, and health outcomes in institutional settings. Dementia Care Mapping (DCM) is a valid tool for evaluating quality of life for people with dementia from a person-centered care philosophy. However, a major limitation of DCM is it does not contextualize the observed behaviors with the features and aspects of the physical environment of a care setting. This study is based on the development of an evaluative component for the physical environment (DCM-ENV) to be integrated within the current DCM tool. DCM-ENV strengthens DCM by grounding residents' behaviors and quality of care indicators in the built environment of the setting, and identifying areas for positive environmental modifications. Results from the pilot testing of the DCM-ENV will be presented.

### WHO IS IN CHARGE HERE? THE ROLE OF ACCESSIBILITY PROBLEMS AND HOUSING-RELATED CONTROL BELIEFS IN VERY OLD AGE

F. Oswald[1], H. Wahl[2], O.K. Schilling[2], S. Iwarsson[3], *1. Interdisciplinary Ageing Research, Faculty of Educational Sciences, Goethe University Frankfurt, Frankfurt, Germany, 2. Institute of Psychology, Dept. of Psychological Ageing Research, University of Heidelberg, Heidelberg, Germany, 3. Dept. of Health Sciences, Faculty of Medicine, Lund University, Lund, Sweden*

To comprehensively address person-environment relationships, the objective environment and the subjective experience of the setting need to be assessed. Our aim is to analyze the role of the magnitude of accessibility problems (MAP) at home and external housing related control beliefs (HCB) for outcomes of quality of life (e.g., ADL, depression). Data were drawn from the European project ENABLE-AGE survey study including 847 single-living and community-dwelling individuals aged 80 to 89 years (at T1) in urban regions in Sweden and Germany, 636 of whom were re-assessed one year later (T2). Cross-sectional analyses showed that MAP and HCB were consistently associated with quality of life outcomes. In the longitudinal analysis, MAP at T1 was predictive for T1-T2 change in ADL and depression, while HCB did not show substantial relations with any change in outcomes. Our study underlines the importance of understanding relations between objective and perceived person-environment measures and quality of life in very old age.

### APPLYING UNIVERSAL DESIGN AND HEALTH TO HOME ASSESSMENTS

M.H. Teaford, S. Zavotka, *The Ohio State University, Columbus, Ohio*

When considering relocation or aging in place, older adults need tools that include both a personal assessment and an assessment of the home in order to make decisions about future housing. The authors developed a survey based on Andes and Beamish (2005) which includes a) 50 item personal assessment of abilities, health status, services received, prior modifications to the home, changes in activities, demographic data, and homeownership/house; and b) 183 item home assessment that identified universal design features for 3 entrances, hallways and stairs, living area, kitchen, 2 bathrooms, 2 bedrooms, and laundry. From the results, total universal design score and subtotal scores for safety, accessibility, and convenience were calculated. Final scores were adjusted with negative points for missing key accessibility and safety features such as a first floor bath, stairs, and lack of handrails. They will discuss how results can be used to predict interest in making home modifications.

## SESSION 290 (SYMPOSIUM)

### COGNITIVE AND PSYCHOSOCIAL DETERMINANTS OF AWARENESS OF IMPAIRMENT IN EARLY-STAGE DEMENTIA

Chair: *L. Clare, Bangor University, Bangor, Gwynedd, United Kingdom*
Co-Chair: *R.G. Morris, Institute of Psychiatry, King's College London, London, United Kingdom*
Discussant: *M. Martin, University of Zurich, Zurich, Switzerland*

Awareness can be conceptualised as the accuracy with which a person appraises his/her functioning and situation. Disturbances of awareness are common even in early-stage dementia, and appear to develop through an interaction between cognitive decline and psychosocial factors. It is important to try to identify the relative contribution of cognitive, psychological and social factors to disturbances of awareness, and to understand the implications for care. This symposium reports initial findings from the Memory Impairment and Dementia Awareness Study (MIDAS), a comprehensive, longitudinal, multi-method approach to exploring awareness in early-stage dementia. Participants were 101 individuals with early-stage Alzheimer's (n=50), vascular (n=31) or mixed (n=20) dementia (mean age 78.66 years; mean MMSE score 24.17). People with dementia (PWD) completed questionnaire measures, experimental tasks, neuropsychological tests and an in-depth interview. Carers provided informant ratings, completed questionnaires, and engaged in an in-depth interview. Awareness of functioning was assessed in relation to memory, activities of daily living, and social behaviour, using participant-informant discrepancy measures. Awareness of performance was assessed in relation to memory by comparing participant post-dictions with objective test scores. Linda Clare's talk will discuss the relative contribution of neuropsychological, psychological and caregiver factors to scores on discrepancy measures of awareness. Robin Morris will focus on the association between awareness and neuropsychological functioning. Sharon Nelis will outline findings regarding awareness of social and emotional functioning. Anthony Martyr will present evidence to show that awareness may be retained at an implicit level in the absence of explicit awareness. Implications for care will be discussed.

### TESTING A BIOPSYCHOSOCIAL MODEL OF AWARENESS IN EARLY-STAGE DEMENTIA

L. Clare[1], S. Nelis[1], A. Martyr[1], I.S. Markova[2], I. Roth[3], R.T. Woods[1], C.J. Whitaker[1], R. Morris[4], *1. School of Psychology, Bangor University, Gwynedd, United Kingdom, 2. University of Hull, Hull, United Kingdom, 3. Open University, Milton Keynes, United Kingdom, 4. Institute of Psychiatry, King's College London, London, United Kingdom*

The relative contributions of neuropsychological, psychological, and caregiver factors to scoring on measures of awareness were explored with the aim of identifying predictive variables. Awareness of functioning was assessed in relation to memory, activities of daily living, and social behaviour using participant-informant discrepancy measures. Awareness of performance was assessed in relation to memory by comparing participant post-dictions with objective test scores. People with dementia also completed questionnaire measures and a brief neuropsychological battery. Carers provided informant-ratings and completed questionnaires assessing their own well-being. Discrepancies were substantial in the domain of activities of daily living, moderate for memory and slight in relation to socio-emotional functioning. Different combinations of variables predicted discrepancies in each domain. The results support a biopsychosocial model of awareness, indicating that scores on discrepancy measures in different domains are significantly predicted by varying combinations of individual psychological, neuropsychological and caregiver variables.

### NEUROPSYCHOLOGICAL CORRELATES OF AWARENESS OF COGNITIVE OR BEHAVIOURAL DYSFUNCTION IN EARLY-STAGE DEMENTIA

R. Morris[1], L. Clare[2], S. Nelis[2], A. Martyr[3], I. Roth[4], I.S. Markova[1], R.T. Woods[2], C.J. Whitaker[2], *1. Institute of Psychiatry, Kings College London, London, United Kingdom, 2. Bangor University, Bangor, United Kingdom, 3. University of Hull, Hull, United Kingdom, 4. Open University, Milton Keynes, United Kingdom*

The association between neuropsychological impairments and loss of awareness of neuropsychological or behavioural difficulties in early-stage dementia was explored with reference to the CAM model which outlines different neurocognitive mechanisms underlying disturbances of awareness. Awareness of memory loss was investigated in 101 people with early-stage dementia, using the MARS procedures, with a battery of neuropsychological tests to explore executive function, memory, language and semantic memory. For the MARS awareness of memory function procedure worse performance on the Rey AVLT, GNT, Category fluency and SART errors of commission were associated with lack of awareness. For the MARS memory performance awareness procedure, the associations were with the Rey AVLT, GNT and the Pyramids and Palm Trees. Deficits in episodic and semantic memory and attention may contribute to loss of awareness of cognitive dysfunction. Awareness may be influenced by method of measurement when rating the performance of people with dementia.

### AWARENESS OF SOCIAL AND EMOTIONAL FUNCTIONING IN EARLY-STAGE DEMENTIA AND IMPLICATIONS FOR CAREGIVERS

S. Nelis[1], L. Clare[1], A. Martyr[1], I.S. Markova[2], I. Roth[3], R.T. Woods[1], C.J. Whitaker[1], R. Morris[4], *1. Psychology, Bangor University, Bangor, United Kingdom, 2. University of Hull, Hull, United Kingdom, 3. The Open University, Milton Keynes, United Kingdom, 4. King's College London, London, United Kingdom*

Impairments in social and emotional function are a feature of early-stage dementia. This study explores the extent to which awareness of social and emotional function is also reduced, and whether this has an impact on the quality of life of the person with dementia (PwD), the quality of the dyadic relationship between PwD and carer, and carer levels of stress. People with dementia rated their ability to recognize emotions, show empathic reactions and appropriate behavior in social situations. Carers gave parallel ratings and an adjusted discrepancy score provided an index of awareness. Neuropsychiatric symptoms, quality of life in the PwD and carers, the dyadic quality of the relationship and stress in the carer were also assessed. People with dementia tended to overestimate their socio-emotional functioning. Reduced awareness was related to poorer perceived quality of relationship for the carer and greater carer distress.

### THE EMOTIONAL STROOP EFFECT FOR MEMORY-RELATED WORDS IN PEOPLE WITH DEMENTIA AND THEIR CAREGIVERS: INVESTIGATING THE IMPLICIT AWARENESS SYSTEM

A. Martyr[1], L. Clare[1], S. Nelis[1], J.L. Roberts[1], I.S. Markova[3], I. Roth[2], R.T. Woods[1], R.G. Morris[4], *1. Bangor University, Bangor, United Kingdom, 2. Open University, Milton Keynes, United Kingdom, 3. University of Hull, Kingston upon Hull, United Kingdom, 4. Institute of Psychiatry, King's College, London, United Kingdom*

This study explored whether people with dementia (PwD), and their carers, show a processing bias to dementia-related words in an emotional Stroop task, and whether the presence of such a bias is related to level of explicit awareness of the condition in the PwD. Seventy-nine PwD and 85 caregivers participating in MIDAS completed an emotional Stroop task. Time taken to colour-name dementia-related and neutral words was compared within and between groups. Ratings of explicit awareness shown by PwD, made on the basis of a detailed interview with each PwD and his/her carer, provided an index of explicit awareness. Both PwD and carers showed increased response times to salient compared to neutral words. In the PwD this effect was unrelated to degree of explicit awareness of the condition. The results indicate that preserved implicit awareness of the condition can be elicited in PwD even where there is reduced explicit awareness.

## SESSION 295 (SYMPOSIUM)

### DIFFERENCES IN HEALTH IN LATER LIFE: HOW IMPORTANT ARE COUNTRY LEVEL INFLUENCES?

Chair: *G. Ploubidis, London School of Hygiene & Tropical Medicine, London, United Kingdom*

Objectives: To investigate country level variation in later-life somatic health in Europe and the extent to which this is accounted for by policy related – and thus amenable to change- indicators. Methods: We employed data from 14 European countries included in the second SHARE measurement wave (N = 33,576). Results: Twenty percent of the variation in later life somatic health in Europe appears to be due to country level differences. Older people in the Scandinavian countries along with Germany, the Netherlands and Switzerland appear to have the best somatic health, whereas those in Spain, Italy and Poland have the worst. This country level variation was largely associated with differences in the level of egalitarianism of each country as well as differences in the prevalence of obesity within each country. Discussion: A substantive amount of systematic macro level variation in later life somatic health in Europe appears to be amenable to change.

### VARIATIONS IN HEALTH CARE UTILIZATION IN EUROPE: A MULTILEVEL ANALYSIS

Z. Or[1], F. Jusot[2,1], N. Sirven[1], *1. IRDES, Paris, France, 2. LEGOS, Uni. Paris-Dauphine, Paris, France*

Objective: to explore the role of health-care systems and individual socio-economic characteristics in health-care utilization. Methodology: Data from SHARE and the British Household Panel Survey are employed. Multilevel binominal models examine the country-specific effect of selected utilization measures on health care utilization. Differences in national health-care systems are tested to explain country specific effects. Finally, a multilevel model considers the impact of health care systems on the influence of individual socio-economic characteristics on utilization. Results: The results suggest that the organization and the modes of financing health care have an impact on both the level of health care utilization and the degree of inequity in utilization. The GPs position in the system, the organisation of primary care and cost sharing arrangements are particularly important. Discussion: The analysis clarifies the contribution of health care systems to national differences in health care utilization and to cross-country differences in social inequalities in utilization.

### TRANSITIONS IN FORMAL AND INFORMAL CARE UTILIZATION: A EUROPEAN ANALYSIS

J. Geerts[1], K. Van den Bosch[2], *1. Federal Planning Bureau, Brussels, Belgium, 2. Centre for Social Policy, University of Antwerp, Antwerp, Belgium*

Objective: To explore how long-term care systems influence formal and informal care utilization dynamics. Method: The sample includes persons 65+ from 11 European countries, participating in SHARE wave 1 and 2 (N=7,769). The effects of changes in health and in household composition on formal and informal care transitions were estimated, allowing these effects to vary across countries. Results: In all countries, formal and informal care are more often complements than substitutes. The likelihood of becoming a formal or informal care user differs significantly between countries. In the Scandinavian and Continental European countries the transition to formal care is more strongly related to informal support unavailability. We found little evidence of country differences in the effect of health variables. Discussion: Findings suggest a common trend towards targeting of formal services to single persons. We will discuss the consequences of this for the quality of life of elderly persons and their carers.

### SUPPORT TO OLDER PEOPLE, GENDER, AND THE WELFARE STATE

M. Brandt[1], K. Haberkern[2], T. Schmid[2], *1. MEA, University of Mannheim, Mannheim, Germany, 2. Institute of Sociology, University of Zurich, Zurich, Switzerland*

Aim: This study examined the societal organization of instrumental help and personal care to older people in Europe. It considered the influence of contextual structures on inter-generational support and the effect of these features on gender (in)equality. Method: Intergenerational support was regressed on contextual factors such as family obligations, social service supply, and female labor market participation. Control variables included opportunity, need and family structures. Results: Distinct differences were found between the types of support examined. Contextual structures influenced intergenerational transfers. Both crowding in and crowding out were seen, depending on the type of support. The analyses also showed that professional services reduce gender inequality in inter-generational support. Discussion: The findings support the specialization hypothesis in which family and state collaborate, taking on different tasks. They also show that family norms preserve gender inequality in informal support, whereas a developed welfare state contributes to greater equality.

### DIFFERENCES IN HEALTH SERVICES UTILIZATION AMONG DEPRESSED AND NON-DEPRESSED ELDERS IN EUROPE

K. Ladin, *Health Policy, Harvard University, Cambridge, Massachusetts*

Objective: I examine the influence of prevalence versus impact of covariates (demographic, socioeconomic, geographic, chronic disease, self-reported health, etc.) on differences in health services utilization between depressed and non-depressed respondents. Methods: Sample includes 31,115 respondents, aged 50+, in 11 countries (SHARE, Wave 1 Release 2, 2004). Blinder-Oaxaca decomposition methods for multivariate linear regression models were used to examine the influence of prevalence and impact of covariates on utilization. Results: The prevalence effect accounted for 57.7% of the utilization gap, whereas the impact effect explained 42.3%. Despite differences in quality and coverage of health services, in all countries the prevalence effect was explained entirely by need based factors. The impact effect varied cross nationally, but was entirely explained by enabling factors, particularly socioeconomic status and urbanity. Discussion: Gaps remain in understanding how to mitigate disparities in utilization among depressed persons. Increasing screening and depression treatment could mitigate disparities in most countries.

## SESSION 300 (POSTER)

## DEMENTIA

### TRAINING NURSING HOME RESIDENTS WITH DEMENTIA TO SERVE AS GROUP ACTIVITY LEADERS: PRELIMINARY RESULTS OF A RESEARCH STUDY

M.J. Skrajner, C. Camp, J.L. Haberman, *Hearthstone Research and Development, Willoughby, Ohio*

In an ongoing NIMH-funded research study, nursing home activity staff members are learning how to train residents with dementia to lead small-group activities for other residents. Researchers are measuring the extent to which residents can fill the role of group leader, and gauging the effects of resident-led activities on the engagement/affect of resident-players. Two programming methods are being used: Montessori Programming (MP-experimental) and Zgola Programming (ZP-control). To date, activity staff members have trained four nursing home residents to be leaders (two for each programming type). Thirteen participants have taken part in resident led-activities (seven MP participants and six ZP participants). Most resident-leaders and players have moderate levels of dementia. Residents have been able to serve as leaders for both programming types with some staff assistance. For MP, 82% of sessions have required less than 1 minute of assistance. For ZP, 25% of sessions have required less than 1 minute of assistance. For both programming types, engagement of participants has been greater in resident-led activities, as compared to baseline, standard activities. In particular, there have been significant increases in Constructive Engagement (CE; $\underline{p}<.01$) and decreases Non-Engagement (NE; $\underline{p}<.05$). CE showed a significantly greater increase from baseline in MP than in ZP. A significant increase in Pleasure ($\underline{p}<.05$), as compared to baseline, was observed in ZP, but was not observed in MP. Persons with dementia are capable filling meaningful social roles even after being placed in nursing homes, and these results can be obtained through programs created by nursing home staff.

### SEEKING COMMON GROUND: UNDERSTANDING MEANING MAKING AMONG FAMILY CAREGIVERS AND PERSONS WITH AD

J. Small[1], M.B. Fried-Oken[2], *1. College of Medicine, UAMS, Little Rock, Arkansas, 2. Oregon Health and Sciences University, Portland, Oregon*

Background: Propositional grounding is the coordinated process where the speaker/addressee dyad updates common knowledge on a moment-by-moment basis to create shared meaning. Method: A descriptive cross-sectional study was conducted to describe the types of grounded propositions produced by dyads composed of family caregivers (FCG) (n=24) and persons with AD (P-AD) and elders with no dementia and conversational partners (CP) (n=20).. Participants were recruited from the patient database at Oregon Health and Science University Alzheimer's disease Center. Participants selected a topic and engaged in three 10-minute videotaped conversations. The data was analyzed using a conversational analysis protocol. Results: FCG/P-AD dyads when compared to elder/CP dyads, were only able to ground 62.94% vs. 83.26% of their utterances. Nine percent (9.26% vs. 8.65% elder/CP) of P-AD/FCG utterances were facilitated-grounded and (16.89% vs. 11.87% elder/CP) of utterances were not grounded. FCG/P-AD in contrast to elder/CP dyads, used main and collateral track language behaviors to ground propositions. Under main track signals, 78.74% of P-ADs' vs. 94.15% of elders' utterances were maintained. Eighty-two percent (82.21% vs. 93.38 elders') of P-ADs' turns were filled. Among collateral track signals, 8.67% of P-ADs' turn contained overlapping or interrupted turns and 7.69% of P-ADs' vs. 0.15 of elders' turns were abandoned/no-response. Eighteen (18.32% vs 0.46% elder) of the utterances produced by P-ADs contained no referent. Forty-three (43.77%) of P-ADs vs. 8.31% of elder's utterances contained some type of trouble indicating behavior. Main study findings indicate that FCG + P-AD conversations were markedly different from the conversations of the contrast group.

### MATCHED AND MISMATCHED APPRAISALS OF THE EFFECTIVENESS OF COMMUNICATION STRATEGIES BY FAMILY CAREGIVERS

M.Y. Savundranayagam[1], J.B. Orange[2], T.L. Meyer[1], R.K. Garrett[1], *1. University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, 2. University of Western Ontario, London, Ontario, Canada*

Communication problems stemming from Alzheimer's disease (AD) often comprise breakdowns in information exchange which are linked with problem behaviors and increased caregiver stress. Communication breakdowns can result from caregivers' use of ineffective strategies which, paradoxically, are perceived as helpful. This study examined whether caregivers' appraisals of strategy effectiveness (survey data; N=84) were consistent with effective strategies found in the literature and in video-recorded mealtime conversations from a subsample (N=15) of AD family caregiver dyads. Conversations were analyzed using the trouble-source repair paradigm which identifies and assesses the effectiveness of caregiver communication strategies to resolve breakdowns. Effective strategies in the conversations which were appraised correctly by family caregivers included: "repeat", "simplify", "rephrase", and "try to figure out meaning". "Continue talking" was the only ineffective strategy in the conversations and appraised as such by caregivers. Discrepancies occurred between caregivers' appraisals of strategy effectiveness and assessments of strategy effectiveness using the video data and existing literature. Caregivers appraised "speaking slowly" as effective but the literature demonstrates the opposite influence. "Give more information", "ask to repeat", and "ask for clarification" were used frequently as effective strategies in the conversations but were appraised as less than moderately effective. Other strategies inaccurately appraised by caregivers as ineffective included: "write", "pretend to understand", "say 'I don't understand'", "give choices of what you think he/she means", "ask questions", and "gestures". Although caregivers correctly appraised the effectiveness of some strategies, instances of a mismatch illustrate the need for continued communication education and training.

### A PRINCIPLE-BASED CONCEPT ANALYSIS OF COGNITIVE REHABILITATION IN PEOPLE WITH DEMENTIA

N.L. Hill, *School of Nursing, Penn State University, University Park, Pennsylvania*

Non-pharmacological, cognition-based interventions for people with dementia have shown promise in their ability to improve functional status and quality of life outcomes. Although attempts have been made to differentiate the variety of intervention types, significant conceptual confusion persists in the scientific literature, particularly in regard to cognitive rehabilitation. A principle-based concept analysis was conducted to determine the current state of the science regarding cognitive rehabilitation in people with dementia. A comprehensive literature search was conducted in PubMed, CINAHL, PsycINFO, and the Cochrane Library. Data were evaluated according to the four key philosophical principles (epistemological, pragmatic, linguistic, and logical), resulting in a theoretical definition of cognitive rehabilitation in people with dementia: a holistic intervention that uses a variety of techniques to target a range of practical, person-centered outcomes, rather than cognition alone.

### EDUCATION AND DEMENTIA: A SYSTEMATIC REVIEW OF PUBLISHED STUDIES

E.S. Sharp, M. Gatz, *Psychology, University of Southern California, Los Angeles, California*

The purpose of this study was to conduct a systematic review of the literature on the relationship between education and dementia. A systematic literature review was conducted of all published studies examining the relationship between years of formal education and dementia listed in the PubMed and PsycInfo databases from 1990 to 2010. The inclusion criterion was dementia diagnosis by a published standardized diagnostic procedure. The two dementia outcomes included were Alzheimer's disease and any type of dementia combined. A total of 76 studies (from 67 articles) met inclusion criteria. Overall, 27 studies reported a significant effect of education on risk for dementia, 23 studies reported both significant and nonsignificant findings, and 26 studies reported no significant relationship. Geographical region moderated the results such that the effect of education on risk for dementia was more consistent in developed regions compared to developing regions. When studies compared multiple levels of education, the results were largely nonlinear such that no or low education levels were significant but middle levels of education were not significant. This finding suggests that more years of education alone may not attenuate risk for dementia. The results of this review indicate that the relationship between education and dementia may be less consistent than previously presented in the literature.

### DIFFICULT DIAGNOSES: EXAMINING CAREGIVERS EXPERIENCES WITH DEMENTIA DIAGNOSIS

A.K. Gibson, K.A. Anderson, *College of Social Work, The Ohio State University, Columbus, Ohio*

Memory loss disorders, such as Alzheimer's disease and other dementias, are difficult to diagnose and the information and support that individuals and families receive during and following such diagnoses is often incomplete and inadequate. In some cases, individuals and families can wait years to finally receive a definitive diagnosis, further hampering their ability to connect with disease-specific community resources, such as those offered through the Alzheimer's Association. The majority of the existing research that has been conducted on the diagnostic process for dementia has focused specifically on the role of the physician. As such, little is known regarding the needs of individuals with dementia and their family caregivers following this often devastating diagnosis. In this ongoing study, the researchers examine family caregivers' experiences during and after the diagnosis of dementia and the paths by which caregivers access information and community resources. In this presentation, the researchers will discuss their sampling strategies, methods for data collection, and initial findings from the study. Emerging strategies for improving the exchange of information during and following the diagnosis of dementia will also be introduced, as well as suggestions for enhancing the process of connecting caregivers to support services.

### HOW NURSES DECIDE TO PROVIDE ANALGESIC TREATMENT TO LONG TERM CARE RESIDENTS WITH DEMENTIA

A.L. Gilmore, B.J. Bowers, *University of Wisconsin-Madison, Madison, Wisconsin*

Nearly eighty percent of nursing home residents regularly experience pain that is either untreated or inadequately treated. Efforts to identify and treat pain are complicated by dementia. Research suggests that even when pain is identified in people with dementia, it is often treated less aggressively. However, little is known about the reasons for this inadequacy and the relationship between pain identification and decisions to treat. The purpose of this study was to examine what factors influence nurses' decisions to provide analgesic interventions and what processes they use to identify pain in people with dementia. This study consisted of interviews with nurses (n=8) from 3 nursing homes. Data were collected and analyzed using a qualitative research methodology, Dimensional Analysis. Results suggest that the number and type of strategies used by nurses to identify pain and the urgency with which they provide analgesic interventions varies based on different resident characteristics. Resident characteristics that nurses acknowledged as influencing identification of pain and subsequent analgesic intervention included type of pain (chronic/acute), type of resident (long term/short term), ability to communicate, and perception of drug-seeking behaviors. Nurses identified several barriers to prompt treatment after having identified pain. The results of this study have implications for future research aimed at addressing misconceptions about pain assessment and treatment in nursing homes.

### THE RELATIONSHIPS BETWEEN LEISURE ACTIVITY AND BEHAVIORAL PROBLEMS AMONG DEMENTIA PATIENTS

C.N. Huang, Y. Chiu, S. Lee, W. Hsu, C. Li, *Nursing, Chang-Gung University, Taoyuan, Taiwan*

Leisure activities were an effective intervention on behavioral problems for demented adults in Western countries. However, there are few related studies conducted in Taiwan. Objective: The purpose of this study was to explore the sum of leisure activity types, and Behavioral and Psychological Symptoms of Dementia (BPSD) among early to moderate demented patients in Taiwan. Method: It was a descriptive correlation study, recruiting 34 community-dwelling demented patients. Types of individual and group leisure activities in the past month were measured by the Restorative Activity Questionnaire (RAQ). BPSDs were measured by Neuropsychological Inventory (NPI). Result: The men and women ratio was 11/23 with a mean age 78.03 ± 8.64 and mean educational years 5.68 ± 5.48. The major diagnosis was Alzheimer's disease (n=33, 97.1%). The mean of leisure activity types was 5.73 ± 3.56; most of the cases did not participate in group leisure activities. The most participated individual leisure activities were: watching television (97%), walking (85.3%) and planting vegetables (52.9%). There was a significant gender differences in individual RAQ (t= -3.25, p=0.04). Individual RAQ was significantly and negatively correlated with delusion (r=-0.49, p<0.01), hallucination (r = -0.42, p = 0.01), excitement/aggression (r=-0.44, p<0.01), depression / bad mood (r = -0.45, p <0.01), and irritability /emotion (r = -0.42, p= 0.01). Conclusions: The study found that sum of individual leisure activity types was negatively correlated with patients' BPSDs. In the future, leisure activities can be an appropriate intervention for early to moderate dementia patients to reduce their BPSDs.

### DEMOGRAPHIC AND CONTEXTUAL FACTORS RELATED TO KNOWLEDGE ABOUT ALZHEIMER'S DISEASE

S.M. Zoller[1], B. Carpenter[1], M. Gatz[2], *1. Psychology, Washington University in St. Louis, St. Louis, Missouri, 2. University of Southern California, Los Angeles, California*

Accurate knowledge about Alzheimer's disease (AD) is essential for effective dementia care. This study examined knowledge among 794 people who completed the Alzheimer's Disease Knowledge Scale (ADKS; Carpenter, Balsis, Otilingam, Hanson, & Gatz, 2009) and questions about their background and experience with AD. Across the entire sample, knowledge about AD was fair (average proportion correct = 72%, $SD$ = 58% - 86%). Knowledge was highest for dementia professionals (91% correct), lower for older adults (80%) and dementia caregivers (76%), and the lowest for senior center staff (67%) and undergraduates (67%), $F(4,752) = 86.28, p <.001$. Respondents knew the most about assessment, treatment, and management (82% correct), less about caregiving (78%), prevalence, symptoms and course (77%), life impact and legal matters (74%), and the least about risk factors and prevention (62%). Knowledge about AD tended to increase with age ($r = 0.30$) and education ($F(2,422) = 68.60$). Other factors correlated with increased knowledge were having family members with AD, attending a related class or support group, working with AD patients, and acquiring information from professional sources rather than popular or personal sources. Those who had provided direct care to someone with AD were no more knowledgeable than those never providing direct care. Results from a multiple regression confirmed that demographic characteristics and exposure to information about AD had the most significant associations with knowledge about dementia. Understanding where gaps in dementia knowledge exist can guide education initiatives to increase disease awareness and improve supportive services.

### PREVENTING AGGRESSION IN VETERANS WITH DEMENTIA

S. Shrestha[1], A. Bradford[1,2], A. Snow[4], N. Wilson[1,2], M. Stanley[1,2,3], M.E. Kunik[1,2,3], *1. Houston Center for Quality of Care and Utilization Studies, Baylor College of Medicine, Houston, Texas, 2. Houston Center for Quality of Care and Utilization Studies, Houston, Texas, 3. Michael E. Debakey Veteran Affair Medical Center, Houston, Texas, 4. University of Alabama, Tuscaloosa, Alabama*

The prevalence of aggression among Veterans with dementia is estimated to be about 40%, and this condition often remains untreated (Kunik et al., 2007). There is a pressing need for more research on non-pharmacologic treatment of aggression in persons with dementia (PWD). A recent study on aggression in PWD showed that pain was the strongest predictor of aggression (Kunik et al., 2009). Among PWD, prevalence of pain is known to be about 50% (Sawyer et al, 2006). Therefore, better management of pain can be a preventative approach towards reducing aggression in PWD. Preventing Aggression in Veterans with Dementia (PAVeD) is a home-based, psycho-educational intervention for pain aimed at reducing the incidence and severity of aggression in community-dwelling Veterans who have mild to moderate dementia. PWD who have clinically significant pain have been recruited from both primary care and specialty clinics in the Michael E. DeBakey VA (Houston, Texas). The intervention is, directed to the caregiver and, to the extent possible, the PWD, consists of six skill-based visits that include information on recognition and treatment of pain, communication, and behavioral activation. The proposed poster will present the development of the treatment and the manual, and case examples from an ongoing pilot study.

### FIELD TESTING A BEHAVIORAL MEASURE OF EXCESS DISABILITY THROUGH AN UNDERGRADUATE TRAINING PROGRAM

C. Catlin, J. Fisher, C. Drossel, C. Rummel, C. Garrison-Diehn, *Psychology, University of Nevada Reno, Reno, Nevada*

This paper will describe a dementia care training program administered with an undergraduate geropsychology field experience course. The program is designed to promote the detection of excess disability in older adults with dementia. Undergraduate students receive training in a restraint free model of dementia care and the monitoring of normal and abnormal behavior change in verbally impaired older adults with dementia. Students then participate in weekly home visits with socially isolated persons with dementia. Individualized behavioral monitoring data are collected to assess any unexpected change in behaviors that have been historically frequent and stable (e.g., story-telling, smiling, or making eye contact). Preliminary data indicate that even subtle changes in adaptive behaviors often signal an acute medical, psychological, or environmental problem. Problem behaviors tend to emerge shortly after the change in adaptive behavior. The results of this study indicate that early detection of excess disability can significantly improve client care and outcomes.

### DISCOMFORT BEHAVIORS BETWEEN BLACK AND WHITE NURSING HOME RESIDENTS WITH CANCER AND DEMENTIA

T. Monroe, M. Carter, *Nursing, The University of Tennessee Health Science Center, Memphis, Tennessee*

Aims: The aim of this study was to determine if discomfort related pain behaviors were different between Black and White nursing home residents with dementia who died from cancer. Residents with dementia are often poorly able to report their pain levels and nursing stuff rely on pain behaviors for assessing pain and pain treatment. Methods: Decedent records from 2003-2009 were assessed for cause of death as cancer and diagnosis of dementia. Fifty-five decedents from 10 nursing homes in west Tennessee were included in the final sample. Three instruments were used: the Minimum Data Set (MDS), Cognitive Performance Scale (CPS), and Discomfort Behavior Scale (DBS). The study received exempt status from the office of human protection. Results: Mean DBS scores were significantly higher (p =.009; 95% CI 1.934 - 12.614) among Black nursing home decedents with cancer and dementia. Conclusions: We demonstrated that discomfort related pain behaviors among Black nursing home residents with dementia who died from cancer may be significantly higher than White residents. This study suggests that Black nursing home residents with dementia who die from cancer may be at increased risk for under treatment of pain.

### INDIVIDUALS WITH EARLY ONSET DEMENTIA AND THEIR CAREGIVERS: PROGRAM ACCEPTABILITY AND FEASIBILITY

S. Orsulic-Jeras, H. Menne, C.J. Whitlatch, S. Schwartz, J. Johnson, *Benjamin Rose Institute, Cleveland, Ohio*

In the United States there are approximately 500,000 individuals under the age of 65 who are living with dementia or Alzheimer's disease (Alzheimer's Association, 2009). These individuals and their families often report difficulty in getting a diagnosis, receiving appropriate medical care, and facing many barriers when trying to access services. This poster will describe the implementation of an intervention previously developed and tested with individuals with early to moderate stage dementia with typical onset (over the age of 65) and discuss the acceptability of this intervention by individuals with early onset dementia and their family caregivers. The goals of the Early Diagnosis Dyadic Intervention (EDDI) are to: -Help care partners develop positive communication patterns -Increase the care partners' knowledge and understanding of available services, care values, and preferences for care -Increase the individual with dementia's active participation in his/her care plan -Improve care partners' well being and sense of self-efficacy in managing disease related issues We will discuss the acceptability of the EDDI intervention for those diagnosed with early onset dementia. Important issues that arise when working with individuals with early onset dementia and their families include: 1) assessing each person's readiness to accept their diagnosis and/or the challenges they face; 2); tailoring the intervention to fit the dyad's current stage of acceptance; and 3) applying what is learned to their current challenges.

### HEALTH BEHAVIORS AMONG OLDER ADULTS WITH MILD COGNITIVE IMPAIRMENT

A. Gentry, G. Morgan, J.H. Lingler, *School of Nursing, University of Pittsburgh, Pittsburgh, Pennsylvania*

Background: Although no specific interventions have been show to prevent progression from Mild Cognitive Impairment (MCI) to dementia, anecdotal evidence suggests that clinicians may make various recommendations to affected individuals at the time of diagnosis. The purpose of this investigation was to characterize the range of health-related activities adopted by persons with MCI following diagnostic disclosure. Method: Sixty MCI participants were recruited from a memory disorders clinic and completed a one-time interview. Participants were asked about their intention to adhere to clinical recommendations and to report if they planned to adopt any further health-related activities as a direct result of their MCI diagnosis. Results: Clinical recommendations included returning for yearly follow-up cognitive testing (96.7%) and pharmacologic (73.3%) and nonpharmacologic (20.0%) treatments. Patients invariably reported a high degree of intention for adherence. Most patients (61.7%) also reported planning to adopt health-related activities that exceeded clinical recommendations. These included behaviors to minimize the impact of symptoms (e.g., cognitive stimulation or cueing and reminder systems) (55.0%), health promotion activities (e.g., physical activity and nutritional adjustments) (20.0%), and increasing general activity (e.g., socialization) (16.7%). Participants who were more likely to report adopting health behaviors that went beyond clinical recommendations were college educated (p<0.05), and had greater perceived control over their memory problems (p<0.001). Conclusion: Many MCI patients report intention to adopt protective behaviors in response to their clinical diagnosis in lieu of known therapies.

## ALTERNATING WORD FLUENCY IN DEMENTIA

S. Engel, R. Rupprecht, R. Mahlberg, *Institute of Psychogerontology, Friedrich-Alexander-University of Erlangen-Nuremberg, Erlangen, Germany*

There is broad evidence that already in the earliest stages of dementia the access to semantic knowledge, measured by tasks of semantic fluency is affected as well as the performance in set-shifting-tasks, e.g. on the Trail Making Test Part. We suppose that a combination of the switching task paradigm with semantic fluency could discriminate between persons with mild dementia and cognitively healthy persons more accurate than either task alone. The combination of set-shifting and categorical verbal fluency is called «alternating word fluency» (AWF). It requires the subject to recall words from two (or more) semantic categories strictly alternating in a given time (usually 60 seconds). N=138 (58.7% female; age; M=73.9; SD=7.03) patients of the Erlangen memory clinic were included in the study and diagnosed according to ICD-10 criteria to one of the following groups: subjective memory complainers (SMC; N=60 (43.5%); MMST: M=29.5; SD=.72); mild cognitive impairment (MCI; N=37 (26.8%); MMST: M=27.9; SD=1.13) and people with dementia, mostly SDAT (PWD; N=41 (29.7%); MMST: M=25.0; SD=2.92). The AWF-Score (number of correct switchings) correlates significantly with the MMSE-total score (r=.54, p<.001) as well as with MMSE subscores Orientation (r=.41, p<.001) and Recall (r=.53, p<.001). Furthermore an analysis of variance (ANOVA) revealed a significant main effect of diagnosis (F2;135=46.7; p<.001). Thus members of the three different diagnosis groups scored differently in the AFW-Test (SMC: M=16.5; SD=3.72; MCI: M=12.5; SD=4.00; PWD: M= 8.2; SD = 5.01). Ordinal logistic regression analysis confirmed the potential of the AWF-Test for early diagnosis of beginning dementia.

## THE EFFECT OF DEMENTIA EDUCATION PROGRAM ON NURSE AIDES IN KOREAN NURSING HOMES

E. Kong[1], Y. Seo[2], *1. Kyungwon University, Seungnam, Republic of Korea, 2. Seoul Junggye Senior Care Center, Seoul, Republic of Korea*

Korea faces the problems related to rapidly increasing dementia population, increasing demands of nursing homes, and low quality of service of nurse aides. However, there is no published study regarding the effects of dementia education program on nurse aides caring for older adults with dementia in Korean nursing homes. The aim of this study was to evaluate the effects of dementia education program on nurse aides caring for older adults with dementia in Korean nursing homes with regard to dementia knowledge, dementia care, work satisfaction, and work stress. A total of 24 nurse aides participated in dementia education program and were evaluated at four points in time: before the program, immediately after the program, 1 month after the program, and 3 months after the program. Nonparametric test statistics were used to test the effects of the education program. Significant changes of dementia care were found($\chi2$ = 13.37, p = 0.004). Although the program improved dementia knowledge, no significant change of dementia knowledge was found($\chi2$ = 5.036, p = 0.169). There were no significant changes in work stress($\chi2$ = 6.618, p = 0.085) and work satisfaction($\chi2$ = 0.090, p = 0.993). Results indicated that dementia education program had statistically significant effects on nurse aide's dementia care. As the first study to test the effects of dementia education program on nurse aides in Korean nursing homes, the results of this study will contribute to improving education for nurse aides in nursing homes.

## THE CHALLENGES OF KOREAN IMMIGRANT DEMENTIA CAREGIVERS' PARTICIPATION IN RESEARCH

E. Kong, *Kyungwon University, Seungnam, Republic of Korea*

There is a dearth of research on Korean immigrant caregivers of elders with dementia in American nursing home due to the difficulties of recruitment of Korean immigrant dementia caregivers. There has been, however, no published study which explored the challenges of Korean immigrant dementia caregivers related to participation in research. The purpose of the study was to describe Korean immigrant dementia family caregivers' experiences related to the participation in research. A purposive sampling method was used to recruit informants. Ten Korean immigrant dementia caregivers participated in in-depth interviews. Symbolic interactionism and cultural models were used as theoretical frameworks. Using Atlas-ti program, qualitative content analysis was used for data analysis. Seven themes emerged: busy life, family matter, multiple roles, face saving, cultural stigma, limited interaction, and lack of experience. This study provides increased understanding of the experience of Korean immigrant dementia caregivers related to the participation in research as informants. This study adds to the knowledge of recruitment and retention of Korean immigrant family caregivers of elders with dementia.

## AN OUNCE OF PREVENTION: ALZHEIMER'S DISEASE AND STRATEGIES FOR COGNITIVE HEALTH

L.G. Hodgson[1], S. Cutler[2], *1. Sociology, Quinnipiac University, Hamden, Connecticut, 2. University of Vermont, Burlington, Vermont*

Increasingly, Alzheimer's disease (AD) is seen as a public health issue. Although acknowledging that much remains unknown about the efficacy of measures to promote cognitive health, governmental and private organizations have been seeking to raise public awareness about the types of "healthy body/healthy mind" activities that may help to preserve cognitive functioning into old age and forestall dementia. Using data from a larger study on middle-aged persons' concerns about developing AD, this paper focuses on a descriptive analysis of the types of and reasons for prevention strategies employed by the sample. In 2000, Cutler and Hodgson conducted a baseline study of 258 middle-aged men and women on their personal concerns about developing Alzheimer's disease (AD). In 2005, 2nd wave follow-up data were collected from 80% of the original sample (N=206). Of those Wave 2 respondents who reported a concern about memory functioning, 57% reported that they had employed at least one strategy aimed at promoting cognitive health, with "exercise" (83%) and "dietary supplements" (73%) as the most frequent strategies. In subsequent follow-up interviews with a sub-sample of the respondents, the rationale for undertaking prevention measures was explored in depth. Grounded theory was employed to discern patterns and themes within the data. Major themes include the primacy of the media as a public health promotion tool and a growing acceptance of the connection between physical and mental well-being. Understanding how people are receiving and acting on the message of cognitive health promotion will help to guide efforts in the future.

## THE REPEATED APPEAL TO RETURN HOME IN OLDER ADULTS WITH DEMENTIA: DEVELOPING A MODEL FOR PRACTICE

S. Fukui[1], H. Nelson-Becker[1], S. Okada[2], Y. Nishimoto[3], *1. Department of Social Welfare, University of Kansas, Lawrence, Kansas, 2. Osaka City University, Osaka, Japan, 3. The Oyamada Nursing Home, Yokaichi Mie, Japan*

Dementia care has been trapped in a "trial and error" type of practice due to difficulty understanding the needs of older adults with severe dementia. Behavioral and Psychological Signs and Symptoms of Dementia (BPSD) can be quite difficult for residential staff. However, some experienced care workers succeed in establishing effective relationships. The goal of this study was to: 1) develop a process to identify needs behind BPSD; 2) find solutions using a team approach; and 3) apply the results to educate new workers. The K-J method was employed to reach decision-making about best practices in residential dementia care. This qualitative method is used to organize group data collected in the field and is based in understanding complex situations. A group process of 12 Japanese care workers experienced in understanding and responding to the "repeated appeal to return home" of residents in nursing care facilities is highlighted along with an illustrative case example. The workgroup met over two years. The study revealed five steps in understanding the needs behind the appeal, which include: (1) listen to the voice and go with the flow of the behavior; (2) learn about the inner experience; (3) learn about the contextual environment of "here and now" situations; (4) reflect on the care environment; and (5) find the keyword. This needs identification process has application to other cultural contexts. The implications of this study for practitioners who work with people with dementia in residential settings will be discussed.

## SESSION 305 (PAPER)

## END-OF-LIFE DECISION MAKING

### INTER-DISCIPLINARY TEAM'S ROLE IN END-OF-LIFE CARE FOR INDIVIDUALS WITH DEMENTIA

C.E. McCarty, D.J. Dobbs, V. Molinari, *School of Aging Studies, University of South Florida, Tampa, Florida*

Within Skilled Nursing facilities, End-of-Life (EOL) care for individuals with dementia is provided in three settings: Hospice care, Dementia Special Care (as expressed in Dementia Special Care Units) and traditional care. Both hospice and Dementia Special Care Units (DSCU) are models of care with improved outcomes. A strong Inter-Disciplinary Team (IDT) with unique disciplinary input are key to both models. Both include the patient and family as the central focus. Members of the IDT make the determination of which care level and plan is most appropriate for the needs of the patient. Family overall satisfaction in hospice care has been shown to rely on the impact of the IDT. Regular and accurate communication about the patient's medical condition, provision of adequate emotional support, and the identification of one nurse as being in charge of their loved one were linked to family satisfaction. Using Structure-Process-Outcome theory, this study analyzed the structure and process factors of hospice and DSCU versus traditional care to determine their association with better EOL care scores. Hierarchical regressions with Comfort at Death and Satisfaction with Care showed the process variables of hospice, DSCU enrollment and IDT offered significant contribution to the variance in outcome. Interactions of enrollment in hospice and Strength of IDT showed significance supporting the hypothesis that IDT is a moderator of the predictive value of hospice enrollment on both Satisfaction with Care and Comfort at Death. Interactions of enrollment in DSCU and Strength of IDT showed significance with IDT also being the moderator.

### EFFECT OF TRUST IN PHYSICIANS AND CAREGIVER BURDEN ON END-OF-LIFE TREATMENT DECISIONS MADE BY AFRICAN AMERICAN DEMENTIA CAREGIVERS

G. Bonner, Y.J. Watkins, E. Wang, D.J. Wilkie, C. Ferrans, B. Dancy, *Biobehavioral Health Science, University of Illinois at Chicago, Chicago, Illinois*

Trust in physicians and caregiver burden are important concepts, but it is unknown if they influence end-of-life treatment decisions made by African American (AA) surrogates. Purpose: A pilot study was conducted to explore associations among trust in physician, caregiver burden and demographic characteristics on cardiopulmonary resuscitation (CPR), mechanical ventilation (MV) and tube feeding (TF) treatment decisions made by AA dementia caregivers. Methods: In a cross-sectional design, a battery of standard measures was administered in group sessions to a convenience sample of 68 AA dementia caregivers. Univariate and multivariate analyses were used to explore associations among the variables. Results: Caregivers reported relatively high trust (150±24, range 38-190) and moderate burden (31±8, range 12-60) scores. Male caregivers reported lower trust (144±27 vs. 151±23, respectively) and burden (29±7 vs. 31±9, respectively) scores than female caregivers. Caregivers with lower income (>$25,000) also reported lower trust (142±28 vs. 152±23, respectively) and higher burden scores (33±9 vs. 30±9, respectively). College graduates exhibited the lowest trust (139±25) and highest burden (38±9) scores. Shorter length of caregiving and severe disability of care receiver also resulted in higher reported burden scores. Although caregivers with higher burden and lower trust scores were more likely to make a decision to use CPR, MV, and TF for their care receivers, the differences were not significant in either univariate or multivariate analyses. Conclusions: Although not statistically significant, trends indicate that trust in physicians and caregiver burden are important factors to consider when planning interventions for AA dementia caregivers.

### TESTING A STRUCTURED PALLIATIVE CARE INTERVENTION IN THE NURSING HOME

J.P. Reinhardt, E. Chichin, L. Posner, *Research Department, Jewish Home Lifecare, New York, New York*

End-stage dementia is characterized by progressive cognitive and physical decline compounded by co-morbidities and increasing frequency of acute events. Patients' families need to make treatment decisions regarding interventions (artificial nutrition, hospitalization), often without adequate knowledge/support. Medical technologies may be used with patients with advanced dementia, yet much literature recommends avoiding them due to limited benefit and significant discomfort for patients. Families need education about potential benefits and burdens of interventions to make informed decisions. This paper presents results of an exploratory, randomized trial of a structured palliative care intervention versus a usual care control with social contact (50 per group) for nursing home residents with advanced dementia and their health care proxies (HCP). The intervention included an initial one hour meeting of the HCP and palliative care team (review care goals; work to achieve goals), followed by regular telephone contact with the HCP and resident visits. Telephone interviews are conducted with HCPs at baseline, 3 and 6 months later. Data from the 3-month follow-up are presented. Average age was 84 for residents (78% female) and 57 for HCPs (89% female). Residents were ethnically diverse with 45% African American, 33% Hispanic, and 22% Caucasian. HCPs were children (64%), other relatives (19%), spouses (11%), and friends (6%). Preliminary results showed that HCPs in the structured palliative care intervention group reported better outcomes for their elder relatives (e.g., better symptom management) and better outcomes for themselves (e.g., less perceived stress) compared to the usual care control group. Practice applications are discussed.

### THE RELUCTANCE TO BURDEN OTHERS AS A FACTOR IN END-OF-LIFE DECISION MAKING: DIFFERENCES BETWEEN ELDERS AND THEIR PROXIES

L. Winter, S.M. Parks, *Thomas Jefferson University, Philadelphia, Pennsylvania*

Most US patients are decisionally incapacited at the end of their lives, leaving final treatment decisions to proxies, usually family members. Unfortunately, proxies' subsituted judgment about elders' treatment preferences is often inaccurate. We explored reluctance to burden others (RB) as a factor in decision making about end-of-life (EOL)treatments among elders and their proxy decision makers and also examined RB as a possible source of proxy inaccuracy in substitued judgment EOL care preferences. Two hundred two elderly men and women responded to 3 questions about burdening others (emotional and financial burden and desire to be independent) and the Life-prolonging Treatment Preferences Questionnaire, and their designated proxies responded to the same questions using substituted judgment. Although RB predicted treatment preferences for both elders and proxies, it was significantly higher among elders than proxies, and RB differences between elder-proxy dyads were associated with elder-proxy discordance in EOL treatment preferences.

### SELF-PERCEIVED BURDEN: ITS ANTECEDENTS AND ASSOCIATION WITH ADVANCE CARE PLANNING

J. Hash-Converse, S. Bodnar-Deren, E.L. Idler, E.A. Leventhal, H. Leventhal, *Institute for Health, Health Care Policy, and Aging Research. Center for the Study of Health Beliefs and Behaviors, Rutgers, The State University of NJ, New Brunswick, New Jersey*

The extent to which a care recipient believes they are a burden may negatively affect treatment adherence, the use of end-of-life (EOL) medical interventions, and EOL decision-making. Since the co-occurrence of chronic conditions (Chronic Illness with Complexity, CIC) is increasingly prevalent (~65% of those +65 years) and problematic in the elderly, we postulate that CIC will relate to self-perceived burden (SPB) and the likelihood of making EOL plans. Using logistic regression, we found that for every increase in number of comorbidities, the odds of SPB increases by 50% (controlling for race), and self-perceived burden increases odds of engaging in advance care planning (ACP) for health. Further, the number of comorbidities explains 9.6% of variance in SPB. Understanding how CIC relates to burden may be the gateway by which physicians can initiate meaningful EOL conversations.

# SESSION 310 (PAPER)

## GERIATRIC AND GERONTOLOGICAL TRAINING

### EXAMINING A NEW GENERATION OF GERONTOLOGISTS: AN ANALYSIS OF GERONTOLOGY DOCTORAL STUDENTS

D.C. Carr[1], H. Ewen[2], *1. Scripps Gerontology Center, Oxford, Ohio, 2. Miami University, Department of Sociology and Gerontology, Oxford, Ohio*

Until recently, individuals who study aging have been trained in traditional disciplines. Over the last two decades, a growing number of interdisciplinary doctoral programs in gerontology have emerged, and are producing a new interdisciplinary scholar. At a time when aging research is gaining broader attention, it seems timely for the field of gerontology to examine the unique characteristics of this generation of “gerontologists.” In this presentation, we report results from four cohorts of doctoral students from all gerontology doctoral granting institutions in the United States who have participated in the Gerontology Education Longitudinal Survey (GELS). Specifically, we examine the educational and demographic characteristics of doctoral students, the training they are receiving, their career aspirations, and the types of scholarship they are producing. Analysis of these data reveals three dominant types of doctoral students who are studying gerontology: The first type includes individuals with social science and gerontology backgrounds seeking academic or research careers in gerontology ; The second type are those who have experience working with older adults in practical or applied settings with goals of securing employment in government or the private sector; The third type includes individuals with educational backgrounds in traditional disciplines and who plan to return to traditional disciplines upon completion of their education. We discuss these three types of gerontological scholars and implications for how these characteristics reveal ways that interdisciplinary training is shaping the purpose and scope of the field of gerontology.

### PARTNERING IN LONG-TERM CARE (LTC): A DEDICATED LEARNING UNIT FOR THE BSN STUDENT

K.F. Mullenbach, V. Burggraf, *Nursing, Radford University, Radford, Virginia*

This session will discuss the development of a partnership with academia and LTC in the development of Dedicated Learning Units (DLU). Such units have been popular in schools of nursing with students in their medical surgical clinical rotations, however none have been attempted in the US within the LTC environment. The purpose of the DLU is to provide an in-depth student immersion through a long-term care clinical experience with clinically adept/skilled gerontological nurse RN preceptors. The authors wll discuss their efforts in working with facilities to hire RNs, creation of site coordinators (graduate students), and the research initiatives to not only enhance clinical skills and improve resident quality of life but also provide the results of student pre and post test surveys. The unanticipated benefits for the univeristy, student and facility has led to an ‘adopt a student summer internship’ as well as future parterships in grants and programs. The DLU has created a positive environmnet in care of older adults for sstudetn nurses. The DLU and its positive results has the potential to ensure that the LTC workforce will be RNs in the future.

### EXTENDING OUR REACH: EFFECTIVE DISSEMINATION OF A GERIATRIC NURSING CLINICAL SIMULATION EDUCATION PROGRAM

V. Kowlowitz, K.R. Alden, C. Davenport, C. Durham, G.O. Mazzocco, M.H. Palmer, *School of Nursing, UNC at Chapel Hill, Chapel Hill, North Carolina*

Introduction: Successful dissemination of geriatric education programs will help meet the geriatric educational needs of nurses. Aim: To determine whether the Train the Trainer Model effectively disseminated a successful educational program to other sites. Methods: A continuing education (CE) offering that used clinical simulations, including human patient simulators (HPSs), to increase registered nurses’ (RNs) geriatric knowledge and skills was implemented at the UNC School of Nursing (SON) from 2004-2006. During 2006-2008, nurse educators at four North Carolina Area Health Education Centers (AHECs) received training to implement this workshop. The Train the Trainer Model included: how to use clinical simulations to teach nurses geriatric knowledge and skills; modifying case simulations; and accessing resource materials and simulation guides on an electronic course management system. Results: 172 nurses attended SON workshops and 176 attended AHEC workshops. Thirty-four counties were represented at the SON workshops and 33 at the AHEC workshops, with only seven counties represented at both. Mean age, ethnicity, and participants’ gender were comparable at SON and AHEC workshops. Although the pre-test and post-test scores on knowledge were significantly lower for participants at SON workshops (pretest: SON 60% versus AHEC 77%, $p = .00$; post-test: SON 75% versus AHEC 89%, $p = .00$), both groups showed significant improvement ($p = .00$) and the improvement between the groups was not significantly different. Participants rated their experience with clinical simulations very positively, with no differences among teaching sites. Conclusion: The train the trainer model successfully disseminated a geriatric nursing CE program for practicing RNs.

### PERCEIVED NEED FOR GERIATRIC TRAINING: DIFFERENCES IN TARGETED AUDIENCES

P. Sawyer[1], C. Ford[1], C. Ritchie[2,1], E. Kvale[2,1], P. Bosworth[1], A.G. Rothrock[1], *1. University of Alabama at Birmingham, Birmingham, Alabama, 2. Birmingham/Atlanta VA GRECC, Birmingham, Alabama*

To better plan for geriatric training, the UAB Geriatric Education Center developed and administered a needs assessment to three groups: members and affiliates of the Alabama Gerontological Society (AGS);

community physicians (CP); and nurses and social workers of the Alabama Department of Public Health (ADPH). Simple frequencies and t-tests for comparison of means from different samples were used to analyze results. There were 85 AGS respondents representing 14 disciplines; 25% of respondents were social workers. The ADPH respondents (N=202) included 61% social workers and 34% nurses. Thirty-three CP responded. Across all groups, topics most frequently selected for future geriatric training included depression/anxiety (65%); dementia/Alzheimer's disease (61%), falls/balance/mobility disorders (60%), diet and nutrition (57%), mild cognitive impairment (MCI) (47%). Highly ranked training needs were also identified for specific medical conditions including Arthritis/rheumotological disorders (49%) and diabetes (45%). There were significant differences between the three groups for perceived need. For example, the AGS (35%) did not rank falls/balance/mobility as highly as CP (73%) or ADPH (72%) (p<.001). MCI was a particular concern for the CP (64% vs. 38% and 39%; p=.012) as was pain management (61% vs. 33% and 14%; p<.001). Other topics with significant differences in interest by group included specific diseases, geriatric syndromes, psychological assessment and determining competency, end-of-life and ethical issues, physical fitness, substance abuse and polypharmacy, and community resources. Although there are common areas of perceived need for geriatric training, both professional setting and discipline-specific characteristics should be considered in the development of educational modules.

## SESSION 315 (SYMPOSIUM)

### HEALTHY AGING: WHAT CAN/DOES SCIENCE TELL US? WHAT (OR HOW) DOES THE PUBLIC WANT TO KNOW?

Chair: *G.H. DeFriese, Sheps Center for Health Services Research, University of North Carolina, Chapel Hill, North Carolina*
Discussant: *H.R. Moody, AARP, Washington, District of Columbia*

This symposium will address the challenge of amalgamating and translating the knowledge gained from scientific and applied research from multiple disciplines that can facilitate positive health improvement and the experience of healthy aging. Attendees at this symposium will (1) be able to describe some of the major research issues and themes being addressed in both the biology of aging and clinical geriatrics; and attendees will (2) better understand some of the anticipated issues involved in translating the extant science of aging and an understanding of the limits of contemporary knowledge in this field as part of an agenda for informing the public about these issues as AARP and AFAR jointly launch a new national communication initiative in this arena.

### WHAT ARE THE NEW DIRECTIONS AND CHALLENGES IN CLINICAL GERIATRICS?

W. Hall*, Medicine, University of Rochester, Rochester, New York*

This presentation will illustrate some of the most exciting new directions for clinical research in the field of aging and the potential for multidisciplinary approaches to common problems in this field. The presentation will also reflect upon the issues associated with efforts to translate basic science on the biology of aging for clinical application, as well as how lessons learned in clinical geriatrics can have influence in the way in which related basic research is conceptualized and carried out.

### WHAT DOES CURRENT SCIENCE IN THE BIOLOGY OF AGING TELL US ?

R. McCarter*, Penn State University, State College, Pennsylvania*

This presentation will summarize some of the most important issues and themes currently being addressed in the biology of aging, along with a description of the complexity of research programs related to several of the major strands of investigation in certain areas.

### LESSONS LEARNED ABOUT TRANSLATING RESULTS OF SCIENCE AND CLINICAL MEDICINE FOR PUBLIC DISSEMINATION AND USE

T. Prohaska*, Center for Research on Health and Aging, University of Illinois Chicago, Chicago, Illinois*

This presentation will offer a discussion informed by the social and behavioral science of public health of the important considerations in any attempt to effectively disseminate information of practical utility to the general public. The presentation will address required elements of the message critical to successful communication of advances in clinical, social behavioral health to the public. It will also provide strategies for successful translation and dissemination of advances in social and behavioral science into community based programs for improving the health of older adults.

## SESSION 320 (PAPER)

## HELP FOR CAREGIVERS

### HOW DID I SURVIVE A LONG-TIME FAMILY CAREGIVING CAREER? HANDLING CARE-RECIPIENT RESISTANCE

Y. Shirai, S.S. Koerner*, The University of Arizona, Tucson, Arizona*

In response to the well-documented negative impact of care-recipient problem behaviors on family caregivers (CGs), healthcare professionals have developed community CG support programs to help CGs manage and cope. However, regardless of whether CGs have participated in support programs, we are not certain about how individual CGs choose and/or develop their own survival strategies over a long-time caregiving career. By conducting semi-structured interviews with nineteen family caregivers reflecting on their long-time (mean, 9.4 years) caregiving experiences, this qualitative study documents CG experiences with an emphasis on a specific care-recipient behavior, care-recipient resistance during care provision (CR-resistance). The interviews captured individual CGs' (a) experiences of CR-resistance, (b) strategies for dealing with the CR-resistance, (c) strategies for coping with the emotional impact of CR-resistance, and (d) circumstances/background factors associated with their choices of survival strategies. Many of the participants (n=6) reported that they have attended a CG support group; the majority of those CGs viewed the support group as beneficial. However, our qualitative thematic analyses revealed that, over and beyond the professional support, certain circumstances/strategies seem to have a strong influence on CG resilience and survival in the face of long-time, persistent daily challenges such as CR-resistance: (1) CG attitude toward to the caregiving based on personal/family history (e.g., respect for care-recipient dignity); (2) CG's former work/personal experiences/skills that are applicable to the current caregiving situation; and (3) current social network and activities outside of caregiving. Implications for enhancing family CG support and professional CG training will be discussed.

### THE LEARNING NEEDS OF FAMILY CAREGIVERS WITH STROKE SURVIVORS DURING THE FIRST YEAR IN TAIWAN

C. Wu[1], L. Skemp[2]*, 1. Nursing, Meiho Institute of Technology, Kaohsiung County, Taiwan, 2. The Universtiy of Iowa, Iowa city, Iowa*

Family members' caregiving knowledge positively increases home care quality; however, the outcomes of educational interventions to increase caregiving knowledge, were inconsistently. This inconsistency may be because the educational content is often derived from health providers' views rather than from caregivers' views of their learning needs. The purpose of this descriptive qualitative study was to describe the learning needs of Taiwanese family caregivers who were caring for a family member who had experienced a severely debilitating stroke. Method: Seventeen family caregivers and 11 foreign care attendants who were caring for 16 stroke survivors were recruited from three hospitals in Southern Taiwan. Data collection included three formal interviews and one care activity observation. Findings: Family caregivers described learning needs presented before discharge, the first month after discharge, and when facing new care situations. Before discharge family caregivers focused on basic and immediately visible physical care problems. After discharge, they needed to learn how to deal with 15 caregiving challenges that arouse during the first month at home and when they faced new care situations. The most common challenges were diet, elimination and transportation. Caregivers also identified the need to manage their personal impact of being a caregiver and to deal with foreign care attendants' communication barriers and caregiving skills. All family caregivers were unprepared for the new care situations because of problematic discharge preparation and fragmented health care services after discharge. Recommendations: An organized and systemic discharge planning protocol and increasing in-home nursing, context specific caregiver education and rehabilitation services was recommended.

### MEMORY BANKING: A TOOL FOR CAREGIVING, QUALITY OF LIFE, AND LEGACY

A.F. Hosier[1], J.F. Watkins[2], F. Zanjani[2], *1. Family Studies, University of Kentucky, Lexington, Kentucky, 2. University of Kentucky-Graduate Center for Gerontology, Lexington, Kentucky*

Memory Banking is a five week interactive life history program designed to enhance empathic communications between a caregiver and care recipient through documenting and tracking personal life stories and health histories. This pilot study includes 60 caregiver dyads (120 participants) comprising one caregiver (18+ years) and one care recipient (65+). The cognitive competence of care recipients ranges from no cognitive impairment to clinically-diagnosed early stage dementia. By working with a caregiver to "bank" one's life story, care recipients are better able to guide healthcare decisions, person-centered options, and legacy. For caregivers, Memory Banking improves caregiver knowledge, including a greater understanding of behavior, mental health, and overall quality of care. This presentation highlights the process of Memory Banking, including the lesson plans and structure. In addition, the findings from the first group of participants (N=40) will be examined. The pre and post quantitative assessment battery and qualitative interviews measured participant perceptions of mental healthiness, cognitive ability, perceived stress, perceived support and quality of life.

### THE EFFECT OF WRITTEN EMOTIONAL EXPRESSION ON REDUCING STRESS IN CANCER FAMILY CAREGIVERS

H.K. Butcher, H.C. Bursch, Y. Perkhounkova, *College fo Nursing, University of Iowa, Iowa City, Iowa*

The purpose of this randomized clinical trial was to evaluate the effect of structured written emotional expression (SWEE) in decreasing the emotional and physiological burdens in 20 family caregivers (Mean age=63) of persons with cancer that were randomly assigned to an experimental or comparison group who wrote for 20 minutes on 6 alternating days. Experimental group family caregivers (N=11) wrote about their deepest thoughts and feelings about caring for their family member while those in the comparison group (N=9) wrote about non-emotional topics. Saliva cortisol was measured 4 times a day for two days at pretest, on the 4th and 5th and again at the 30th and 31st days after the first day of writing. A linear mixed model was used to analyze the data on all outcomes, a repeated measurement factor (session=pretest, posttest 1, and posttest 2) was modeled as a fixed effect. The model for cortisol included an additional repeated measurement factor, modeled as a fixed effect (time of saliva collection=awakening, 30 minutes after awaking, 4PM and bedtime). For Pennebaker Inventory of Limbic Languidness, a measure of physical symptoms of stress, treatment by session interaction was statistically significant (p=0.0193) and the difference between pre-test and second post-test was statistically significant for the SWEE group (p=0.0287), showing the decrease in average scores. Results for other outcome measures including saliva cortisol, caregiver burden (Caregiver Reaction Assessment Scale and Brief Assessment Scale for Caregivers showed trends in the hypothesized direction. Depression (CES-D), and Finding Meaning Through Caregiving Scale were not significant.

## SESSION 325 (POSTER)

## INTERVENTION TRIALS AND PROGRAMS

### UTILIZING CAREGIVER APPRAISALS IN THE DEVELOPMENT OF ADAPTIVE INTERVENTIONS

M. Barrineau[1], J. Lee[1], S.H. Zarit[1], E. Femia[1], C.J. Whitlatch[2], *1. Penn State University, University Park, Pennsylvania, 2. Benjamin Rose Margaret Blenkner Research Institute, Cleveland, Ohio*

Background: Assessments of family caregivers are widely used to identify stressors and aid in development of treatment plans. Caregivers' reactions to the assessment may effect subsequent engagement in treatment, but have never been systematically investigated. Methods: As part of an adaptive intervention, 32 family caregivers of people with dementia completed a comprehensive assessment including daily care challenges, degree of support and secondary stressors. Using an algorithm from pilot work, the research team constructed 7 stress scores and individualized recommendations for treatment components and dosage. Caregivers were asked the extent to which they agreed or disagreed with each score and treatment recommendation. After completion of treatment, caregivers evaluated the components and amount of treatment they received. Results: Caregivers showed high levels of agreement with the assessment results, reporting that 86% of stress scores were accurate, and agreeing with 97% of the recommended components of their treatment plan. Following completion of treatment, participants reported they were highly satisfied with the amount of each treatment component they received and rated components as helpful to them. Ratings of satisfaction were not related to number of sessions (dosage) that caregivers received ($r = .314$, $p > .05$). Conclusions: Results suggest that it may be possible to enhance a caregiver's engagement in an intervention program if s/he is encouraged to provide feedback and input about the recommended treatment options. The weak association between dosage and satisfaction suggests that getting the amount of treatment that participants believe they need is more important than how much treatment they receive.

### TREATMENT INTEGRITY OF AN ADAPTIVE INTERVENTION FOR CAREGIVERS USING MULTIPLE PERSPECTIVES

J. Lee[1], M. Barrineau[1], S.H. Zarit[1], E. Femia[1], C.J. Whitlatch[2], *1. Human Development and Family Studies, Penn State University, University Park, Pennsylvania, 2. Benjamin Rose Margaret Blenkner Research Institute, Cleveland, Ohio*

The Adaptive Caregiver Education and Support (ACES) intervention for family caregivers used an adaptive approach, assigning treatment modules and dosage depending on the initial risk profile of clients in three areas: behavior management, caregiver role strain and need for formal services. The present study investigates treatment integrity, specifically, were counselors able to implement the type and amount of treatment as planned and did they demonstrate competence in implementing treatment? Multiple perspectives (trained coders, counselors' ratings, caregivers' ratings) were used to assess treatment integrity. Codes were developed to rate interventions used in treatment sessions and the counselors' competence in implementing treatment. Four coders achieved satisfactory reliability (ICC=.84). Following each session counselors rated what treatments they implemented while caregivers (n=32) evaluated the sessions and their counselor's competence. Coders' ratings were correlated with counselors' ratings for the same sessions and were found to be highly related (r=.64). An ANOVA was performed to relate the amount of treatment actually given in each area across all sessions to the initial adaptive plan. Findings showed that counselors were able to differentiate in the treatment given to caregivers and implement the recommended amounts of each treatment. Finally, both coders and caregivers rated counselors high on competence, and the association between these ratings was high (r=.75). These findings demonstrate treatment fidelity of an adaptive intervention with caregivers. Type and amounts of treatment matched the individualized plans for caregivers and counselors were able to implement treatment in a highly competent manner.

## SMOKING CESSATION TREATMENT OUTCOMES AND MOTIVES FOR QUITTING DIFFER AMONG OLDER AND YOUNGER ADULTS

N. Sachs-Ericsson, N. Collins, M. Gerend, B. Schmidt, *Psychology, Florida State University, Tallahassee, Florida*

Background: Smokers seeking treatment may present with different motives for quitting depending on their age. Older adults tend to experience greater smoking-related health problems than younger adults, and thus, may be more motivated and successful in quitting. On the other hand, according to the "selection hypothesis of smoking," those younger adults who are successful in quitting may have lower rates of distress or health concerns. We examined differences in motivation to quit smoking and treatment outcomes by age and whether health concerns moderate the effect of age on treatment outcome. Method: We compared older and younger smokers enrolled in a 12 session cognitive-behavioral smoking cessation program (N=84) on the Reasons for Quitting (RFQ) Questionnaire at baseline and on smoking outcomes one month post treatment. Results: Motives for quitting smoking varied by age. Older smokers were motivated due to health and practical concerns, whereas younger smokers were motivated due to desire for self-control. Treatment outcomes also differed by age. Older smokers had better treatment outcomes despite heavier smoking at baseline. Importantly, treatment efficacy among older and younger smokers was modified by health concerns. Among participants who reported high levels of health concerns at baseline, increasing age was associated with lower levels of smoking urges or craving. Conclusions: Health concerns may motivate some subgroups of smokers to quit more so than others. Among those with health concerns, older smokers may respond more favorably to smoking cessation interventions than younger smokers. Smoking cessation programs should be tailored to smokers' motivations for quitting.

## COMPARING DIFFERENT MEMORY TRAINING MODELS: THE EAST AND WEST PERSPECTIVES

T. Kuo, A. Lai, S. Daly, W. Liu, *Central Taiwan University of Science and Technology, Taichung, Taiwan*

The purpose of this paper was to compare different memory training models around the world. In the past 10 years, many memory training programs have been developed, and the effects on maintaining mind alertness or slowing memory decline were evident. In recent years, memory training has become popular in Asia because the population is aging rapidly, and the awareness of keeping the brain working remains one of the top priorities among the elderly. The methodology of this paper was to search for different models in memory training. A total of 12 models from "East and West" perspectives was found. The rationales behind each of the 12 training models were compared based on how the training affected six areas: attention, language, logical process, demand execution, time orientation and recall. The results from comparing 12 different models showed that those from the Western perspective focused more on linguistic training and overall balance of wellness (e.g. nutrition, exercise and brain aerobics), while those from Asia employed more geometric symbols, numeric and herbal remedies. The reasons why such differences occurred could be due to literacy and culture, making the comparisons intriguing, and generating implications for future practice and research. This paper concludes by discussing practice implications where the 12 models could be used or disseminated when applying to multi-cultural audiences from different communities or countries.

## CONCEPT AND EVALUATION PROCEDURE OF AN INNOVATIVE COUNSELLING PROGRAM FOR VISUALLY IMPAIRED ELDERS

I. Himmelsbach[1], F. Oswald[1], F. Esch[2], S. Driebold[1], K. Metzler[2], *1. Working Group Interdisciplinary Ageing Research, Goethe University Frankfurt, Frankfurt, Germany, 2. Foundation for the Blind and Visually Impaired, Frankfurt, Germany*

Due to increased life expectancy the rate of visual impairment in later life will raise by 30% until 2030. Today about 30 million persons worldwide suffer from age related macular degeneration, the predominant cause of age-related visual impairment. However, their support in terms of interventions (including counselling) is still rather poor and unstructured. This presentation aims to introduce a new project which develops and evaluates an innovative counselling program for visually impaired elders. The program builds upon three main goals: (1) Understanding visual impairment in old age as a challenge for psychosocial counselling rather than a problem to be overcome by the use of technology; (2) Replacing existing segmented interventions by an integrative and comprehensive concept; (3) Combining the program with other programs for community dwelling elders in order to better serve the complex and changing individual needs as people age. To achieve these goals, a trained expert counselling and monitoring the client is the pivot point of the program. As part of the scientific monitoring, the evaluation covers a qualitative program development (month 1-18) in order to specify in detail the clients' needs and the outcomes (e.g. quality of life, psychological well-being and adaptation to vision loss), as well as a quantitative outcome evaluation (month 19-36) including a pre-post measurement design. Findings from a first set of 15 interviews are presented already reflecting the complex needs structure due to the parallelism of ageing and vision loss. Based on our findings, the counselling program is planned to be finally implemented in the healthcare system.

## AN EXAMINATION OF DOSE EFFECTS IN A CLINICAL INTERVENTION TRIAL FOR CAREGIVERS

S. Clancy Dollinger, K. Chwalisz, K. Hand, E. Hlaing, S.L. Parks, *Psychology, Southern Illinois University, Carbondale, Illinois*

The Southern Illinois Rural Caregiver Telehealth Intervention Trial (R01NR008280-01) was a multi-component telehealth intervention designed to specifically meet the needs of informal caregivers in a rural area. Participants were randomly assigned to either an 8-week treatment condition or helpline treatment condition. Physical/mental health and psychosocial functioning were obtained at baseline, post intervention and 6 month follow-up. The current study examined the nature of therapeutic change related to dosage for caregivers participating in the intervention. The relations between time spent on each intervention component (Managing Feelings, Knowledge, Problem Solving, and Social Support) and client outcome at 6 months based on change scores on the Social Provisions Scale, OQ45.2, Social Problem Solving Inventory Revised, SF-36 and the Perceived stress scale were examined in a high dosage group (≥ 350 minutes) vs. a low dosage group (≤ 50 minutes). Total therapy minutes accounted for 21.3% of the variance on the Perceived Stress Scale. Time spent on specific components was related to different outcome measures. Minutes spent on problem solving ability in the high dosage group was positively related to scores on the Rational Problem Solving scale of the Social Problem Solving Inventory – Revised. Scores based on the Nurturance subscale of the Social Provisions Scale were positively related to minutes spent on the Managing Feelings component of the intervention in the high dosage group. Dosage by condition was significant for the Guidance subscale of the Social Provisions Scale. The implications of dose effects for tailored caregiver interventions are considered.

### CLINICAL PRACTICE AND RESEARCH TRANSLATION: TRYING NEW THINGS AND LEARNING TO DANCE

T. Wharton[1], L. Burgio[2], G. Harris[3], B. Schmid[4,3], R.S. Allen[3], *1. School of Social Work, University of Alabama, Tuscaloosa, Alabama, 2. University of Michigan, Ann Arbor, Michigan, 3. University of Alabama - Dept of Psychology, Tuscaloosa, Alabama, 4. VA Medical Center, Tuscaloosa, Alabama*

Making the shift from research to practice is anything but straightforward. Even after solid partnerships are in place and intervention programs are underway, keeping clinical practice and research in sync can be a challenge. Clinical practice decision-making and research studies are not necessarily framed from the same perspective, and decisions made to meet the goals of one set of stakeholders can present unexpected outcomes to the other. Even when research team members come from clinical backgrounds, assumptions are sometimes made about how things will fit together, and when these assumptions are challenged, researchers are required to join their partners in a dance of learning to adapt our needs and expectations to the flexibilities of clinical reality. Strong partnerships, flexible expectations, and an open mind to new discoveries can make translational projects a rich and rewarding endeavor, even with the sometimes unexpected tango. This poster uses the example of translation from RCT studies to the Resources for Enhancing Alzheimer's Caregiver Health- Offering Useful Treatments (REACH-OUT) pilot projects to explore lessons learned at the intersections of research and practice.

### PROFILING USERS AND NON-USERS OF SENIOR SERVICES

E.E. MaloneBeach, R.A. Heuberger, *Human Development and Family Studies, Central Michigan University, Mount Pleasant, Michigan*

Even as the number of older adults has increased, Title III service use has decreased in recent years. The reasons for this trend are unclear. The purpose of this study was to examine four categories of influence on service use: demographic, physical well-being and health, psychological, and social well-being. Rural older adults aged 60 – 103 (N=1065) were interviewed to profile those who use services. Results indicate that service users (N = 177) were older, more infirm, living alone and less able to perform Activities of Daily Living (ADL) and other physical activities than people who had not yet begun to use services. The non-service user group (N = 888) was not attracted to the current array of services or did not consider service use since they were doing well. Alternately, the trend toward a decrease in service use may reflect a compression of morbidity; demand for services will again increase when boomers age past their disability-free years. The non-service user group, however, also included a subset of elders who were infirm, malnourished, less active, and unable to perform all of the ADLs. These individuals appeared to be "graduates" of services who had not successfully transitioned to appropriate inhome services as their impairments increased. Most of these would benefit from involvement in Title III programming and should be targeted for service provision that is adapted to meet their higher levels of need. The description of this subset of nonusers may be useful to service providers and policy planners.

## SESSION 330 (POSTER)

## MANAGING CHRONIC ILLNESS

### AN EXAMINATION OF DAILY STRESS AND COPING WITH ARTHRITIS AMONG BLACK AND WHITE WOMEN

C.A. Mingo[1], M. Lunsman[1], J.M. McIlvane[1], E. Brown[2], K.S. Birditt[3], *1. School of Aging Studies, University of South Florida, Tampa, Florida, 2. University of Connecticut, Storrs, Connecticut, 3. University of Michigan, Ann Arbor, Michigan*

This study took an in-depth view of race and SES differences in daily stress (e.g., interpersonal, home, health) and coping with arthritis (e.g., relaxation, spiritual). Participants were Black (N=21) and White (N=20) women aged 48-89 (mean = 68.7). Stress and coping were assessed using 10 daily telephone interviews. The most common stressors for both Blacks and Whites, as assessed by percent of study days reported, were interpersonal (Blacks-25% of days, Whites-17% of days), network (Blacks-15% of days, Whites-13% of days), home (Blacks-4% of days, Whites-10% of days), and health (Blacks-4% of days, Whites-6% of days). A series of 2X2 (race X education) ANOVA's for stress and coping revealed Black women were more likely to use relaxation, try to see the pain in a different light, express emotions, and seek spiritual comfort compared to White women. Women with higher education had more network stress and were less likely to seek emotional support. Two race x education interactions showed that White women with lower education experienced more home stress, F (1,37) = 4.11, p= .05, and more health stress, F (1, 37) = 3.77, p= .06, while Black women with lower education experienced less home and health stress, although the effect for health stress was marginally significant. Results indicate that studies of the chronic illness experience should go beyond examining only illness-related stressors and consider the broader context in which people live. While this is an exploratory analysis, examining stress and coping among Blacks and Whites in "real-time" is a major strength.

### ACTIVITY EXPENDITURE AND ACTIVITY SELF-REGULATION IN THE CONTEXT OF ARTHRITIS SEVERITY AND HEALTH

J. Son[1], M. Janke[2], J.J. Jones[1], *1. University of Illinois at Urbana-Champaign, Champaign, Illinois, 2. University of South Florida, Tampa, Florida*

Arthritis is one of the most prevalent chronic health conditions in mid to late life. Participation in leisure activities is one way adults with arthritis can maintain physical health and psychological well-being. Participants completed a questionnaire on-site at subsidized apartment complexes, independent living centers, and recreation facilities. Our sample included 178 adults with arthritis aged 51 to 95 (M = 75), predominantly female (84%), White (91%), with approximately 28% characterized as resource-poor. The questionnaire included: leisure activity expenditure using estimated metabolic equivalents (METs); activity self-regulation using Baltes, Baltes, Freund, and Lang's (1999) 24-item selective optimization with compensation scale, modified in reference to leisure activities; health measured using the AIMS, an arthritis-specific health scale including activities of daily living (ADLs), social activities, pain, and depression; and arthritis severity. We examined activity expenditure and activity self-regulation as mediators of arthritis severity and health as well as activity expenditure as a mediator of activity self-regulation and health. We controlled for age, gender, race and resources in the analyses. Variables in the final reduced model explained 41% of the variance in health, with activity expenditure partially explaining the relationship between self-regulation and health. Activity self-regulation was positively related to activity expenditure which, in turn, was associated with better health. However, self-regulation was also directly related to poorer health. We provide a discussion of the possible reasons for these countervailing effects, in light of the process of selective optimization with compensation and with implications for arthritis self-management.

### USE OF COMPLEMENTARY AND ALTERNATIVE MEDICINE FOR MUSCULOSKELETAL AND CONNECTIVE TISSUE PROBLEMS

S.B. Laditka, J.N. Laditka, E.M. Tait, M.M. Tsulukidze, *Public Health Sciences, University of North Carolina at Charlotte, Charlotte, North Carolina*

Half of U.S. adults ages 50+ use complementary and alternative medicine (CAM). Little is known about reasons for CAM use. We examined reasons with data from the 2007 National Health Interview Survey and its CAM supplement for adults. Analyses, including logistic regression accounted for the survey design and were weighted for national representativeness. Outcome variables in separate logistic analyses included several reasons respondents gave for using CAM. Results identify the principal health conditions associated with each reason, adjusted for other factors. Controls included age, race/ethnicity, gender, education, marital status, income, health insurance, comorbidities, self-reported health needs, body mass index, health behaviors, and region. Among adults 50+ (n=10,104), 35% used CAM for musculoskeletal and connective tissue problems, including arthritis/rheumatism, back and neck problems, and other bone or joint problems; these conditions are often accompanied by chronic pain that may not respond well to conventional therapies. In adjusted results, those with musculoskeletal and connective tissue problems had higher odds of CAM use because: a provider recommended it (odds ratio 1.65, 95% confidence interval 1.47-1.86), family or friends recommended it (1.44, 1.28-1.61), traditional medicine did not help (2.63, 2.07-3.35), and traditional medicine was too expensive (1.77, 1.38-2.28). Health providers often recommend CAM to treat musculoskeletal and connective tissue problems. A substantial number of older adults with musculoskeletal and connective tissue problems use CAM because medical treatments do not help or are too expensive. CAM can interact with conventional therapies; providers should ask patients with these conditions about their CAM use.

## PILOT STUDY OF OLDER ADULTS LIVED EXPERIENCE OF TRANSITIONING FROM HOSPITAL TO HOME

S. Buckner, J.S. Wilson, *University of Oklahoma College of Nursing, Oklahoma City, Oklahoma*

Transitioning from the hospital to the home is a significant problem since many older adults (defined as those 65 years and older) return to the hospital once they are discharged, often due to unmet, complex healthcare needs. In one year alone, these unplanned hospitalizations resulted in over $17 billion dollars in costs to Medicare. Research in this area has focused on primarily three types of outcome measures: healthcare resource use (e.g., length of stay during hospitalization), demographic characteristics (e.g., age or gender), and physical factors (e.g., change in sensory or mobility) that might impact transitioning. Few studies included the client's perspective about this transitional time period. **Purpose:** This descriptive, qualitative study was designed to explore the lived experiences of older adults transitioning from the hospital to the home. This study served as a pilot to inform future doctoral work in this area. **Methods:** Using a phenomenological approach, participants included four urban older adults living in the Midwest who had been hospitalized in the previous year. The main research question was, "What are lived experiences of older adults (aged 65-90) when transitioning from the hospital to the home environment?" Data gathered from audio-recorded interviews were analyzed for significant statements and themes. **Findings:** Qualitative findings revealed challenges in self-management once discharged from the hospital to the home which included managing their medical regimen. These findings may help clinicians understand how an older adult perceives transitioning which may, in turn, help improve this period of time for older adults.

## SYSTEMATIC REVIEW OF SELF-MANAGEMENT OF CHRONIC ILLNESS INTERVENTIONS FOR OLDER ADULTS: A FOCUS ON GERONTOLOGICAL SOCIAL WORK PRACTICE

A. Roberts, K.B. Adams, *Case Western Reserve University, Cleveland, Ohio*

Self-management programs aim to reduce the rate of functional decline and enhance the health and wellness of older people through education and social support. Social work values and competencies are closely aligned with health promotion models which depend upon comprehensive self-care, self-efficacy, and empowerment strategies. The following research questions were addressed: To what extent are social workers involved in self-management programs for chronic illness? What roles did social workers play in self-management interventions? Finally, what is the efficacy and effectiveness of interventions that included social workers? A comprehensive literature search was performed to identify self-management with chronic illness interventions that met the following criteria: the average age of the participants with one or more chronic illness was 60 or older, outcome measures were reported, and the intervention was implemented by social workers. Methodological quality was assessed by standard criteria adopted by the American Psychological Association. Using this inclusion criteria with eight electronic databases, we found only three group and six individual studies published through February 2010. Studies varied in scope, type of chronic illness, target population, research methodology, sample size, and social worker roles. All described social workers functioning as part of an interdisciplinary team. The most frequent roles were: counselor, educator, group facilitator, and resource broker. Major outcomes included a reduction of depression and improved self-management behaviors. Three randomized clinical trials were evaluated as "possibly efficacious." Future research should replicate findings, use longitudinal designs and standard valid and reliable outcome measures, compare intervention intensities, and explore causal factors.

## PREDICTORS OF SELF-CARE BEHAVIORS AMONG TYPE 2 DIABETICS: RESULTS FROM A LOGISTIC REGRESSION TREE ANALYSIS

T. Yamashita, C.S. Kart, D.A. Noe*, Miami University, Oxford, Ohio*

Diabetes mellitus (DM) is a growing public health problem in the U.S. and puts individuals of all ages at risk for catastrophic consequences and death. Such consequences may be mitigated by effective clinical and self-management. Whereas some medical consensus exists about the behaviors necessary for effective DM self-management, less is understood about the demographic and health-related characteristics of those adults with the disease who practice the recommended self-care regimens. Using logistic regression tree methods, this study examines the CDC's 2005 BRFSS data to profile the characteristics of 21,305 individuals with type 2 DM (Mean age = 62.3 years, SD = 12.8) for three critical self-care behaviors: frequency of blood glucose monitoring, checking feet and Hemoglobin A1c test. The logistic regression tree method partitions data into meaningful subgroups with similar characteristics (e.g., female patients, aged 75+) and fits a different logistic regression to each subgroup. Unlike traditional methods, this analysis detects specific combinations of characteristics and a corresponding chance of practicing the recommended self-care behaviors. Results indicate that for blood glucose monitoring, individuals who have participated in a formal DM management education program and managed DM for greater than 7 years were most likely to meet the recommended self-care regimen. Those who have participated in a formal DM management education program and consumed more fruits/vegetables in their regular diet were most likely to practice regular feet checking. Finally, the strength of the tree-based logistic regression method as well as possible implications for future DM intervention and education programs will be discussed.

## ETHNIC/RACIAL DIFFERENCES IN DIABETIC CONTROL FOR OLDER ADULTS: IMPACT OF IMPORTANCE OF RELIGION

C. Guarnaccia*, Department of Psychology, University of North Texas, Denton, Texas*

Health and Retirement Study (HRS) 2003 Mail Survey on Diabetes data for 1042 diabetic individuals was analyzed to examine the relationship between glycated hemoglobin (HbA1c) level (a 60 to 90 day measure of diabetic control), and self-rated Importance of Religion and religious participation. These religiosity measures were taken from the 2002 and 2004 core interviews which bordered the 2003 off core-year Diabetes Survey. In these analyses, self-rated Importance of Religion and participation was extremely stable between the 2002 and 2004 core interviews, allowing these ratings to be extended to and used in conjunction with the 2003 survey data. In an ANCOVA analysis Importance of Religion as the covariate was found to statistically reduce the large racial, health disparity, preexisting difference between African American and non-Hispanic Caucasian older diabetic individuals (F=53.48, p<.001). The Hispanic diabetic individuals were not found to be different from the non-Hispanic Caucasian individuals. The impact of the self-rated Importance of Religion covariate reduced these health disparities (F=3.85, p<.05). These results suggest that greater religious affiliation has additional protective benefits for African American older adults. The examination of diabetes as a chronic illness requiring extensive self-management activity compared to other chronic illnesses, highlights such religious affiliation benefits. This Importance of Religion and religious participation benefit was only found for the diabetic individuals who did not require insulin therapy. These individuals with Type I diabetes and more severe Type II diabetes did not show the benefit of lower HbA1c levels with greater involvement in religious focus and participation.

## SOCIAL SUPPORT: PATHWAY TO SUCCESSFUL SELF-MANAGEMENT AMONG MID- TO LATE-LIFE AFRICAN AMERICAN WOMEN

I.S. Harvey, *Kinesology and Community Health, University of Illinois Urbana Champaign, Champaign, Illinois*

Social support is a complex multidimensional construct, and research indicates that social support can be beneficial to the recipients. However, research also suggests that without an optimal match, social support can also be less satisfying to recipients. Because social support involves both a provider and a recipient, the possibility of mismatch between the intention of the support giver and perception of the support receiver is likely to occur. The purpose of this study is to examine the relationship between support providers and those receiving support among mid- to late-life African American women with chronic conditions. In-depth, semi-structured interviews were conducted with 30 women to discuss what type of social support they received from their primary relationship [i.e., daughter (N=15) or best friend (N=15)] in managing their chronic conditions. Interviews were audio-taped, transcribed verbatim, and then conducted using a dyadic narrative analysis. Prior to each discussion, a quantitative questionnaire assessed the various type of social support received and type of self-management practices performed. The quantitative study analyzed social support as the mixed predictor variable, types of relationships as the between-dyads variable, and self-management practices as the outcome variable. Results indicated that age of the recipient, number of chronic conditions, and friends' social support were important predictors of the type of self-management practices. In addition, narrative analysis identified the different patterns of social support among relationships. Daughters provided more instrumental support while friends provided more emotional support. The results have implications in designing specific support programs among relationships for African American women with chronic conditions.

## SOCIAL RELATIONSHIPS, SELF-EFFICACY AND DIET-RELATED OUTCOMES IN ADULTS LIVING WITH DIABETES

L.A. Wray[1], M. Franks[2], C. Chiu[1], C.L. LaCoe[1], *1. Biobehavioral Health, Penn State University, University Park, Pennsylvania, 2. Purdue University, West Lafayette, Indiana*

Social relationships (and particularly marriage) and self-efficacy have long been documented as important predictors of enhanced health outcomes, including those related to diabetes management. Using data from the 2002 and 2004 core interviews of the nationally representative Health and Retirement Study (HRS) and the 2003 supplemental diabetes-specific mail survey for 1,481 adults living with diabetes, and structural equation modeling, this study examined how diet-related social support and self-efficacy influence adherence to diet-related management recommendations and, in turn, to HbA1c levels (as a measure of glycemic control), and if those relationships differ by marital status. Bivariate analyses showed that married/partnered adults significantly differed from their unmarried counterparts on diet support, diet efficacy, and diet behavior but not on HbA1c. Results of our structural equation model analyses indicated that: (1) greater diabetes support predicted better diet adherence, and more strongly in married or partnered adults than in unmarried adults; (2) higher levels of self-efficacy predicted greater diet adherence similarly in both married and unmarried adults; and (3) self-efficacy and diet adherence explained 10.6% of the effect of diabetes support on HbA1c levels. These results suggest that social support and self-efficacy play important roles in the diabetes management in adults with diabetes, and that these roles may differ by marital status. Further investigation is needed to clarify how marriage influences health outcomes in adults living with diabetes.

## HOW CRITICAL MEDICAL EVENTS PROVIDE OPPORTUNITIES FOR SOCIAL WORK INTERVENTION FOR THE OLDER ADULT PATIENT

D.K. Griffith, *Geriatrics, University of Michigan Health System, Ann Arbor, Michigan*

Critical medical events of the older adult patient provide excellent opportunities for interventions by medical social workers. Dr. Caroline Blaum, the Associate Chief of the University of Michigan Division of Geriatric Medicine, as well as a Research Professor in the University of Michigan Institute of Gerontology, developed the Transitional Care Clinic (TCC) which offers an outpatient alternative to exhausting emergency room visits and debilitating inpatient hospitalizations for older adult patients. Dr. Blaum chose a full time social worker to be part of her TCC medical team. Social work completes a psycho-social assessment. Unmet needs are identified. Social work helps the patient access area resources that can provide needed services. Educating patient and caregivers about disease progression and how it affects daily functioning provides opportunities for social work to discuss long term planning and advanced directives with the patient. Helping the patient determine how to handle future exacerbations of the chronic illness, and facing his/her overall functional decline, can help guide the patient toward Palliative Care and Hospice when needed. Providing encouragement and emotional support for caregivers helps them be more vigilant and observant. They are then more likely to call TCC and thus avoid costly ED visits and hospital stays. During the first quarter, 69 patients were seen in the TCC; compared to 158 patients seen last quarter. The success of the TCC in Geriatrics helped establish similar clinics in Ambulatory Psychiatry, Outpatient General Medicine, and in one of the Family Practice clinics All Geriatrics Center social workers have adopted the interventions of the TCC social worker when meeting with patients who have had recent hospital stays. Providing a link between inpatient and outpatient medical care has been the primary focus of the social work role in the Transitional Care Clinics at the Geriatrics Center and over the last 4 years has become the Model of Care for primary care patients.

## UNDERSTANDING HEALTHCARE MANAGEMENT TASK DIFFICULTY AMONG DIABETIC MULTIMORBID OLDER ADULTS

T.B. Hughes[1,3], E.R. Giovannetti[1,3], L. Reider[1], J. Wolff[1,2,3], C. Weiss[1,2], Q. Xue[1,3], C. Boult[1,2], C. Boyd[1,3], *1. Johns Hopkins University, Baltimore, Maryland, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, 3. Center on Aging and Health, Johns Hopkins Medical Institutions, Baltimore, Maryland*

Diabetes mellitus is common in older adults, and often co-exists with other chronic conditions. The application of disease-specific guidelines to older adults with diabetes and multimorbidity may result in complex regimens that impose significant "treatment burden." Methods: To explore the concept of treatment burden we examined self-reported difficulty in managing 8 health care tasks and the association between this difficulty and quality of life and quality of care in a cross-sectional secondary data analysis of older adults with diabetes (n=425). We generated and validated a scale (0-16) of self-reported difficulty with health care management tasks from 8 questions. Patient-reported quality of care (Patient Assessment of Chronic Illness Care) and mental and physical health (SF-36 scales) were examined; and associations with the difficulty scale were tested using regression analyses. Results: Number of chronic diseases was associated with increased treatment difficulty ($p<.05$). A statistically significant stepwise association was found between increasing level of difficulty with health care tasks and lower mean score on the SF-36 physical health scale (no difficulty (38.4), low difficulty (38.5), moderate difficulty (35.0), and high difficulty (32.2), Cuzick's test for trend $p<0.05$), mental health scale (no difficulty (51.5), some difficulty (47.6), moderate difficulty(46.2), and high difficulty (41.3), Cuzick's test for trend, $p<0.05$), and patient-reported quality of care (Cuzick's test for trend $p < 0.05$). Conclusion: Difficulty with health care tasks may have implications for quality of life and quality of care. Future research will investigate the importance of treatment burden for clinical decision-making.

### OBJECTIVE VS. SUBJECTIVE INDICATORS OF ADEQUATE EXERCISE AMONG HRS RESPONDENTS WITH DIABETES

M. Janevic, C.M. Connell, N. Janz, N. Clark, *Center for Managing Chronic Disease, University of Michigan, Ann Arbor, Michigan*

Regular exercise is one of the cornerstones of diabetes self-care. The American Diabetes Association (ADA) recommends at least 150 minutes/week of moderate-intensity physical activity and/or 90 minutes/week of vigorous exercise. However, the extent to which these guidelines line up with older adults' own assessments of the adequacy of their physical activity is not known. Data from the national Health and Retirement Study's mailed 2003 Diabetes Supplement (N=1803 individuals with diabetes, aged 51- 96 years) was used to calculate the proportion of individuals who reported that they exercised "the right amount" but did not meet ADA guidelines according to a summary variable of minutes/week spent in physical activity (including both household tasks and leisure). This analysis was repeated within gender, race, and education subgroups. Overall, 65% (n=1161) of respondents thought they exercised too little; 33% (n=593) the right amount; and 2% (n=30) too much. Among those who thought they exercised sufficiently, 46% (n=276) did not meet physical activity guidelines. This percentage was higher among women (55%) than men (39%); among Black (65%) compared to White (41%) and Hispanic (49%) respondents; and among respondents without a high school diploma (63%) compared to those with a diploma (44%) or at least some college (24%). Among people with diabetes, women, African Americans, and individuals with less formal education are at highest risk of erroneously believing that they get enough exercise. Efforts to effectively convey the actual activity guidelines to these groups are needed, along with strategies to reduce their barriers to exercise.

### MEDICATION MANAGEMENT, ADHERENCE AND HEALTHCARE UTILIZATION IN VISUALLY IMPAIRED AND NORMALLY SIGHTED VETERANS

K. Echt[1,2], M.D. Williams[3,1], L.P. Nadel[1], C.L. Jasien[4], A.B. Burridge[5], T. Munir[1], V. Phillips[6], W.R. De l'Aune[1], *1. Atlanta VA Rehabilitation Research & Development Center of Excellence for Aging Veterans with Vision Loss, Decatur, Georgia, 2. Emory University School of Medicine, Geriatrics & Gerontology, Atlanta, Georgia, 3. VA Blind Rehabilitation Service National Program Office, Decatur, Georgia, 4. Atlanta VA Health Services Research & Development, Decatur, Georgia, 5. University of Houston, Houston, Texas, 6. Emory University Rollins School of Public Health, Atlanta, Georgia*

Visual impairment is more prevalent in aging and may negatively impact medication management and adherence. This study investigated medication management, adherence and healthcare utilization in visually impaired and matched normally sighted individuals alongside vision, cognition and psychosocial predictors. Community-dwelling veterans (n=180) aged 34-94 years (M=68, SD=15) participated. These 90 visually impaired (corrected acuity≥20/60) and 90 normally sighted (corrected acuity≤20/40) participants completed measures of vision (i.e., acuity, fields), cognition (i.e., working memory, prospective memory, verbal ability) and psychosocial factors (i.e., patient activation, self-efficacy). Indicators of medication management and adherence included: self-reported adherence (Morisky), capacity with familiar (Drug Regimen Unassisted Grading Scale) and novel regimens (Hopkins Medication Scale), and calculated medication refill gaps using electronic medical record pharmacy data (Cumulative Medication Gap). Healthcare utilization was also determined from the medical record for the prior year. Current findings indicate that visually-impaired participants self-reported greater adherence than normally-sighted [$t(178)=-3.02$; $p<.01$], however differences in capacity (91% versus 94%) and refill gaps (16% versus 13%) were subtler, respectively. Cognition was most strongly correlated with the management and adherence indicators (r's=.30-.50), particularly with novel regimen capacity. Visually impaired participants utilized less healthcare in the prior year than the normally sighted (M cost=$12,000 versus $18,000; $p<.01$). Higher average daily number of medications for the prior year ($r=.36$) and worse self-reported adherence ($r=.25$) were significantly related to healthcare utilization. The findings characterize the differential contribution of vision, cognition and psychosocial factors on indicators of medication management and adherence and on healthcare utilization in persons with and without visual impairment.

## SESSION 335 (SYMPOSIUM)

### MEN'S EXPERIENCES WITH CANCERS

Chair: *E.H. Thompson, Sociology & Anthropology, College of the Holy Cross, Worcester, Massachusetts*

Co-Chair: *K. Davidson, University of Surrey, Surrey, United Kingdom*

A cancer diagnosis triggers a range of powerful emotions, from stoic acceptance to despondency to anger to fear. Men who experience cancer will be challenged as men. Their cancer is a biographical disruption. The man's pre-cancer sense of who he is is no longer the reference point. The guiding question for this symposium was 'What are men's experiences as men after their cancer diagnosis and treatment?' Men with cancer are compelled to (re)negotiate a self that is pinched between their now vulnerable body and the meaning of being a man in American society. The four studies presented in this symposium examine how men with prostate and breast cancers experience the liminal recognition they now embody marginalized, subordinate forms of masculinity. Major themes that emerged include the similarities across cancers in both negative impacts—a sense of needing to reconstruct masculine identities, lesser quality of life in large part based in sexual functioning—and the positive effects of re-establishing masculinities through new venues.

### HEALTH-RELATED QUALITY OF LIFE FOR GAY/BISEXUAL MEN WITH PROSTATE CANCER

D.W. Coon[1], S.L. Hart[2], M.A. Kowalkowski[3], D. Latini[3,4], *1. Arizona State University, Phoenix, Arizona, 2. Ryerson University, Toronto, Ontario, Canada, 3. Baylor College of Medicine, Houston, Texas, 4. Michael E. DeBakey VA Medical Center, Houston, Texas*

Over 5,000 gay/bisexual (GB) men are diagnosed with prostate cancer (PCa)annually and at least 50,000 are undergoing or have completed PCa treatment, but their quality of life (QOL) is unknown. Seventy-six GB men diagnosed with PCa in the prior three years completed an online survey that included validated general-(SF-36 v 1.0) and disease-specific (Expanded Prostate Cancer Index) QOL measures. We compared participants to published data from large community samples. Survey participants reported significantly lower urinary, bowel, and hormonal functioning, SF-36 Mental Composite Scores, and higher fear of recurrence than published data (all p < .001). No differences were seen in sexual functioning or bother. Most participants had primary partners (65%) but 29% said their partners were not included in healthcare decision-making. GB men treated for PCa report substantially lower QOL than other PCa survivors, indicating they may be a group with greater need for supportive interventions.

### BEING A PROSTATE CANCER SURVIVOR: STORIES OF CHANGES AND CHALLENGES RELATED TO MASCULINITY

T. Blank, *Human Development and Family Studies, University of Connecticut, Storrs, Connecticut*

Many men treated for prostate cancer feel their lives have taken a new trajectory. A significant aspect involves changes in how they feel about themselves as men; these reconstructions may begin at diagnosis and be intensified by treatment-caused erectile dysfunction and alterations in long-term relationships. This paper incorporates three data sources to explore the lived experience of a new trajectory: open-ended answers about changes and challenges of prostate cancer by 509 men diagnosed 1-8 years previously, interviews with 11 men diagnosed six months to three years earlier addressing the narrative of the man's prostate cancer experience, and personal experiences of the presenter. Major themes that emerged include both negative impacts—a sense of loss of feelings of masculinity, in large part based in sexual functioning—and positive ones of re-thinking and re-establishing views of masculinity and identity by accommodating to the changed physical and psychological context.

### DYADIC SUPPORT AFTER RADICAL PROSTATECTOMY: "MEN TELLING IT LIKE IT IS"

B.A. Weber, B. Roberts, B.J. Lutz, *University of Florida, Gainesville, Florida*

Men surviving prostate cancer treatment are reluctant to take part in support groups despite the benefit supports groups are known to have for patients with other types of cancer. Thus, a program of peer-to-peer support (dyadic) was developed with the hypothesis that it would be more appealing to men than large support groups. Results were favorable, but left several unanswered questions for understanding the efficacy of dyads. This secondary analysis used iterative thematic analysis to assess the dyadic discussions. Conversation was unstructured but discussion predominantly related to coping with the day-to-day consequences of radical prostatectomy included urinary incontinence and erectile dysfunction. Two domains were identified (friendship and information seekers) with the following overlapping themes (1) getting to know you, (2) somatic complaints, (3) hope, and (4) new perspectives on life. Results from this study will inform health care providers of the needs and concerns men have following radical prostatectomy.

### "YOU GOTTA BE KIDDING ME!": MALE BREAST CANCER

E.H. Thompson, A.S. Leichthammer, *Sociology & Anthropology, College of the Holy Cross, Worcester, Massachusetts*

The notion of breast cancer as a woman's disease parallels prostate cancer as an 'old man's' disease. But these gendered conceptions contribute to unawareness that breast cancer in men is possible, leads to later detection and higher mortality rates. Using the constant comparative method and coding paradigm of grounded research, interview data with 17 men give voice to the embodied experiences of men with breast cancer. Men revealed shock, not embarrassment with diagnosis and post-surgical hormonal therapy. Their 'identity talk' details strategies of stoic management, presenting the illness experience as 'just another hill to climb'. Findings also challenge the question that men would sense emasculation. Some divulged initial feelings of the indignity of having breast cancer, but most did the opposite of hide in shame; they sought to publicize their experience. Feelings of being medical, but not social oddities, they resisted marginalization.

## SESSION 340 (PAPER)

## OLDER WORKERS: INITIATIVE AND FITNESS

### WORK MOTIVATION AND REGULATORY BEHAVIORS OF OLDER MANAGERIAL EMPLOYEES

D. Yeung[1], H. Fung[2], D. Chan[2], *1. City University of Hong Kong, Hong Kong, Hong Kong, 2. The Chinese University of Hong Kong, Hong Kong, Hong Kong*

There is an increasing interest in investigating the impacts of developmental changes on job performance of middle-aged employees. This project aimed at comparing work motivation and self-regulatory behaviors between younger and older working adults. Study 1 consisted of 295 Chinese managerial employees aged between 23 and 60 years. Participants completed a set of questionnaires on work motives, regulatory strategies and job performance. Study 2 was an experience sampling study to assess on-the-job work motives and regulatory behaviors of 100 managerial employees. Participants were asked to carry a handheld computer for two weeks and their momentary responses at work were recorded. Preliminary analysis of Study 1 demonstrated that older employees reported a higher level of intrinsic motivation {$t(293) = -3.11$, $p <.01$} but less internally imposed motivation {$t(293) = 2.24$, $p <.05$} than did younger employees. Age differences were also found in the use of regulatory strategies: As compared with younger workers, older workers reported greater use of elective selection ($t(293) = -2.26$, $p < .05$) but less employment of compensation ($t(293) = 1.99$, $p < .05$). Multiple regression analysis demonstrated that the positive relationship between intrinsic motivation and job performance was stronger for older employees (age by intrinsic motivation interaction, $\beta = 1.479$, $p <.001$). Result findings of this project would provide important implications to employers for understanding work motives and adjustment of older employees.

### ENTREPRENEURSHIP AT THE OLDER AGES

J.C. Scott, J. Diebold, *Public Policy, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

Despite the current economic downturn, some older Americans are engaging in new business ventures. Bridging the literatures on entrepreneurship and the aging workforce, the research question for this project is what factors are associated with entrepreneurship at the older ages? After attending this session, participants will be able to identify possible determinants of, and discuss methodological issues related to, entrepreneurship in old age. Using all 9 waves of the Health and Retirement Study, we model the factors contributing to entrepreneurship for those 50 and older. We define three types of entrepreneurship: self-reported self-employment status, self-employment combined with supervisory responsibilities, and self-employment in so-called 'knowledge' occupations. Key explanatory variables include risk perceptions and perceptions of time horizons. Preliminary results suggest several factors that facilitate entrepreneurship. We find that more openness to risk is associated with entrepreneurship and self-employment. Moreover, resources in the form of household wealth and education are a significant if unsurprising contributors to entrepreneurship. Interestingly, those respondents who value work in and of itself are much more likely to engage in entrepreneurship at older ages, and individuals with stable work histories were also more likely to be entrepreneurs. Married or coupled respondents are more likely to be entrepreneurs relative to single, divorced, and widowed individuals. In general, these results suggest resources and stability combined with an openness to risk-taking lead to self-employment and entrepreneurship. However, these results suggest differential effects in terms of those who 'have to' work on their own and those who want to engage in self-employment.

### COMPENSATED WORK THERAPY AND OLDER VETERANS: A FIRST LOOK AT OLDER WORKERS IN VA VOC-REHAB SERVICES

M. Hunt[1,3], R. Kaczynski[2,3], S.G. Resnick[2,3], *1. VA Connecticut Healthcare System, West Haven, Connecticut, 2. VA Connecticut Healthcare System, Northeast Program Evaluation Center, West Haven, Connecticut, 3. Yale University, New Haven, Connecticut*

For over thirty years, the Veterans Hospital Administration has provided vocational rehabilitation services for Veterans with mental illnesses with or without co-occurring physical impairments. These services provided through Compensated Work Therapy (CWT) program that has three primary service components: sheltered workshops, transitional work experiences (TWEs), and supported employment (SE). CWT programs are evaluated nationally for program fidelity and outcomes by the Northeast Program Evaluation Center (NEPEC). To date, no thorough analysis of the data focusing on older (over age 50) workers has been conducted. This paper describes the population of older workers served by 163 CWT programs in VHA from FY 2006 – 2009 utilizing data from 21,795 Veteran admissions. General estimation equation analyses were used to identify correlates of three measures as indications of program success: obtaining community based work, achievement of constructive activity, and achievement of competitive employment. Characteristics and outcomes of older and younger workers are compared. Findings indicate that Veterans admitted to the program were predominantly male (96.0%). Two-thirds were employed at baseline (62.6%) or reported a serious mental health problem (63.9%). Compared to younger veterans, respondents were significantly more likely to be male (96.0% vs. 91.3%, X2=402.94, df=1, p<.001) less likely to be employed (62.6% vs. 74.0%, X2=643.70, df=1, p<.001) and more than twice as likely to be retired or disabled (8.4% vs. 3.8%, X2=416.18, df=1, p<.001). They were also significantly more likely to report having a disability (53.4% vs. 44.8%, X2=317.42, df=1, p<.001) and more likely to be homeless at (11.79%, X2=8.87, df=1, p<.01).

### IMPACT OF BENEFITS COUNSELING ON EMPLOYMENT TRANSITIONS FOR OLDER PEOPLE WITH DISABILITIES

K. Kellett, N. Shugrue, A. Kleppinger, J. Robison, *University of Connecticut Health Center, Farmington, Connecticut*

Background: Social Security Administration (SSA) disability beneficiaries often do not work or are underemployed due to the fear of losing benefits or because they misunderstand the work incentives that are part of SSA disability programs. One response to this problem has been to assist SSA disability beneficiaries in understanding their benefits and to encourage active engagement in productive roles, such as employment, as they age. Objective: This study, funded by the Centers for Medicare and Medicaid Services Medicaid Infrastructure Grant, examines the impact of benefits counseling services on consumer satisfaction and employment outcomes for individuals age 45 and older receiving SSA disability benefits and benefits counseling from a Community Work Incentive Coordinator (CWIC) through the Connecticut Bureau of Rehabilitation Services. Methods: Data from a mail survey to 571 SSA disability beneficiaries who received benefits counseling between 2007-2009 and follow-up phone calls to nonrespondents was used to explore how helpful benefits counseling was and if it enabled beneficiaries to start working, increase their hours, or increase their earnings. Results: Eighty-eight respondents met the age criteria for the study. Of these, 42% reported benefits counseling enabled them to start working, increase hours, or increase earnings. Seventy-seven percent reported they would recommend the BRS Benefits Counseling Program. Conclusion: In contrast to the stereotype of older adults as dependent unproductive members of society, our data demonstrates that benefits counseling is an important supplemental service that provides helpful employment support for older SSA disability beneficiaries who want to work and remain productive as they age.

## SESSION 345 (SYMPOSIUM)

### THE MARKETPLACE OF MEMORY

Chair: *A. Basting, UWM, Milwaukee, Wisconsin*
Co-Chair: *J.E. Graham, UWM, Milwaukee, Wisconsin*

Dementia is more than a diagnosis. It is also a complex marketplace. This symposium offers a dynamic, interdisciplinary questioning of the relationship between market forces and the experience of memory loss on several fronts. With an enormous rise in the numbers of those diagnosed with dementia predicted as the population ages, it is imperative that we examine the tensions and influences of the marketplace and the lived experience of dementia. Pia Kontos, Research Scientist at Toronto Rehabilitation, explores the tension between the regulatory landscape of long-term care, the experience, knowledge and reflective deliberations of health care practitioners and their supervisors, and the implications of this tension for person-centered dementia care. Jesse Ballenger, historian of science at Penn State University and author of The Self, Senility, and Alzheimer's Disease in Modern America, analyzes the pharmaceutical industry's marketing of drugs for memory loss. Danny George, Asst. Professor of Humanities at Penn State College of Medicine, analyzes the messages about memory loss inherent in the marketing of memory-enhancing video games/programs. Keith Diaz Moore examines the facilities created for people with memory loss and how these in turn shape a cultural understanding of the experience of dementia. Sally Chivers, Asst. Professor at Trent University, analyzes popular films and their representations of memory loss. Janice Graham, Canada Research Chair in Bioethics, will serve as discussant, with a special focus on the ethical issues entwined in the presentations.

### NEURONS IN NEIGHBORHOODS: FINDING A MORE SUSTAINABLE APPROACH TO COGNITIVE WELLNESS ACROSS THE LIFESPAN

D. George*, Penn State College of Medicine, Hershey, Pennsylvania*

In the marketplace of memory, the predominance of slogans such as "train your brain", "maintain your brain", and "optimize your neurons" contribute to a largely neuro-centric focus on late-life wellbeing. However, humans have evolved, not as disembodied brains, but as members of social networks. Therefore, the most successful pathways to cognitive (and general) wellness across the lifespan may be relational rather than obtained through mere isolated consumption of brain-training products. The language of the memory marketplace will therefore be deconstructed, and a more expansive, humanistic focus on concepts such as lifelong-learning, acting in the world with a sense of curiosity and wonder, and appreciating the value of social play will be developed. Emphasis will be placed on seeing beyond consumer products and taking advantage of the sustainable centers of learning in one's community. Ethnographic examples from The Intergenerational School in Cleveland and the Louvre in Paris will be shared.

### REFLEXIVITY, EMBODIED PRACTICES, AND REGULATORY REGIMES IN NURSING HOMES

P.C. Kontos[1,2], K. Miller[2], G. Mitchell[3,4], C. Cott[2,1], *1. Toronto Rehabilitation Institute, Toronto, Ontario, Canada, 2. University of Toronto, Toronto, Ontario, Canada, 3. York University, Toronto, Ontario, Canada, 4. York-UHN Nursing Academy, Toronto, Ontario, Canada*

Understanding point-of-care decisions in dementia care requires that embodied care activities of personal support workers (PSWs) be understood within a context of broader regulatory logics. Using qualitative methods we explored the experiences of PSWs (n=28) and administrators (n=11) on two Alzheimer support units in Ontario, Canada. Findings indicate that point-of-care decisions were the outcome of a discordant interrelationship between PSWs' tacit knowledge and reflective deliberations, and legislative and organizational care mandates. PSWs responded to discordance by rule-breaking in order to individualize care. Unbeknownst to PSWs, rule-breaking was contingent upon administrators' case-by-case complicity as they strove to balance fears of regulatory citations with evaluations of the soundness of PSW logic. These findings have important implications for initiatives to improve care practices, and to challenge regulatory mechanisms that impede quality care.

### FAMILIAR TASKS: MEMORY LOSS AND DEMENTIA ON THE SILVERING SCREEN

S. Chivers, *Canadian Studies, Trent University, Peterborough, Ontario, Canada*

This presentation will focus on popular films about memory loss that flood the contemporary cultural marketplace. Unique in their focus on older characters, these films are often either fictional love stories disrupted by the unusual behavior of a spouse (examples include *Iris*, *The Notebook*, *Away from Her*, and *A Song for Martin*) or personalized medical narratives that focus on care (examples include HBO's *The Alzheimer's Project*, PBS's *The Forgetting* and *The Future of Alzheimer's*, and the NFB's *Memory Adrift*). Both the fiction films and the documentary films highlight what dementia introduces into human relationships. Alongside the changing memory status of the "patient," film viewers witness family members' reminiscences that establish the centrality of conventional memory function. The paper will draw attention to how such films market themselves to and carefully shape the expectations of an aging audience. After attending the symposium, audience members will be able to evaluate how the films gently introduce viewers to possible futures while subtly emphasizing a desire to preserve memories. They will also be able to discuss other ways to situate memory that are counter to these dominant stories of loss.

### IN PLACE, OUT OF PLACE: THE ROLE OF PLACE IN SHAPING PERCEPTION OF THE DEMENTIA EXPERIENCE

K. Diaz Moore, *Architecture, University of Kansas, Lawrence, Kansas*

All too often, manifestations of dementia are viewed from an etiological perspective and yet the dementia experience is exceptionally varied. The progressive decline of dementia is documented through observable manifestations, and yet Gubrium (1978) identified thirty years ago that "what behavior is spoken of or recorded as senile depends on place." This presentation will focus on the hidden and often coercive role that place plays in the dementia experience. Focusing on the concept of place rules, which serve to summarize the recurring and expectant relationships between activity and setting, this presentation will discuss the situations in which we place people with dementia that may, in and of themselves, foster certain manifestations considered indicative of a decline in functional status. As such, place rules are a powerful, qualitative concept that highlights the relationship between the environment and observable functional competence as hypothesized by Lawton and Nahemow (1973).

## SESSION 350 (SYMPOSIUM)

### WHAT IS NEW ABOUT OLD AGE STEREOTYPES AND IMAGES OF AGING?

Chair: *D. Kotter-Gruehn, Department of Psychology, North Carolina State University, Raleigh, North Carolina*

Discussant: *T.M. Hess, Department of Psychology, North Carolina State University, Raleigh, North Carolina*

Negative images and stereotypes about age and aging are highly prevalent in Western societies and often result in age discrimination. Furthermore, age stereotypes and negative views of aging have been shown to negatively influence older adults' attitudes and behavior as well as their well-being, health, and longevity. The aim of this symposium is to present recent findings pertaining to age stereotypes and images of aging assessed in multiple contexts. Using questionnaire data from employees of several work teams, Bowen & Staudinger address the question whether images of aging in the work context moderate age-differences in the motivation to strive towards possible gains and improvements (promotion orientation). Kotter-Gruehn & Hess present results from an experimental study in which they examined whether young, middle-aged, and older adults' self-perceptions of aging can be manipulated through the activation of age stereotypes. Levy presents evidence for a stereotype matching effect (i.e., the effect that age stereotypes have a stronger impact on older individuals when the stereotype content corresponds to the outcome) and she discusses how this might generate expectations that become self-fulfilling prophecies. Wurm and colleagues use survey data to investigate the question whether the detrimental effect of a negative view on ageing depends on the attribution of health problems to age or to illnesses. Our discussant Thomas Hess will integrate the four papers and discuss the implications that age stereotypes and images of aging have at different ages and in different contexts of life.

### IMAGES OF AGING IN THE WORKPLACE MODERATE AGE DIFFERENCES IN PROMOTION ORIENTATION

C. Bowen, U.M. Staudinger, *Jacobs Center on Lifelong Learning and Institutional Development, Bremen, Germany*

It is a common finding in the adult development literature that the motivation to strive towards possible gains and improvements (promotion orientation) decreases with age. Building on experimental research that has found a relationship between activated stereotypes and motivational orientation, we investigated whether images of aging in the work context would moderate age differences in promotion orientation. Cross-sectional questionnaire data from $n = 337$ employees (aged 19 – 64 years) in $k = 36$ work teams indicated that perceptions of the *age climate* (i.e., the positivity of the image of older workers within an individual's company) moderated age-related differences in promotion orientation. Specifically, the typical pattern of lower promotion orientation at higher ages was only observed among those individuals who perceived a less positive age climate. Perceiving a positive age climate appeared to buffer against an age-related decline in promotion orientation.

### CONTRAST OR ASSIMILATION EFFECT? THE IMPACT OF AGE STEREOTYPES ON SELF-PERCEPTIONS OF AGING

D. Kotter-Gruehn, T.M. Hess, *Department of Psychology, North Carolina State University, Raleigh, North Carolina*

How satisfied people are with their age(ing) and how old they feel are important correlates of well-being and health in old age. Given these beneficial effects, the question arises whether positive self-perceptions of aging (SPA) can be promoted. The present study addressed this question by examining whether the activation of positive or negative age stereotypes leads to more positive or negative SPA, respectively. 60 young, 60 middle-aged, and 60 older adults were presented with either positive, negative or no age stereotypes. Before and after the stereotype activation, SPA was measured. Results indicate that especially in old age, the activation of negative stereotypes does not lead to more negative but to more positive SPA. Interestingly, the confrontation with positive age stereotypes did not make participants more satisfied with their own aging. Results will be discussed in terms of assimilation and contrast effects and the efficacy of stereotype priming.

### THE STEREOTYPE-MATCHING EFFECT: GREATER INFLUENCE ON FUNCTIONING WHEN AGE STEREOTYPES CORRESPOND TO OUTCOMES

B.R. Levy, E. Leifheit-Limson, *Yale University, New Haven, Connecticut*

Older individuals assimilate, and are targeted by, contradictory positive and negative age stereotypes. It was unknown whether the influence of stereotype valence is stronger when the stereotype content corresponds to the outcome domain. We randomly assigned older individuals to either positive-cognitive, negative-cognitive, positive-physical, or negative-physical subliminal-age-stereotype groups and assessed cognitive and physical outcomes. As predicted, when the age stereotypes corresponded to the outcome domains, their valence had a significantly greater impact on cognitive and physical performance. This suggests that if a match occurs, it is more likely to generate expectations that become self-fulfilling prophecies. Findings will be discussed in the context of newly-described stereotype embodiment theory.

### AGE OR ILLNESS – TO WHAT DO OLDER PEOPLE ATTRIBUTE SYMPTOMS AND DOES THIS AFFECT FUNCTIONAL HEALTH?

S. Wurm[1], B. Schüz[1], L. Warner[1,2], J.P. Ziegelmann[2], C. Tesch-Roemer[1], *1. German Centre of Gerontology, Berlin, Germany, 2. Freie Universität, Berlin, Germany*

Older people with chronic illnesses experience losses in their functional health (FH). Longitudinal studies showed that a negative view on own aging is detrimental to health. It is an open question whether this detrimental effect depends on the attribution of health problems to age or to illnesses. A longitudinal study in N = 309 older people (65+) with multiple illnesses assessed FH, self-perceptions of aging (SPA) and attributions of symptoms to age or illnesses. FH of people who viewed aging as accompanied by physical losses declined over a 6-month period ($\beta = -.11$; $p<.05$). Moderated regression analyses showed that this negative effect is smaller for those who attribute their health problems to age and not to illnesses ($\beta=.09$; $p<.05$). This emphasizes the role of SPA on health. The positive effects might be due to that people who expect aging-related rather than illness-related losses are better able to maintain beneficial health behaviors.

## SESSION 355 (SYMPOSIUM)

### ADVANCING MUSCLE MECHANISTIC KNOWLEDGE UNDERLYING CLINICAL PHENOTYPES IN ELDERLY WITH CHRONIC DISEASE

Chair: *B. Nicklas, Wake Forest University School of Medicine, Winston-Salem, North Carolina*
Co-Chair: *A. Ryan, University of Maryland, Baltimore, Maryland*
Discussant: *R. Fielding, Tufts University, Boston, Massachusetts*

Loss of muscle mass/strength is a common pathway contributing to physical disability in the elderly, regardless of the presence of chronic disease. While specific behavioral and/or pharmacological therapies in older persons may prevent sarcopenia, there are little data from clinical trials in the elderly designed to assess whether responses to an intervention are mediated by adaptations in skeletal muscle. This is due, in part, to the scarcity of inclusion of skeletal muscle acquisition/biopsy, and subsequent measurement of in vitro muscle characteristics, as secondary outcomes in randomized, clinical trials (RCT) with sample sizes large enough to detect effects on clinical outcomes. This symposium presents data from three Claude Pepper Centers that are assessing the role of lifestyle interventions on both clinical and mechanistic outcomes. The first presentation shows data on the acceptability, yield and safety of the biopsy procedure itself among older adults with diverse co-morbidities. The next presentation describes the utility of using gene microarrays to generate mechanistic hypotheses relating muscle properties to a unique clinical finding from a RCT in obese elderly. The third describes how altered skeletal muscle of the hemiparetic leg of stroke survivors is related to several clinical phenotypes, while the final talk presents data suggesting that an impaired anabolic response of aged muscle to overload is related to excess lipid infiltration. Collectively, these findings point to the importance of procuring muscle and measuring in vitro muscle characteristics as secondary outcomes in large-scale trials examining interventions to prevent sarcopenia in the elderly.

### FEASIBILITY, EFFICACY AND SAFETY OF SKELETAL MUSCLE ACQUISITION IN FRAIL ELDERLY WITH CO-MORBIDITIES

M.F. Lyles[1], K. Murphy[1], B. Nicklas[1], C. Hafer-Macko[2], A. Ryan[2], *1. Wake Forest University School of Medicine, Winston-Salem, North Carolina, 2. University of Maryland, Baltimore, Maryland*

Despite the importance of deficits in muscle metabolism/function as contributors to disability in the elderly, acquisition of muscle tissue via percutaneous needle biopsy has been historically used for research studies in young and/or healthy persons. Certain research groups are increasingly using this technique in the context of clinical trials in the frail elderly with chronic diseases; yet, there are presently little data on the feasibility, safety, and tissue yield of the procedure in this population. We will present such data from biopsies performed in >400 adults (65-85 yrs) with stroke, osteoarthritis, heart failure, COPD or obesity who were enrolled in separate clinical trials. The mean tissue yield differs by patient type and by paretic/nonparetic legs in stroke patients. To date, there have been no complications which required emergency treatment, and the overall rate of minor complications is <8%. The presentation will discuss adaptations used to make this technique more suitable for frail elderly.

### USING GENE MICROARRAYS TO DISCOVER SKELETAL MUSCLE MECHANISMS UNDERLYING CLINICAL RESPONSES TO DIET AND EXERCISE INTERVENTIONS

R. Loeser, J. Fetrow, J. Chou, B. Nicklas, S.B. Kritchevsky, *Wake Forest University School of Medicine, Winston-Salem, North Carolina*

In a clinical trial, we noted an interaction of pioglitizone use with resistance training (RT) and weight loss (DIET) such that the older (65-79 yrs), obese adults randomized to DIET+PIO+RT experienced a two-fold greater improvement in muscle power than those randomized to DIET+RT. The mechanism for this observation could be related to altered gene expression in muscle in response to stimulation of PPARgamma by pioglitizone. Thus, we performed gene microarrays (Affymetrix U133A 2.0) using RNA isolated from vastus lateralis muscle of 12 subjects. The raw expression data were normalized using the Systematic Variation Normalization (SVN) method. Genes with significant detection were evaluated for significant changes in expression between the pre- and post-intervention timepoints—107 genes were up-regulated and 119 genes were down-regulated. Two methods of computational analysis were performed to cluster genes based on intervention groups. Genes of interest (n=7) were then chosen for quantification by real-time PCR.

### ALTERED HEMIPARETIC SKELETAL MUSCLE OF STROKE SURVIVORS: RELATIONSHIP WITH CLINICAL PHENOTYPES

A. Ryan, C. Hafer-Macko, *University of Maryland, Baltimore, Maryland*

Stroke leads to persistent neurological deficits that impair function and promote physical inactivity. Low peak aerobic capacity is associated with reduced thigh muscle mass and greater gait deficits illustrating the importance of muscle mass to physical fitness in stroke. Our data indicate significant muscular atrophy of hemiparetic thigh compared to non-paretic thigh and higher intramuscular fat area. Myosin heavy chain (MHC) gel electrophoresis of bilateral vastus lateralis shows a remarkable shift in the proportion of fast MHC isoforms in the hemiparetic but not the non-paretic leg. The proportion of fast MHC isoform in the hemiparetic leg is strongly negatively associated with slower self-selected walking speed. Inflammatory pathways including TNFalpha mRNA levels are elevated in hemiparetic muscle compared to non-paretic and controls. New evidence indicates myostatin mRNA levels, a significant regulator of muscle development and size, are higher on paretic than non-paretic leg. Exercise rehabilitative strategies may improve these muscle alterations.

### DECREASED MUSCLE PROTEIN CONTENT IS ASSOCIATED WITH DEFECTIVE LIPID METABOLISM IN AGING SKELETAL MUSCLE

D.A. Rivas, E. Morris, R. Fielding, *Tufts University, Boston, Massachusetts*

Increased intramuscular lipid content has been noted in lean and obese elderly persons and is thought to be associated with insulin resistance and decreased muscle quality. Furthermore, the impaired anabolic response of aged skeletal muscle to muscle contraction may also be related to excess lipid infiltration. However, it is still unknown if lipid accumulation has a mechanistic role in the age-associated loss of muscle mass. We have determined the effect of 28 days of overload on the storage of intramuscular lipids and regulators of lipid synthesis in the plantaris of young and aged Fischer 344 x Brown Norway rats subjected to bilateral synergist ablation of two thirds of the gastrocnemius muscle or sham surgery. Data will be presented suggesting that the regulation of lipid metabolism is impaired in aging skeletal muscle and does not respond to mechanical overload via synergist ablation.

## SESSION 360 (SYMPOSIUM)

### BEING OUT OF SYNCH: INFORMAL CAREGIVERS' PERCEIVED NEEDS AND UNMET EXPECTATIONS IN END-OF-LIFE CARE TRAJECTORIES

Chair: *J. Penrod, The School of Nursing, The Pennsylvania State University, University Park, Pennsylvania*
Discussant: *J.E. Hupcey, The Pennyslvania State University, Hershey, Pennsylvania*

Informal caregivers are instrumental partners-in-care with health care providers who manage trajectories of life-limiting illnesses. In many cases, family caregivers provide or manage the everyday care that supports or comforts the person facing a complex trajectory toward the end of life. Despite their shared goals in care, the interface between the informal family caregiver and formal health care provider is often limited to brief office visits across the illness trajectory that target the medical management of the presenting illness. This ethnographic study examined the interactions between informal and formal caregivers during brief office visits in three distinct models of care for complex end-of-life care trajectories. Paper 1, Being Out of Synch, explores the notion of disconnects—that is, disruptive times when expectations regarding the role of the formal provider or perceived priorities of care are unmet. Paper 2, The Informal Caregivers' Journey, presents a model for understanding end-of-life caregiving and centers on disconnects between the phase-specific needs of the informal caregiver and the attributes of the formal care delivery system. Paper 3, Pathways to the End of Life, advances understanding of the course and duration of phases of caregiving in distinct death trajectories, then focuses on the types of disconnects related to timing. Finally, Paper 4, A Clash of Culture, examines characteristics of the culture of care in dominant models of end-of-life care delivery that opens opportunities to either connect or disconnect with family caregivers across the course of care.

### BEING OUT OF SYNCH

J. Penrod[1], J.E. Hupcey[2], S.J. Loeb[1], *1. The School of Nursing, The Pennsylvania State University, University Park, Pennsylvania, 2. The Pennsylvania State University, Hershey, Pennsylvania*

Despite the instrumental role of informal caregivers in prolonged end-of-life care trajectories, these partners-in-care are often neglected as care recipients. This paper describes a large ethnographic study of the interface between informal and formal caregivers across different trajectories of living with and dying from a life-limiting illness. Through an examination of ongoing office visits, the notion of disconnects—that is, disruptive times when the informal and formal caregivers fall out of synch with each other and their partnered roles diverge. Informal caregivers, living with care demands, perceive care needs that subsequently drive expectations of the provider and of care. Expectations of the formal care provider include the style of interaction and the scope of concern. Expectations of care include prioritization of the domains of care (e.g., symptom management or financial issues) and timing. Disconnects are highlighted as a divergence of perspectives when informal caregivers' expectations are unmet.

### THE INFORMAL CAREGIVERS' JOURNEY

M. Kanaskie[2], J. Penrod[1], J.E. Hupcey[2], S.J. Loeb[1], *1. The School of Nursing, The Pennsylvania State University, University Park, Pennsylvania, 2. The Pennsylvania State University, Hershey, Pennsylvania*

Understanding the divergence of perspectives that is manifest as a "disconnect" is contingent upon understanding the informal caregivers' experience of providing care during advanced illness and through death. End-of-life caregiving is a profound, life-altering experience that consists of a rather universal series of phases demarcated by standard transitions in the illness/care trajectory. A model of end-of life caregiving derived in a grounded theory study is presented to highlight the experiential features of end-of-life caregiving. Four phases, punctuated by three transitions, evolve around the core variable of seeking normal. From this perspective, disconnects are driven by uncertainties that are not addressed or pre-empted by the care providers. These disruptive occurrences are related to phase-specific needs of the informal caregiver and are often rooted in the attributes of the formal care delivery system.

### PATHWAYS TO THE END OF LIFE

P.Z. Shipley[1], J. Penrod[1], J.E. Hupcey[2], S.J. Loeb[1], *1. The School of Nursing, The Pennsylvania State University, University Park, Pennsylvania, 2. The Pennsylvania State Univ, Hershey, Pennsylvania*

In this paper, the model of EOL Caregiving is super-imposed on three distinct death trajectories to advance a deeper understanding of how the phases of caregiving are molded by care demands across the trajectory of living with and dying from varied life-limiting conditions. The Expected death trajectory features a recognized course toward death initiated by the diagnosis of a terminal illness. In the Mixed death trajectory, care initially focuses on the treatment of a life-threatening condition, then shifts dramatically toward supportive end-of-life care. In contrast, the Unexpected death trajectory is highlighted by repeated episodic care for a life-threatening condition that is known to limit life, but is not recognized as terminal. From this perspective, patterns of disconnects are related to timing—when the informal caregiver falls out of synch with the care providers' interpretation of the trajectory.

### A CLASH OF CULTURE

B. Baney[1], J. Penrod[1], J.E. Hupcey[2], S.J. Loeb[1], *1. The School of Nursing, The Pennsylvania State University, University Park, Pennsylvania, 2. The Pennsylvania State University, Hershey, Pennsylvania*

Understanding the informal caregivers' experiences across varied trajectories is necessary but insufficient for unraveling the complexity of being "out of synch." Typically, ongoing care is rendered through an outpatient delivery system that is organized around medical specialties that focus on the care recipient in the role of patient. Findings of the ethnography reveal that specialty care settings manifest a culture of care that reflects inherent values and beliefs regarding the illness experience, informal caregiving, and ultimately, the end of life. Three dominant models of end-of-life care delivery were identified: Dominant Provider; Cooperative Network; and Interdisciplinary Team. Informal caregivers are enmeshed in these models of care delivery. The characteristics of each model (including: the assumed role of the health care provider, conceptualization of the patient system, focus of the visit, and flow of care) opens opportunities to either connect or disconnect with informal caregivers across the course of care.

## SESSION 365 (PAPER)

## EPIDEMIOLOGY OF PHYSICAL FUNCTION

### KNEE OSTEOARTHRITIS AND RISK OF INDOOR AND OUTDOOR FALLS IN OLDER ADULTS: THE MOBILIZE BOSTON STUDY

U. Nguyen[1,2], Y. Zhang[2], L. Quach[1], D. Kiel[1,6], S.G. Leveille[3], R.H. Shmerling[4], C.A. Oatis[5], M. Hannan[1,6], *1. Hebrew SeniorLife Institute for Aging Research, Boston, Massachusetts, 2. Boston University School of Medicine, Boston, Massachusetts, 3. University of Massachusetts Boston, Boston, Massachusetts, 4. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 5. Arcadia University, Glenside, Pennsylvania, 6. Harvard Medical School, Boston, Massachusetts*

Symptomatic osteoarthritis (SxOA) of the knee and falls are both common in older adults and limit mobility. A few studies have shown a link between knee SxOA and falls, and recent research suggests that risk factors may differ by outdoor and indoor falls. To our knowledge, no study has examined whether knee SxOA has a different effect on outdoor vs. indoor falls. We tested this hypothesis in the participants of the MOBILIZE Boston Study, a population-based cohort of community-dwelling older adults. Falls data, including where falls occurred, were collected using monthly calendars. We used negative binomial regression to estimate the effect of knee SxOA on risk of outdoor and indoor falls (separately and combined), adjusting for age, sex, BMI, co-morbidities, medications and falls history. Of 470 women and 269 men (mean age: 78 years; mean BMI: 27.3), 25% had ACR-defined clinical knee SxOA. Over 2.3 years of follow-up, 453 people had at least 1 fall. Mean annualized outdoor falls rates were 0.51 and 0.35 for participants with and without knee SxOA, respectively. The corresponding indoor falls rates were 0.55 and 0.40. Compared with people without knee SxOA, those with knee SxOA had a 30% increased risk of outdoor falls (RR=1.3, 95% CI:1.0-1.7), and a 20% increased risk for indoor falls (RR=1.2, 95% CI:0.9-1.5), adjusting for confounders. The rate ratio for the effect of knee SxOA on risk of all falls was 1.2 (95% CI:1.0-1.5). Having knee SxOA increased the risk of falls, similarly for outdoor and indoor falls.

### PHYSICAL FUNCTION LIMITATIONS AMONG OLDER ADULTS WITH PREDIABETES

P.G. Lee[1,2], C. Cigolle[1,2,3], W.H. Herman[1], Y. Lee[1], C. Blaum[1,2], *1. Internal medicine, University of Michigan, Ann Arbor, Michigan, 2. VA Healthcare System GRECC, Ann Arbor, Michigan, 3. University of Michigan Department of Family Medicine, Ann Arbor, Michigan*

Older adults with diabetes are at increased risk for functional limitations compared to those without diabetes. Prediabetes is prevalent among older adults; its association with functional limitations is unknown. We hypothesized that older adults with prediabetes are at increased risk for functional limitations. We analyzed the 2006 wave of the Health and Retirement Study, a longitudinal, nationally-representative survey of adults aged ≥53 years. Hemoglobin A1C was measured from blood samples. We considered respondents with A1C 5.7-6.4% and without self-reported diabetes to have prediabetes. Physical function measures included activities of daily living (ADLs), instrumental activities of living (IADLs), upper body function (lift 10lb, pick up dime, reach/extend arms), and lower body function (walk several blocks, climb stairs, stoop /crouch/ kneel). Logistic regression analyses were performed to compare functional limitations of respondents with prediabetes and without diabetes. Twenty-eight percent of the respondents had prediabetes, representing 21 million older adults. The proportions of respondents with prediabetes with limitations in ADLs, IADLs, upper body function, lower body function, and either upper/ lower body function were 14%, 12%, 30%, 53%, and 57%, respectively. Compared to respondents without diabetes, the unadjusted odds ratio of respondents with prediabetes having upper/lower body function limitations was 1.38 (p<0.001), and 1.15 (p=0.08) after adjusting for demographic variables. Our study found that functional limitations are prevalent among older adults with prediabetes. Functional limitations among older adults with prediabetes have implications for physical activity programs whose aim is to delay the onset of diabetes.

### THE ASSOCIATION BETWEEN MIDLIFE BODY MASS INDEX AND BRAIN VOLUME IN LATE LIFE: AGE GENE/ENVIRONMENT SUSCEPTIBILITY - REYKJAVIK STUDY

M. Chang[1], J. Saczynski[2], S. Sigurdsson[3], V. Gudnason[3,4], T.B. Harris[5], L.J. Launer[5], P.V. Jonsson[1,4], *1. Landspitali University Hospital, Reykjavik, Iceland, 2. University of Massachusetts Medical School, Worcester, Massachusetts, 3. Icelandic Heart Association, Kopavogur, Iceland, 4. University of Iceland, Reykjavik, Iceland, 5. National Institute on Aging, Bethesda, Maryland*

Background: High body mass index (BMI) in midlife is a risk factor for dementia, and total brain volume is associated with dementia risk. However, little is known about the association between midlife BMI and late-life brain volume. We examined an association between midlife BMI and late-life brain volume. Methods: A population based cohort of men and women (born 1907–1935) participated in the Age Gene/Environment Susceptibility - Reykjavik Study. The interval between midlife BMI and late-life cognitive function was 26 years. Midlife BMI was categorized as 1) normal (BMI 18.5 to 24.9; 56.9%), 2) overweight (BMI 25 to 29.9; 34.0%), and 3) obese (BMI 30 or more; 9.1%). Main outcome measure was a total brain volume (TBV, sum of gray matter, white matter, and white matter lesion) assessed using magnetic resonance imaging (MRI). Results: Total population is 4552 participants (women = 58%, dementia = 4.4%), and analyses are based on 4354 subjects after excluding individuals with dementia. Compared to the normal BMI group, overweight and obese group had higher TBV (overweight: $\beta$ = 3.15, not significant, obese: $\beta$ = 10.78, $p < 0.05$) after controlling for demographic, behavioral and cardiovascular factors, head size, physical activity, and apolipoprotein E genotype. Conclusion: Being overweight or obese in midlife is associated with higher total brain volume 26 years later. Further research needs to examine this association by different area and type of brain tissue.

### CHRONIC MUSCULOSKELETAL PAIN AND SLEEP PROBLEMS IN THE OLDER POPULATION

Q. Chen[1], L. Hayman[1], R.H. Shmerling[2], J.F. Bean[3], S.G. Leveille[1,2], *1. University of Massachusetts Boston, Boston, Massachusetts, 2. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 3. Spaulding Cambridge Rehabilitation Outpatient Center, Boston, Massachusetts*

Although chronic pain and sleep difficulty are common problems affecting older adults, the relationship between pain and sleep is poorly understood. We evaluated pain severity and location in relation to sleep problems in 765 participants aged >64y from the population-based MOBILIZE Boston Study. Pain severity was measured using the Brief Pain Inventory(BPI) severity subscale. Pain location was grouped according to no pain, single site, >2 sites, and widespread pain (upper and lower extremities and back pain). We measured 3 aspects of sleep difficulty using items from the CESD (trouble getting to sleep, sleep more than usual, and restless sleep). At the baseline interview, prevalence of trouble getting to sleep according to BPI severity was 17.8%, 19.7%, 32.0%, and 37.0% for the lowest to highest pain severity quartiles, respectively. Similar relationships between pain and sleep were observed across sleep measures according to pain severity and location. In multivariable logistic regression models, chronic pain was associated with trouble sleeping (≥1d/week) (widespread pain, OR=2.55, 95% CI, 1.43-4.54; multisite pain OR=2.38, 95% CI, 1.48-3.83; and single site pain, OR=1.77, 95%CI, 1.10-2.87, each compared with no pain). Similar associations were observed across each sleep measures. With specific musculoskeletal sites alone or in combination with other pain sites, only modest associations were observed with sleep problems. In conclusion, widespread or other multisite pain and moderate to severe pain are strongly associated with sleep difficulty in older adults. Further research is needed to better understand the burden and consequences of pain-related sleep problems in the older population.

# SESSION 370 (PAPER)

## HOSPITALIZATION AND REHOSPITALIZATION

### DO DEMENTIA PATIENTS ADMITTED TO HOSPITALS WITH HIGHER RATES OF FEEDING TUBE INSERTION HAVE IMPROVED SURVIVAL?

S. Cai[1], P. Gozalo[1], S. Mitchell[2], S. Kuo[1], J. Bynum[3], V. Mor[1], J.M. Teno[1], *1. Brown University, Providence, Rhode Island, 2. Harvard Medical School, Boston, Massachusetts, 3. Dartmouth Medical School, Lebanon, New Hampshire*

Objective: Hospitals vary feeding tubes (FT) insertion rates for nursing home residents (NHR) with dementia. Our goal is to examine whether there is improved survival when a NHR with advance cognitive impairment is admitted to hospitals with sustained higher rate of FT insertions. Methods: Using the 2000-2007 Minimum Data Set and Medicare Claims Files, we characterized the ranking of hospitals' feeding insertion rate and whether the rate was increasing, staying the same, or reducing. A Total of 9 categories were formed by comparing the rates of FT insertion among 1,772 acute care hospitals between 2000-2003 and 2004-2007 time periods. A multivariate random effects model examined the 1- and 6-month mortality, adjusting for NHR characteristics. Results: A total of 56,571 NHR during 2004-2007 (average age 84, 68 % female) were admitted to 1,772 acute care hospitals (16.5% for-profit, 37.5% medical school affiliation). Comparing the two time periods, 20.6 % of the hospitals remained at sustained high level of FT insertion (top tercile) while 18.5% remained at sustained low levels of feeding tube insertion (bottom tercile). After adjusting NHR characteristics, we found no significant association between residents' survival and the level of hospital FT use. For example, the adjusted odds-ratio of 1 month survival was 0.97 (95% CI: 0.906-1.047) for NHR in 365 hospitals with sustained high level of FT insertions compared to NHR in the 328 institutions with a sustained low rate of FT insertions. Conclusion: Demented NHR admitted to hospitals with sustained high FT insertions have no survival advantage.

### PAYMENTS AND MORTALITY IN 30-DAY MEDICARE REHOSPITALIZATIONS TO THE SAME AND TO DIFFERENT HOSPITALS

A. Kind, C. Bartels, M. Mell, M.A. Smith, *University of Wisconsin, Madison, Wisconsin*

Background: About one-quarter of rehospitalized Medicare patients are admitted to hospitals different from their original, and proposed Medicare payment reforms may incentivize this practice further by penalizing facilities with high readmission rates. The impact that rehospitalization to different hospitals has on Medicare payments and patient mortality is unknown. Objective: To determine how rehospitalization to a different hospital impacts 30-day Medicare payments and 30-day patient mortality Sample: 5% random national sample of Medicare beneficiaries with acute-care rehospitalization within 30 days of discharge from the index hospitalization, 2005-2006 (N=74,564). Methods: Quantile (payments) and logistic (mortality) regression multivariate models included index-hospital for-profit status, discharge counts, geographic region, rural-urban commuting area and teaching status; and patient sociodemographics, disabled status and a measure of risk adjustment. Results: 22% (16,622) of the sample was rehospitalized to a different hospital. When compared to those rehospitalized to the same hospital, patients rehospitalized to different hospitals had significantly higher adjusted 30-day total payments (median additional $1398/patient [95% confidence interval = $1,162 – $1,634, p-value <0.001]) but no significant differences in 30-day mortality (adjusted risk ratio = 1.01 [0.96—1.06, p-value = 0.650]). Conclusions: Rehospitalizations to different hospital facilities are common, and are associated with significantly increased total 30-day payments without improved mortality. These factors should be carefully weighed in the creation and monitoring of Medicare rehospitalization payment reforms. We estimate that rehospitalization to different hospitals accounted for $458.7 million in excess Medicare payments over 2005-2006.

### INSTITUTIONAL CHARACTERISTICS OF AMERICAN NICHE HOSPITALS

M. Rosenberg, M. Boltz, N. Shabbat, E. Capezuti, *Hartford Institute for Geriatric Nursing, New York University College of Nursing, New York, New York*

NICHE (Nurses Improving Care for Healthsystem Elders) is a national program that provides the structure to develop, implement, and sustain system wide improvement in hospital care of older patients. This descriptive study compared the institutional characteristics of US NICHE hospitals (n=197) to all other US medical-surgical hospitals (n=5,520) using the 2008 American Hospital Association's (AHA) Annual Survey. NICHE hospitals are more likely to be a member of a non-profit ($p \leq 0.001$), larger (mean bed size 418.2 vs. 144.5; $p \leq 0.001$), teaching facility ($p \leq 0.01$) that is part of a network ($p \leq 0.001$), provides hospice/palliative care ($p \leq 0.001$), and have a higher RN to bed ratio ($p = 0.04$). The proportion of Medicare patients to all adult patients did not differ between the groups. Secondly, we examined institutional characteristics (AHA data) and programmatic initiatives (from the NICHE Recommitment Survey) by level of NICHE implementation: low (39.1%), some (28.6%), significant (15.8%), and high (16.5%). The highest level of NICHE was significantly ($p \leq 0.05$) associated with a higher RN to bed ratio, higher mean number of nursing assistants as well as more likely to have a geriatric service line, to provide a comprehensive geriatric assessment service, and to have attained Magnet recognition. Given that NICHE hospitals, especially those with the highest dose of NICHE implementation, are larger institutions, innovative approaches are needed to implement geriatric programs in small hospitals with fewer resources.

### REDUCING GERIATRIC REHOSPITALIZATIONS: A SUCCESSFUL CLINICAL MODEL

D. Oates, D. Kornetsky, L.B. Caruso, E. Hardt, V. Parker, *Boston University, Boston, Massachusetts*

Background: The rehospitalization of an older adult is often costly and may be an indicator of less than adequate hospital and post-discharge care. According to a Medicare Payment Advisory Commission (MedPAC) study, 75% of all 30 day rehospitalizations in 2005 were deemed potentially preventable. Boston University Geriatric Services (BUGS), an urban, academic geriatric primary care practice, which cares for medically complex, home bound, predominantly nursing home certifiable elders, employs many best practices suggested by MedPAC for reducing rehospitalizations. Methods: We conducted a retrospective cohort analysis from 2/1/06 through 12/31/08, comparing rehospitalization rates for patients of the BUGS practice 65 years old and older discharged from our dedicated inpatient geriatric service with those discharged from general medicine ward teams at our institution. We also compared the rehospitalization rates for our dedicated inpatient service with those for patients 65 years old and older discharged from other medical teams on the inpatient medical service at BMC. Results: The 30 day readmission rate for our geriatric practice's patients discharged from our dedicated, integrated inpatient service was 20.5%, compared with 22.4% for our geriatric patients discharged from non-geriatric general medical services ($p<0.0001$) and 15.35% for healthier older adults not under geriatrics care discharged from general medical services at BMC. Conclusion: A multidisciplinary, integrated geriatric practice that incorporates many of the best practices outlined by MedPAC, such as medication reconciliation, provider communication at discharge and sharing of best practices, significantly reduces 30 day rehospitalizations amongst a frail, vulnerable, geriatric population.

# SESSION 375 (POSTER)

## ISSUES IN NEUROSCIENCE AND MENTAL HEALTH

### EFFECTS OF DONEPEZIL 23 MG EXTENDED RELEASE ON SIB DOMAINS IN PATIENTS WITH MODERATE-TO-SEVERE AD

M.L. Moline[1], J. Yardley[2], Q. Wang[1], H. Zou[1], E. Brand-Schieber[1], T. Hsu[1], A. Satlin[1], *1. Eisai Inc, Woodcliff Lake, New Jersey, 2. Eisai Ltd, Hatfield, United Kingdom*

To investigate whether a higher dose of donepezil might confer cognitive benefit in patients with moderate-to-severe Alzheimer's disease (AD), patients with Mini–Mental State Exam (MMSE) score 0-20 treated ≥3 months with donepezil 10 mg were enrolled in a 24-week, randomized, double-blind, parallel-group trial. Randomized patients (n=1467) were assigned 2:1 to receive once daily donepezil 23mg extended-release tablets (23mg) or to continue on 10mg/d immediate-release tablets (10mg). The Severe Impairment Battery (SIB; cognition) and Clinician's Interview-Based Impression of Change plus caregiver input (CIBIC+; global function) were co-primary efficacy variables. At endpoint (week 24), the total SIB score showed statistically significant benefit favoring 23mg over continuing 10mg treatment (last observation carried forward [LOCF] treatment difference=2.2 points; P=.0001). For the CIBIC+, the overall change treatment difference at week 24 was not significant (0.06; P=.1789). To further characterize the significant incremental improvement of 23mg on cognition, post hoc analysis was performed on the 9 SIB domains: Language, Construction, Visuospatial Ability, Memory, Praxis, Attention, Orientation, Social Interaction, and Orientation to Name. The largest effect size was for Language (46 of 100 total points). No treatment difference was seen for Orientation, Orientation to Name, or Social Interaction, which comprise only a small number of items. Overall, treatment effect sizes for 23mg superiority (LOCF) were comparable among the domains that comprised the majority of items on the scale. These results suggest that improvement with donepezil 23mg treatment on the SIB reflects effects on a broad range of cognitive functions.

### COGNITION, EVEN IN THE NORMAL RANGE, PREDICTS FUNCTIONAL DECLINE

P. St. John[1], S. Tyas[2], P. Montgomery[1], *1. University of Manitoba, Winnipeg, Manitoba, Canada, 2. Dept. of Health Studies and Gerontology, Univeristy of Waterloo, Waterloo, Ontario, Canada*

Background: Cognitive impairment predicts functional decline. It is less clear if cognitive variation in the normal range predicts functional decline. Objective: To determine if there is a gradient effect of the Mini-mental State Examination (MMSE) score in predicting a decline in functional status over a five-year period. Population: Population-based sample of 1751 community-dwelling adults 65+ years. The sample was followed five years later; 1028 participants were still in the community and had no missing data. Measurements: Age, gender, education, living arrangements, the number of comorbid conditions, and marital status were all self-reported. Functional status was measured using the Older Americans Resource Survey (OARS), which was scored from 0 to 28. The decline was calculated in those who survived and were living in the community at time 2, and who had available data. Results: The MMSE score at time 1 was a strong predictor of functional decline five years later. This effect was a gradient seen across the entire score, extending into the normal range. There was no apparent threshold. In a linear regression model, the beta coefficient was -0.21 (p<0.001). This effect persisted in multivariate models adjusted for age, gender, education, living arrangement and the number of comorbid conditions. Conclusions: The normal range of the MMSE strongly predicts functional decline, and this effect is a gradient effect. These results support the hypothesis that cognition is a continuum.

### PREDICTORS OF MEMORY CHANGE AND STABILITY AMONG SEXAGENARIANS, OCTOGENARIANS, AND CENTENARIANS

G.D. Da Rosa[1], J. Margrett[1], P. Martin[1], L. Poon[2], *1. Human Development and Family Studies, Iowa State University, Ames, Iowa, 2. University of Georgia, Athens, Georgia*

This study investigates predictors of change in memory performance among older adults from the Georgia Centenarian Study. Participants included community-dwelling sexagenarians (N = 70), octogenarians (N = 63), and centenarians (N = 68) who were assessed during Phases 1 and 2. The test-retest period was approximately 20 months for centenarians and 60 months for sexagenarians and octogenarians. Participants completed the Expanded Paired Associate Test (EPAT; Trahan et al., 1989) and two summary scores reflecting difficulty were created (i.e., easy, hard). Individuals' standard error of measurement was used as an index to assess the degree of reliable change in memory performance over time (i.e., decline vs. stable/improve). Next, we investigated the influence of several baseline predictors including demographics (age, sex, ethnicity, education, and occupation), overall physical health rating, activities of daily living (ADL), personality (Extraversion and Neuroticism), fatigue, and depression on memory change status for each age group separately. Logistic regression analyses indicated that sex (B=-4.53, *p*=.049) and ADL ratings (B=1.73, *p*=.033) were predictive of easy EPAT change status for centenarians; men were more likely to remain stable/improve as were centenarians with higher ADL ratings at baseline. Women and highly educated centenarians were more likely to decline on the EPAT hard scores (B=-6.99, *p*=.037; B=-1.01, *p*=.05), respectively. We also found a statistical trend related to depressive symptoms and anxiety scores (B=-.347, *p*=.054; B=-1.72, *p*=.058), respectively, suggesting that centenarians with greater depressive symptoms and anxiety scores were more likely to decline on the hard EPAT task.

### EXPERIENCES DURING TRANSITIONS CAUSED BY DEMENTIA

T. Xu[1], K. Lechelt[3], L.J. Garcia[4], F. Molnar[5], W. Dalziel[5], J. Silvius[2], J.A. Triscott[3], N. Drummond[1], *1. University of Calgary, Calgary, Alberta, Canada, 2. Alberta Health Services, Calgary, Alberta, Canada, 3. Alberta Health Services, Edmonton, Alberta, Canada, 4. University of Ottawa, Ottawa, Ontario, Canada, 5. Ottawa Hospital, Ottawa, Ontario, Canada*

Decision-makers from health authorities in Canada have teamed up with researchers and clinicians to conduct a multi-centered, three-year cohort study into care for dementia, and patient and caregiver's experiences during periods of significant transition. Based on a literature review and discussion, the essential, interrelated properties of transition experiences have been identified. These include awareness, engagement, change and difference, time span, critical events, service demand, availability and utilization, expectations, sense of hazard, experience and knowledge, and environments. In addition, nine common, significant, transitional events have been identified for specific investigation: initial problem identification, first external support requirement for IADL or ADL, driving cessation, loss of financial autonomy, acute hospital admission, relocation to new community-based accommodation, entry to long term care, and end of life care. This is the first study to examine the experience, management and outcomes of transitions relating to dementia 'as they happen', emphasizing the perspectives of individuals living with dementia, whether as patients or caregivers. Patient and caregiver dyads are contacted by telephone every month to identify the presence of one of the nominated transitions, upon which an interview is immediately carried out to investigate participants' experiences and attitudes towards it. In addition, every six months a cycle of routine data collection investigates cognitive, physical, emotional and social functioning. This presentation will describe early data from the cohort - current accrual at 38 dyads with patient's mean age at 78 yrs and 37.5% male. Methodological aspects of the work will be discussed as well.

## TRANSIENT DELIRIUM AND FUNCTIONAL DECLINE IN ACUTELY ILL HOSPITALIZED ELDERS

J. Gotelli, V.J. Neelon, J. Carlson, *University of North Carolina, Chapel Hill, North Carolina*

Purpose: To compare functional status at discharge between elderly patients who developed transient (resolved by discharge) delirium during hospitalization to those who were never delirious, and to investigate the impact of components of delirium on discharge function. Methods: Seventy-nine hospitalized elders were grouped by delirium status measured by the NEECHAM confusion scale (range 0-30). Functional status at discharge (Katz ADL scale) adjusted for baseline functional status (OARS IADL and PADL) and illness severity (APACHE II) was compared between 26 patients who were delirious (NEECHAM <25) and 53 who were not delirious. We looked at multivariate associations between patient characteristics and Katz scores at discharge. Findings: Those who experienced transient delirium showed: 1) more functional impairment at discharge (Katz score 8.18 vs. 10.67 p=0.01); 2) longer hospital stays (10.23 vs. 4.63 days p<0.01); 3) higher rates of chronic cognitive impairment (9/26 patients vs. 6/53 patients p=0.02); 4) higher disease burden scores (14.5 vs. 12.15 p=0.04); 5) lower pre-admission IADL scores (8.96 vs. 11.71 p=0.02). Fully adjusted multivariate associations with Katz scores (dependent variable) were significant for the information processing components of the NEECHAM (subscale 1) (coefficient 0.63087 t score 2.64 p=0.01). Discussion: Even transient delirium had a negative impact on functional status in this sample. It is not clear how impaired IADL function before admission and transient delirium interact to worsen ADL function at discharge. It is possible that delirium, through an abrupt insult on the neural networks of executive control, imparts a lasting effect on function.

## THE LIVING WITH MEMORY LOSS PROGRAM: A STUDY OF THE EFFECTIVENESS OF A SUPPORT SERVICES REFERRAL PROGRAM FOR INFORMAL DEMENTIA CAREGIVERS

S. Bass[2], F. Moise[1,2], T. Huh[2], K. McConnell[2], J. Timbs[2], H. Doneux[3], E. Edgerly[2], K. Skultety[2], *1. Psychology, Pacific Graduate School of Psychology at Palo Alto University, Palo Alto, California, 2. Palo Alto Health Care VA System, Palo Alto, California, 3. Alzheimer's Association, Palo Alto, California*

Introduction: This study examined the effectiveness of, a community referral program, in partnership with a VA Healthcare System to impact caregivers' perceived knowledge about dementia and community resources, use of resources and distress. Methods: Out of 33 caregivers who enrolled in the program, 24 participants (15 spouses, 9 children) completed pre and post evaluations. Mean age of caregivers was 65 (SD=14). Caregivers were assessed by phone before and after program enrollment. Level of knowledge, willingness to participate in the program and level of burden and satisfaction were evaluated using questionnaires developed for the study and The Zarit-Burden Scale (Zarit, 1995). Results: Caregivers demonstrated significant increase in knowledge about community program services, (Pre Mean= 1.97; Post Mean=4.97, t (28), p<. 001) and willingness to recommend others to the program (Pre Mean=3.10; Post Mean= 3.72, t (28), p= <.01). However, although there was no significant decrease in the level of burden (Pre Mean=12.62; Post Mean= 12.34, t (28) p <.77), majority of caregivers reported feeling less stressed (80%) and isolated (70%), and were more likely to use community services (88%). Conclusion: Partnerships between community programs and health care systems increase access to needed support services. Results suggest that such access may provide several benefits to informal caregivers including awareness and willingness to use community based services, which may lead to decrease in subjective stress and sense of isolation.

## NEUROPSYCHOLOGICAL TEST PERFORMANCE AND INFORMANT REPORTS IN CLINICIANS' DIAGNOSIS OF COGNITIVE FUNCTIONING ACROSS CULTURAL GROUPS

P. Sayegh[1], B.G. Knight[2], *1. Department of Psychology, University of Southern California, Los Angeles, California, 2. University of Southern California, Los Angeles, California*

We used a sample of 145 Hispanic and 527 non-Hispanic White patients evaluated at the University of Southern California Alzheimer's Disease Research Center to test whether neuropsychological test performance or informant reports more strongly predicted clinicians' diagnosis of normal cognition or dementia across patients from two ethnic groups evaluated at a memory disorders clinic. Informant reports were measured using scales that assessed the patients' neuropsychiatric symptoms and functional abilities (i.e. instrumental activities of daily living). When controlling for age, gender, and education, results revealed that better neuropsychological test performance was associated with a diagnosis of normal cognitive functioning by clinicians among all patients. However, this association was stronger among non-Hispanic White patients as compared to Hispanic patients. The weight of informant reports in clinicians' diagnoses did not differ significantly across these two ethnic groups. These findings suggest that clinicians may weigh neuropsychological test performance to a lesser degree among Hispanic patients when diagnosing cognitive functioning due to language and education level issues associated with these tests and that they may weigh informant reports to a similar degree across groups.

## TRANSLATING RESEARCH INTO PRACTICE: A THEORY SYNTHESIS APPROACH USING *REACH* (RESOURCES FOR ENHANCING ALZHEIMER'S CAREGIVERS HEALTH) AND *WARP* (WHALL AGGRESSIVE RISK PROFILE)

V.H. Tyrrell, *Oakland University, Rochester, Michigan*

With an aging US population, more people will develop dementia and these increased health care consumer-numbers will present a significant challenge to health care systems and to provider-capacity. People with dementia (PWD) often demonstrate anxiety and aggressive behaviors when demands exceed their understanding (e.g., during daily care); such behaviors negatively impact the caregiver and the PWD. The author reviewed the existing literature for interventions designed to ameliorate anxiety and aggression in PWD. The first documented usage of the term dementia is discussed (Pinel, 1806) along with grand, middle-range and practice-level nursing theories, including Nightingale's (adding her own family care-giving experiences), the Progressively Lowered Stress Threshold (PLST) (Hall and Buckwalter, 1987), and the Need-driven Dementia-compromised Behavior (NDB) (Algase et al., 1996) models. Using the theory synthesis method of Walker and Avant (2005), two models, REACH (Resources for Enhancing Alzheimer's Caregiver Health; Burgio et al., 2009) and WARP (Whall Aggressive Risk Profile; Whall, 2009) were synthesized while integrating two nursing models, the Preferred Implicit Memory (PIM) (Harrison, Son, Kim and Whall, 2007) and Multi-Sensory Environments (MSE) (Riley-Doucet, 2009), with a goal to better delineate which PWD and what nursing intervention(s) are more likely to relieve caregiver burden and lessen aggression in people with dementia. Future adaptation of REACH and WARP (using PIM and MSE) into the language of NIC (Nursing Interventions Classification; Bulechek, Butcher and Dochterman, 2008) and NOC (Nursing Outcomes Classification; Moorhead, Johnson, Maas, and Swanson, 2008) is suggested to further facilitate research translation into practice to promote positive care-recipient/caregiver outcomes.

### SCORING INCONSISTENCIES IN IMPLEMENTING THE STRUCTURED DELIRIUM ASSESSMENT IN A MULTICENTER RANDOMIZED CLINICAL TRIAL

M.C. Okafor[1], A.L. Gruber-Baldini[1], J.P. Brown[1], E. Barr[1], E. Marcantonio[2], *1. University of Maryland Baltimore, Baltimore, MD, 2. Division of General Medicine and Primary Care, Beth Israel Deaconess Medical Center, Brookline, Massachusetts*

Delirium, a clinically important condition, is often missed in routine care and requires standard assessment tools. The Structured Delirium Assessment (SDA), a 5-part tool for delirium assessment, uses responses from the Mini-Mental State Examination (MMSE), Digit Span, and Albert Delirium Symptom Interview (DSI), to score the Memorial Delirium Assessment Scale (MDAS) and Confusion Assessment Method Diagnostic Algorithm (CAMDA). The SDA has been used in single-site studies; here we present its first use in a multi-site study. We identified SDA scoring inconsistencies in a multicenter randomized clinical trial, the Transfusion Trigger Trial for Functional Outcomes in Cardiovascular Patients Undergoing Surgical Hip Fracture Repair, Cognitive Ancillary Study (FOCUS-CAS). FOCUS-CAS examined blood transfusion strategy effects on delirium(n=174 patients). Staff from 13 FOCUS-CAS clinical sites underwent initial training; their performance was periodically assessed during data collection. The SDA was administered to patients multiple times: pre-randomization, post-randomization/in-hospital and 31-45 days post-discharge; 543 SDAs were collected. Scoring inconsistencies pertaining to incorrect summing/not following instructions were observed across all 5 parts of the SDA. Such inconsistencies were most common for DSI item 22a-attentional deficits (30.8%) and MDAS item 5-maintain/shift attention (26.7%). The Digit Span and DSI-consciousness sub-sections had minimal inconsistencies (<1%). Findings suggest that scoring inconsistencies may be reduced by providing scoring sheets for items requiring cross-scale summing and through enhanced instructions on using DSI items to score MDAS. Integrating questions verifiable through cross-checks may assist in assuring data quality, particularly in multi-site studies where onsite performance evaluations may be infrequent.

### INFLUENTIAL VARIABLES ON EGO-INTEGRITY/ DEPRESSION OF THE ELDERLY

K. Choi[1], S. Chang[2], E. Kong[3], C. Kim[4], H. Kim[5], M. Cho[6], *1. Nursing, Chung-Ang University, Seoul, Republic of Korea, 2. Korea University, Seoul, Republic of Korea, 3. Jesus University, Jeonju, Republic of Korea, 4. Hallym University, Chuncheon, Republic of Korea, 5. Kongju National University, Kongju, Republic of Korea, 6. Dongeui University, Pusan, Republic of Korea*

Purpose : Erikson described the task of old age as balancing the search for integrity and wholeness with a sense of despair. In this study we explored the influencing variables on the ego-integrity and depression in late adulthood in Korean society. This study aimed to predict achieving integrity and falling into depression of the elderly in late adulthood. Methods : Data were collected from June to December, 2005. The subjects were 417 elderly living in community settings in Republic of Korea. Through upper 25% groups and lower 25% groups by score of ego-integrity/ depression scale, high and low rank ego-integrity groups and high and low rank depression group were identified. Eleven predictors (self esteem, spirituality, life satisfaction, social support, and activity as grandparent, parent, spouse, a friend, a relative, a member of groups, a person with a religion) were analyzed by logistic regression. Results : Major predicting factors of ego-integrity are self-esteem (P=.003), and activity as a member of groups (P=.01). On the other hand, major predicting factors of depression are self-esteem (P=0.007), and activity as a friend (P=0.04). Conclusion : Self esteem which might be influenced by reinterpretation of events and situations throughout the life span is the major factor in both achieving ego-integrity/ falling into depression. This study could contribute to identifying the major areas of nursing interventions in achieving ego-integrity/ falling into depression in Korean society. Key words: Ego-integrity, Depression, The elderly

### IMPACT OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE ON ANTIDEPRESSANT UTILIZATION IN DEPRESSED ELDERLY

J. Qian[1], L. Simoni-Wastila[1], I.H. Zuckerman[1], H. Yang[1], G.B. Rattinger[1], S.K. Dutcher[1], S.W. Lehmann[2], B. Stuart[1], *1. Peter Lamy Center on Drug Therapy and Aging, University of Maryland, Baltimore, Baltimore, Maryland, 2. Johns Hopkins University, Baltimore, Maryland*

Background: Chronic obstructive pulmonary disease (COPD) and depression are highly comorbid in older adults. Although antidepressant medications can improve clinical outcomes in COPD patients, little research has evaluated the influence of comorbid COPD on antidepressant utilization. Objectives: To assess the impact of comorbid COPD on antidepressant use and duration of treatment (DOT) in depressed Medicare eligibles. Methods: Using MarketScan Medicare Coordination of Benefits data from 2006-2007, we identified Medicare beneficiaries age ≥ 65 years diagnosed with major depression (n=27,066). Use of any antidepressant was defined by filling ≥ 1 antidepressant prescriptions during the study period. DOT was defined by days between receipt of first and last antidepressant over the two-year period. We used multivariate logistic regression to estimate antidepressant use and generalized linear model to estimate antidepressant DOT. Results: Of our depressed cohort, 16.8% had COPD. Relative to depressed-only beneficiaries, those with comorbid COPD had more comorbidities (7.6 vs. 5.5), longer hospitalization days (12.2 vs. 5.4), and more medications (11.0 vs. 8.0), including antidepressants (82.9% vs. 78.9%) (all p<0.0001). Average antidepressant DOT was shorter for depressed patients with COPD than those without (529 vs. 556 days, p<0.0001). Multivariate analyses revealed that individuals with comorbid COPD had 4% lower antidepressant use (p<0.0001) and 4% shorter DOT (p<0.0001). Conclusions: Findings suggest that comorbid COPD status affects depression treatment in the elderly by reducing antidepressant use and duration. Future research is needed to address the impact of depression management in clinical outcomes of older adults with COPD.

### THE BURDEN OF DEPRESSION ON THE QUALITY OF LIFE AMONG OLDER ADULTS WITH MEDICARE SUPPLEMENT INSURANCE

R.J. Ozminkowski[4], K. Hawkins[1], M. Bai[1], S. Musich[1], J. Unutzer[2], R.J. Migliori[4], C. Yeh[3], C. Hommer[4], *1. Ingenix, Ann Arbor, Michigan, 2. University of Washington Medical Center, Seattle, Washington, 3. AARP Services Inc., Washington, District of Columbia, 4. UnitedHealth Group Alliances, Ann Arbor, Michigan*

Objective: Estimate the burden of depression and comorbidities on quality of life (QoL) among members age 65 and older with AARP® Medicare Supplement (i.e., Medigap) Insurance underwritten by UnitedHealthcare (or UnitedHealthcare of New York, for residents there.) Study Design: Data were obtained from the Health Update Survey (HUS). The HUS contains questions on demographics, comorbid conditions, and the Veterans RAND 12-item health status instrument, which was derived from the Short Form 12-item instrument (the SF-12). The HUS was mailed to a random sample of 30,000 insureds from 10 states in 2008 and 2009. Survey respondents were divided into those with and without depression. Depression was measured based upon answers to survey questions which indicated problems with depression that occurred either just in the previous 12 months (i.e., “current depression,”) or for at least two years during one’s lifetime (“chronic depression”). Population Studied: Of the 11,867 respondents, 2,283 (19.2%) provided evidence of current depression and 590 (5.0 %) indicated problems with chronic depression. Principle Findings: After adjusting for demographic and health status differences via multiple regression analyses, those with current or chronic depression averaged significantly lower scores on every quality of life dimension. Depression’s largest impacts were on vitality, social functioning, and the ability to fulfill emotional roles. Every comorbidity significantly enhanced depression's negative impact on quality of life in at least one of the quality of life dimensions. Conclusions: Depression significantly reduces quality of life and its impact intensifies when chronic physical comorbidities exist.

### RISK FACTORS ASSOCIATED WITH DEPRESSIVE SYMPTOMS IN OLDER VETERANS IN THE VA HEALTH CARE SYSTEM

J. Park, *School of Social Work, Florida Atlantic University, Boca Raton, Florida*

The cross-sectional study described depressive symptoms in older veterans (≥65 years) with chronic pain and examined potential risk factors associated with depression in this population. A sample of 107 older veteran currently receiving health care services from the Baltimore Veterans Affairs Medical Center was recruited. Self-reported health status, physical disability, race, marital status, and social support were assessed. Descriptive statistics and ordinary least square [OLS] regression with simultaneous data entry were conducted to examine whether risk factors based on the literature review were associated with depression. The overall regression model was significant ($p < .0005$), $N = 107$, $F$ (5, 101), accounting for 28.1% of the variance in the dependent variable by the set of independent variables, R square = .281, Adjusted R square = .245. The study findings indicated that poor health status, being married, lower level of social support, and higher level of physical disability were significantly associated with higher level of depressive symptoms. Although the participants were enrolled in Veteran Health Care programs, there is limited coverage of treatment for their chronic diseases. Limiting such cover¬age could have a detrimental effect on older veterans who need intensive and comprehens¬ive medical services. In order to decrease health care utilization costs through reduction in admissions to hospitals, nursing homes, and other assisted living facilities due to the multiple chronic diseases, more research is needed to investigate the role of formal social support, change Medicare policy, and systematically help older adults to manage chronic disease and improve mental health.

### TRENDS IN DEPRESSIVE SYMPTOMS AND THE DETERMINANTS OF CHANGES AMONG TAIWANESE ELDERLY: A COHORT STUDY BETWEEN 1994-2004

H. Chiu[1], C. Chen[2], J. Mullan[3], D. Griffiths[3], I. Kreis[3], T. Lan[2], *1. Graduate Institute of Healthcare Administration, Kaohsiung Medical University, Kaohsiung, Taiwan, 2. National Health Research Institutes, Miaoli, Taiwan, 3. University of Wollongong, Wollongong, New South Wales, Australia*

This longitudinal study was conducted between 1994 and 2004 based on a community-dwelling elderly cohort in southern Taiwan. This study aims to examine trends in depressive symptoms of elderly people and the determinants associated with the changes, using a ten-year longitudinal data with six waves of cross-sectional data. The Short Psychiatric Evaluation Schedule (SPES) was used for collecting information on depressive symptoms. Socio-demographic factors, socioeconomic factors, living arrangements, health-related behaviors, chronic diseases, and disability were included as the predictors of depression symptoms. The significance of the differences between the trends of depressive symptoms was examined by using the generalized estimating equation (GEE) approach. The study showed great complexity in the development of depressive symptoms. It is worth noting that psychological components of depressive symptoms were more likely to increase over time. Being female, not married, living alone, with low socioeconomic status, negative life style, having chronic diseases, and ADL/IADL disabilities were significant predictors of depressive symptoms. This is the first study that has ever examined depressive symptoms in elderly population over a ten-year time span and found a persistently increasing trend of depressive symptoms. The present findings confirm that depressive symptoms in ageing population are complex and characterized by individual variations in socioeconomic resources, physical health and functioning. It seems that disability is of central significance of late life depression. Effort to slow down the increasing trends of depression in the elderly should target the risk factors associated with chronic diseases, disability, and persistent depressive symptoms.

### MULTIPLE PROGRAMS OF INTERGENERATIONAL REMINISCENCE FOR OLDER ADULTS AND THE YOUNG GENERATION

H. Matsuzawa[1], N. Miyamoto[1], Y. Tsuboyama[1], Y. Kurokawa[2], *1. KEISEIKAI Institute of Gerontology, Tokyo, Japan, 2. Sophia University, Tokyo, Japan*

As Japan faces aging of the population and low birthrates, the traditional extended family is rapidly decreasing with less interaction between older adults and the younger generation. From 2005 to 2009, intergenerational reminiscence programs were executed for the purpose of promoting mental health of elderly people and reducing prejudice against the elderly. Three programs were conducted: (1)Intergenerational reminiscence groups for older adults and the younger generation, (2)Workshops for training facilitators of intergenerational reminiscence programs, (3)Education about aging to university students to counter negative images of elderly people. The effect of each program was examined by questionnaires and interviews. Intergenerational reminiscence groups were held fifteen times in local communities. Through participating in groups and relating their individual experiences, older adults realized the value of their own lives and expressed positive feeling to the young generation. Workshops for training facilitators were held five times. In each session, a lecture by a professional psychologist was given, and participants mutually presented their practices of groups. Specific sessions of the intergenerational groups were recorded on DVD. The edited DVD was used as a tool for the educational programs. More than 320 university students watched the DVD. After watching DVD, they replied to questionnaires and reported their views about aging. Changes in views of aging, increased understanding of the diversity of older adults and recognition of the wisdom of old people were reported by the students.

### SHORT-TERM ANXIETY OUTCOMES AND CORRELATES IN OLDER ADULT CARE MANAGEMENT CLIENTS

A. Simning[1], Y. Conwell[2], *1. University of Rochester School of Medicine and Dentistry, Department of Community and Preventive Medicine, Rochester, New York, 2. University of Rochester School of Medicine and Dentistry, Department of Psychiatry, Rochester, New York*

Background: Although anxiety symptoms are common among older adults receiving in-home care management services, we know little about how anxiety changes following care management intervention. This study aims to characterize the change in anxiety as well as the correlates associated with improving anxiety in care management clients. Methods: The study consists of a stratified sample of clients aged 60 and older receiving in-home care management services from a social services agency; stratification was based on depression scores. The GAD-7 assessed anxiety severity in research interviews performed at baseline and one-month follow-up. Results: The 86 participants had a mean age of 72 years; 77% were female, 69% white, and 69% unmarried. One month following the care management assessment, many clients were less anxious. Of those suffering from at least mild anxiety, 46% improved to a less severe symptom class and 44% remained unchanged. Among all clients, 14% worsened to a more severe anxiety severity class. Clients with any improvement in anxiety symptoms constituted a more functionally impaired and socioeconomically vulnerable group at baseline than those who did not improve. Conclusions: There is modest improvement in anxiety among care management clients one month following an in-home assessment, especially in those who are functionally impaired and socioeconomically disadvantaged. The care management intervention is multifaceted and we do not know which components are most effective in reducing distress. Anxiety did not improve for many clients, however, and further research is necessary to better understand how to improve mental health outcomes in care management clients.

### PHYSICAL PERFORMANCE, EXERCISE, AND MAGNETIC RESONANCE SPECTROSCOPY OF THE MEDIAL TEMPORAL LOBE IN OLDER ADULTS WITH MILD COGNITIVE IMPAIRMENT

E.L. McGough[1], R.G. Logsdon[1], K.E. Weaver[2,3], T.R. Richards[2,3], S.M. McCurry[1], L. Teri[1], *1. School of Nursing, University of Washington, Seattle, Washington, 2. Integrated Brain Imaging Center, University of Washington, Seattle, Washington, 3. Department of Radiology, University of Washington, Seattle, Washington*

BACKGROUND: Older adults with mild cognitive impairment (MCI) have a higher risk for Alzheimer's disease (AD), especially those with lower physical performance and exercise levels. At present, little is known about the neurochemical correlates of MCI and physical performance or MCI and exercise. This study examined associations between physical performance, exercise levels, and MTL metabolites in older adults with MCI. METHODS: The Short Physical Performance Battery (SPPB), minutes of exercise in the past 7 days (self-report), and 1H magnetic resonance spectroscopy (MRS; at 3T) data were collected from 15 individuals with MCI (mean age= 85.4, SD 4.5), during baseline assessments of a larger randomized trial of an exercise intervention. For MRS, short echo acquisitions were collected from a hippocampus voxel and an occipital lobe voxel (control). Absolute concentrations of MTL metabolites (N-acetyl aspartate, creatine, choline, and myoinositol) were quantified. Analyses included Pearson's coefficients for SPPB in relation to MTL metabolites, and an independent t-test (95% CI) to examine differences in MTL metabolites by high vs. low exercise. RESULTS: Correlations between SPPB and MTL metabolites, choline ($r = -0.766$, $p = .001$) and creatine ($r = -0.627$, $p = .016$) were significant after adjusting for age. The mean concentrations of choline ($p=.022$) and myoinositol ($p=.019$) were significantly greater with low exercise. CONCLUSIONS: Poorer physical performance and low exercise were associated with elevated MTL metabolites typically involved in neurodegenerative processes. Further studies are needed to examine the role of MTL metabolites and their response to exercise interventions in individuals with MCI.

## SESSION 380 (SYMPOSIUM)

### MEASURING AND UNDERSTANDING RESERVE AND RESILIANCE

Chair: *T.T. Perls, Medicine & Geriatrics, Boston University School of Medicine, Boston, Massachusetts*
Discussant: *T. Harris, National Institute on Aging, Bethesda, Maryland*

The compression of morbidity and disablity towards the end of life has tremendous implications in terms of effecting healthy aging. Study of these phenomena have been hampered by inconsistent measures. To address measuring issues, the application of Item Response Theory and accurate estimates of latent traits will be discussed. Results from the 20 year longituninal study of ~2,300 60 year old college alumni reveal important associations between obesity, inactivity and smoking and disability. In the 18 year study of 8,600 septuagenarians in the Health and Retirement Study, living longer is associated with surviving to late ages without diseases and disabilities. Persons with higher socioeconomic status are more likely to survive without disease and disability and thus lead both longer lives and longer healthy lives. Similar findings are discussed using data from the Age, Gene/Environment-Reykjavik Study and the Health, Aging, and Body Composition Study. In the New England Centenarian Study, supercentenarians (age 110+) had lower prevalence rates and a higher age of onset for almost all age-associated illnesses reported compared to younger centenarians (age 100-104). Both centenarian groups had a marked delay in disability. With regard specifically to cognitive impairment, epidemiologic evidence suggests that cognitive reserve can be enhanced through life experiences at any age, therefore supporting the idea that non-pharmaceutical interventions might slow or prevent the cognitive effects of aging and dementia. Surviving to very old age is a matter of resilience and reserve earlier in old age.

### MEASURING AND MONITORING TRENDS IN MORBIDITY USING ITEM RESPONSE THEORY (IRT)

J.F. Fries, *Standford University, Palo Alto, California*

Background: Trends in the compression or extension of morbidity are central to the longitudinal study of human aging, yet validity is threatened when outcomes are inconsistently defined and inaccurately measured. Methods: Item Response Theory (IRT) approaches can estimate a latent trait much more accurately than before. We studied 2,327 college alumni annually from age 68 years for 20 years. Results: Disability increased over time for all groups, 200 % as rapidly in the high risk group (HR) as in the low (LR) (0.3 vs 0.6 units) ($p<0.001$). Mortality rates were increased 150 % from 247 to 384 in HR ($p<0.001$). Conclusions: Obesity, inactivity, and smoking are associated with increased disability and mortality in later life. Disability is postponed more than mortality, supporting compression of disability, and by inference, morbidity. Precise definition and measurement of endpoints is essential to strengthen results.

### COGNITIVE RESERVE AND AGING

Y. Stern, *Columbia University, New York, New York*

The concept of reserve emerged from observations of a disjunction between the degree of brain changes or pathology and the clinical manifestation of those changes. Epidemiologic studies indicate that life experiences including educational and occupational exposure and leisure activities are associated with a slower rate of cognitive decline in normal aging and reduced risk of developing dementia. Two types of reserve are possible. Brain reserve applies to anatomic differences in the brain that may allow some individuals to cope better with brain changes. Cognitive reserve postulates that individual differences in the cognitive processes underlying task performance allow some people to cope better than others. Because epidemiologic evidence suggests that cognitive reserve can be enhanced through life experiences at any age, this concept supports the idea that nonpharmaceutical interventions might slow or prevent the cognitive effects of aging and dementia.

### COMPRESSION OF MORBIDITY AND DISABILITY AMONGST CENTENARIANS AND SUPERCENTENARIANS

S.L. Andersen[1], T.T. Perls[1], P. Sebastiani[2], A. Reid[1], M. Frederick[1], L. Feldman[1], *1. Medicine & Geriatrics, Boston University School of Medicine, Boston, Massachusetts, 2. Boston University School of Public Health, Boston, Massachusetts*

Background: Given that they live at the limits of human life span, centenarians and supercentenarians are an important group to study for the phenomenon of compression of disability and morbidity. Methods: We studied 105 supercentenarians (age 110+ years) to determine if our observations of younger centenarians hold true for this group. Results: Supercentenarians had lower prevalence rates and a higher age of onset for almost all age-associated illnesses reported compared to centenarians (age 100-104). Most notably, 28% of supercentenarian had cardiovascular disease with a mean age of onset of 98 compared to 47% of centenarians with a mean age of onset of 88. Comparing ADLs, mean Barthel Index score for supercentenarians dropped below functional independence at age 106 compared to 100 for centenarians indicating a delay of 6 years in the onset of disability in supercentenarians. Conclusion: Among supercentenarians, exceptional longevity is associated with increased health span.

### SURVIVAL, RESILIENCE AND RESERVE IN A NATIONAL POPULATION

E. Crimmins, H. Beltran-Sanchez, J.A. Ailshire*, University Southern California, Los Angeles, California*

Background: We examined subjects in the original AHEAD cohort of the Health and Retirement Study, a representative sample of Americans 70 and over who have now been interviewed 10 times over 18 years. We compare survival, cognitive and physical functioning and indicators of risk by age at death to see how cohorts who die after 100 compare to cohorts who die in their 80s and 90s. Methods: 8,600 people according to the age at death or the potential age at death Results. The age at onset of major disease, risk factors, and functioning loss is related to the age at which people die. Living longer does not mean living sicker longer. Conclusion: Living longer is associated with surviving to late ages without diseases and disabilities. Persons with higher socioeconomic status are more likely to survive without disease and disability and thus lead both longer lives and longer healthy lives.

### RESILIENCE AND RESERVE IN OLD AGE: FIXED OR FLUID?

T. Harris*, National Institute on Aging, Bethesda, Maryland*

Resilience and reserve (RNR) are thought to be critical to maintenance of disability free survival in old age. RNR may be determined by factors including genetics, in utero exposures, social class, optimal health behaviors, health, and personality. In general, RNR reflects what is brought into old age from earlier life. Clinical trials in older persons, even with molecular outcomes, suggest that some of these factors are malleable and that reserve may be added even in the very old. Using data from the Age, Gene/Environment-Reykjavik Study and the Health, Aging, and Body Composition Study, these factors will be highlighted and the discussion augmented with data from clinical trials in older persons.

## SESSION 385 (PAPER)

## RESEARCH METHODS: LONGITUDINAL DATABASES AND TOOL DEVELOPMENT

### DEVELOPMENT AND VALIDATION OF A SHORT FORM OF THE GERIATRIC ANXIETY INVENTORY

G. Byrne[1,3], N.A. Pachana[2]*, 1. School of Medicine, University of Queensland, Brisbane, Queensland, Australia, 2. School of Psychology, University of Queensland, Brisbane, Queensland, Australia, 3. Royal Brisbane & Women's Hospital, Brisbane, Queensland, Australia*

While several instruments now exist to measure anxiety in older people, there is a need for a very brief self-report scale to measure anxiety symptoms in epidemiological surveys and in busy general medical settings. Accordingly, we undertook the development of such a scale, based on our Geriatric Anxiety Inventory (GAI). We developed a 5-item measure, which we have called the Geriatric Anxiety Inventory – Short Form (GAI-SF), using a combination of psychometric and pragmatic considerations. We eschewed the use of somatic items to avoid confounding with the general medical conditions that occur commonly in older people. We retained a dichotomous response scale (Agree/Disagree) to maximize accessibility. We tested the GAI-SF against MINI-V/DSM-IV diagnoses of Generalized Anxiety Disorder using receiver operating characteristic (ROC) analyses in a cross-sectional study among randomly selected, community-residing, older women (N = 284; Mean age 72.2 years). Internal consistency was high (Kuder-Richardson coefficient = 0.81) and concurrent validity against the Spielberger State-Trait Anxiety Inventory was good ($r = 0.48$, $p < 0.001$). We found that the optimal threshold for the detection of GAD in this community sample was a score of three or more out of a possible score of five. At this cut-point, sensitivity was 75%, specificity was 87%, and 86% of participants were correctly classified. The area under the ROC curve was 0.80. GAI-SF score was not related to age, MMSE score, level of education or perceived income adequacy. We recommend the GAI-SF for use as a brief screening instrument for anxiety in older people.

### RACIAL DIFFERENCE IN AGING: THE CASE OF CARDIOVASCULAR DISEASE

A. Chattopadhyay*, University of California at San Francisco, San Francisco, California*

The age pattern of cardiovascular disease (CVD) between the races has implications for studies of racial difference in aging that is not discernable with traditional age adjusted analysis. Using data from NHANES and the CDC WONDER files, this paper shows that racial differences in CVD prevalence and mortality varies markedly by age, with little or no differences among the elderly but the large disparities in younger ages. Black-White differences in age-sex specific prevalence rates were tested using a logistic model which controlled for clinical conditions, socioeconomic status and health care access. Mortality differences were examined using standard demographic methods. CVD prevalence was 2.4 ($p<.01$) times higher in blacks than whites in the 35-44 age group, but the differentials declined in higher age groups until it vanished for those over age 65. Clinical and socioeconomic factors account for some, but not all, of the differences between blacks and whites at each age. A similar age pattern was also seen for CVD mortality. Thirty-five to forty four year old black persons had 2.5 higher mortality compared to whites of the same age-group, where as elderly blacks had only. 9% excess mortality. Over a quarter (26%) of all CVD deaths occur before age 65 among blacks, while only 15% of all such deaths occur among whites. The similarity in the age pattern of disease rates with mortality rates suggests differences in disease severity and provides evidence for the heterogeneity of the aging processes between the races

### MULTIMORBIDITY AND HEALTH OUTCOMES: A REPORT FROM THE HEALTH AND RETIREMENT STUDY

S. Koroukian[1], D.F. Warner[1], C. Owusu[1], C.W. Given[2]*, 1. Epidemiology and Biostatistics, Case Western Reserve University, Cleveland, Ohio, 2. Michigan State University, East Lansing, Michigan*

Introduction: The effects of multimorbidity on health status /decline have not been fully explored. We report our findings on these effects from our analysis of self-reported data from the 2004-2006 Health and Retirement Study. Methods: Multimorbidity was characterized by the occurrence and co-occurrence of comorbidities (COM), functional limitations (FL), and geriatric syndromes (GS). Accordingly, we grouped respondents in the following clinical categories: CC0: none of COM, FL, or GS; CC1: occurrence – but no co-occurrence – of COM, FL, or GS; CC2: co-occurrence of any two of COM, FL, and GS; and CC3: co-occurrence of all three of COM, FL, and GS. Our outcome measures included fair/poor health status and 2-year health decline from excellent, very good, or good to fair/poor health, or decline from fair to poor health. We used multivariable logistic regression analysis to evaluate the association between multimorbidity and each of the outcomes, adjusting for clinical and individual attributes. Results: Our study population included a U.S. representative sample of 13,589 individuals age >= 50 years. Fair/poor health and decline were significantly associated with multimorbidity. Compared to CC0, and respectively for each of fair/poor health and decline, the adjusted odds ratios and 95% confidence Interval were 2.78 (2.14, 3.61) and 2.10(1.54, 2.87) for CC1; 6.25 (4.84, 8.07) and 3.28 (2.42, 4.45) for CC2; and 26.3 (20.3, 34.1) and 5.17 (3.80, 7.03) for CC3. Conclusions: Multimorbidity is strongly and significantly associated with fair/poor health status and decline. These findings carry important implications in clinical practice and outcomes research.

### EFFECTS OF LONGITUDINAL STUDY PARTICIPATION ON PHYSICAL AND COGNITIVE FUNCTION IN OLDER ADULTS

M. Hackney[1], K. Hawley[1], S. Whitbourne[3], L.P. Nadel[1], A. Spiro[3], K. Echt[1,2], *1. Atlanta VA Rehabilitation Research & Development Center of Excellence in Aging Veterans with Vision Loss, Decatur, Georgia, 2. Emory University School of Medicine Division of Geriatric Medicine and Gerontology, Atlanta, Georgia, 3. VAMC Boston, Boston, Massachusetts*

Longitudinal study participants are often rigorously screened at enrollment and may become increasingly select over time, limiting generalizability. The longitudinal VA Normative Aging Study (NAS) began in 1963 with initially healthy men. The study evaluated cross-sectional physical and cognitive performance data collected from a sample of NAS men (n=55; 77±5 years) compared to a sample of older adults (OA; n=40; 74±6 years). Participants completed demographic, quality of life (SF-36), physical function (grip strength, 30-Second Chair Stand, 8 foot Up&Go, gait speed) and cognition measures (Verbal Ability, Memory, Reasoning). NAS participants did not differ in educational level from OAs, but were older, had worse vision, took fewer medications, and more reported good or better health (85.4% vs. 80.0%; p's<0.01). NAS participants did not differ from OA in gait speed, but had greater grip strength (NAS: 46.9±22kg, vs. OA: 35.8±9.1kg), better scores on the Chair Stand (NAS: 12.1±3.3 rises vs. OA: 9.4±3.5 rises) (p's< 0.001), and needed less time to complete the Up&Go (NAS: 7.6±1.7 sec vs. OA: 8.6±2.5 sec; p = 0.015) than OA. NAS also had significantly higher MMSE (NAS: 27.7±1.4 vs. OA: 26.5±2.6) and verbal ability scores (NAS: 34.5±3.5 vs. OA: 30.4±7.9; p< 0.01). NAS participants were significantly older than OA, but demonstrated better physical and cognitive function. Also, better physical performances were associated with higher cognitive performances (r's= 0.24-0.38). Further investigation must determine whether superior NAS performances stem from effects of longitudinal health observation or from protective effects engendered by superior physical health and fitness at enrollment.

## SESSION 390 (SYMPOSIUM)

### THE BERLIN AGING STUDY II (BASE II)

Chair: *E. Steinhagen-Thiessen, Dep. on geriatric research, Charite University Medicine, Berlin, Germany*
Co-Chair: *J. Smith, Macquarie University, Ann Arbor, Michigan*
Discussant: *J.D. Walston, Johns Hopkins Geriatric department, Baltimore, Maryland*

This symposium presents the structure, goals and first results of the Berlin Aging Study II (BASE-II). BASE-II is a collaborative project between the Max-Planck-Institute for Human Development, the Charité Geriatric Department, the Max-Planck-Institute for Molecular Genetics, and the German Socio-Economic Panel Study (SOEP). Our multidisciplinary study is examining 2200 subjects from two age groups (20-30 and 60-70 years) recruited from all over Berlin. BASE-II aims to characterize, compare and follow-up medical, cognitive, neuropsychologic, genetic, social and economic aspects across both age groups, with special emphasis on the elderly. A major goal is the identification of biomarkers that will help to predict diseases at an early stage and to facilitate preventive and/or early therapeutic interventions. To date, 2200 probands were tested for cognitive function, 1300 were interviewed by means of the SOEP protocol, 1330 were assessed by genome-wide screening, and 500 underwent extensive medical and neuropsychologic testing (e.g. detailed medical history and examination, extensive laboratory tests, neuropsychologic assessment, motoric function, gait analysis, electronic tapping, grooved pegboard test, HU-Motion belt, bone density, bioimpedance analyses, vision, hearing, cardiac function). In addition to introducing the structure and selectivity of the BASE-II sample, we present data on factors associated with life satisfaction, the relation between vitamin D levels and frailty syndrome, as well as on the comparison of methods detecting arrhythmic cardiac events and mild cognitive impairment. Furthermore, we present first results from our genome-wide association analyses for which we correlated medical and cognitive phenotypes with known genetic modifiers of dementia and lipid metabolism.

### BASE-II AS A STUDY RELATED TO SOEP (GERMAN SOCIO-ECONOMIC PANEL STUDY)

G.G. Wagner[2], L. Bertram[3], G. Papenberg[2], E. Steinhagen-Thiessen[1], J.K. Wolff[2], U. Lindenberger[2], *1. Dep. on geriatric research, Charite University Medicine, Berlin, Germany, 2. MPI for Human Development, Berlin, Germany, 3. MPI for Molecular Genetics, Berlin, Germany*

It is an almost unique feature of BASE-II that this city-based study is embedded into a nationwide longitudinal study, the German Socio-Economic Panel Study (SOEP). This feature enables to analyze the representativeness of BASE-II in comparison to the random sample of SOEP which is representative for the population in Germany. As SOEP covers more than 10,000 private households with roughly 20,000 adult respondents it includes a sub-sample of about 350 households in Berlin which is large enough to allow comparisons with the participants of BASE-II. We first present analyses of the prepresentativeness of BASE-II compared to Berlin followed by a comparison to the entire population in Germany.

### INSUFFICIENCY AND DEFICIENCY OF VITAMIN D: IMPACT ON THE DEVELOPMENT OF THE FRAILTY SYNDROME IN OLDER ADULTS OF BASE-II

D. Spira, K. Külbel, V. Moskiou, E. Steinhagen, N. El-Zidy-Ibrahim, H.K. Berthold, E. Steinhagen-Thiessen, *Dep. on geriatric research, Charite University Medicine, Berlin, Germany*

The Frailty Syndrome is a multidimensional syndrome characterized by loss of diverse functional abilities and subsequent heightened morbidity and mortality. Vitamin D insufficiency - highly prevalent in older adults - is also associated with several of the conditions that may contribute to the Frailty Syndrome. In a sample of 300 persons aged 60 years or older participating in the Berlin Aging Study Part II we measured levels of 25(OH) Vitamin D3 in conjunction with an extensive assessment of clinical data including laboratory tests, geriatric assessment of physical performance and mental function, bone density and body composition via DEXA scan, as well as estimation of nutritional status and physical activity levels gathered by questionnaire. Of our participants 64% have demonstrated evidence of inadequate vitamin D serum levels (< 50 nmol/l). We will present data suggesting possible pathological mechanisms linking low Vitamin D levels with frail health status.

### BASE-II: STANDARD VERSUS 2-HOUR ELECTROCARDIOGRAPHY FOR PREDICTING ARRHYTHMIAS IN THE ELDERLY

N. El-Zidy-Ibrahim, A. Töpper, K. Scileppi, D. Spira, V. Moskiou, S. Kubenz, W. Haverkamp, E. Steinhagen-Thiessen, *Dep. on geriatric research, Charite University Medicine, Berlin, Germany*

Transient arrhythmia cannot always be detected on a resting electrocardiogram (ECG), for which the established reference examination is the 24-hour ECG. A timesaving diagnostic alternative would be of clinical significance. To determine the comparative sensitivity of the two techniques for the detection of cardiac arrhythmia in asymptomatic patients 300 participants in the Berlin Aging Study II received both a 2-hour and a standard 12-lead resting ECG. Results were evaluated for determination of heart rate variability, rhythm and arrhythmia, ectopic events and conduction disturbances. Evaluation of tracings was performed utilizing computer-assisted algorithmic analysis to search for occult episodic atrial fibrillation and predictive indications of atrial fibrillation. The latter will be evaluated over the next two years. Extending the observational time frame of ECG analysis to 2 hours may afford a sufficient database for computerized algorithms to identify patients at higher risk for arrhythmic or conduction disturbances.

### BASE-II: SENSITIVITY OF SCREENING TESTS TO DETECT MILD COGNITIVE IMPAIRMENT & EARLY DEMENTIA

N. Bucholtz, G. Lämmler, K. Hoffmann, D. Meierkord-Palme, S. Kubenz, E. Steinhagen-Thiessen, *Dep. on geriatric research, Charite University Medicine, Berlin, Germany*

Neuropsychological screening instruments are widely utilized in the identification of patients with dementia. Sensitivity is low, however, for patients with mild cognitive impairment (MCI) or early dementia. One limitation is that test results are interpreted without reference to variables such as age, sex and education. The aim of this study is to examine the potential for enhanced diagnostic accuracy of standard screening tests by the incorporation of these demographic data. Five hundred participants of the BASE-II study were assessed using the standard Mini Mental Status Examination and Clock Completion Test, as well as the German-based DemTect. A diagnosis of MCI or dementia was established according to the criteria contained in the neuropsychological test battery of the Consortium to Establish a Registry for Alzheimer's Disease. Based upon preliminary data we report the effect upon screening instrument accuracy when adjusted for covariates and the implications for clinical practice.

### GENOME-WIDE SCREENING OF THE BASE II POPULATION: FIRST RESULTS

L. Bertram[1], W. Nietfeld[1], S. Li[2], L. Bäckman[4], A. Trovato[3], E. Steinhagen-Thiessen[3], U. Lindenberger[2], *1. Max-Planck Institute for Molecular Genetics, Berlin, Germany, 2. Max-Planck Institute for Human Development, Berlin, Germany, 3. Charite University Medicine, Berlin, Germany, 4. Karolinska Institute, Stockholm, Sweden*

One major aim of the BASE II study is to investigate the impact of genetic factors on cognitive, socio-economic, and medical phenotypes assessed during the examination of study participants. To this end, we have recently completed the genotyping phase of a genome-wide association study (GWAS) using the Affymetrix Human SNP Array 6.0 for a subset of the BASE II participants (n=1,330). This array covers over 1.8 million genetic markers to investigate both single-nucleotide polymorphisms (SNPs) and copy number variants (CNVs). Here, we will present the results of first analyses using the GWAS dataset focusing on genes known to be involved in dementia, memory, and lipid metabolism. These findings will be compared to analyses correlating the same traits with the ε2/3/4 haplotype in the APOE gene, a well-established genetic modifier of cognitive performance and cholesterol homeostasis, and the strongest known risk factor for Alzheimer's disease.

## SESSION 395 (SYMPOSIUM)

### ESPO PRESIDENTIAL SYMPOSIUM: THE STRUGGLE BETWEEN PERSONAL & PROFESSIONAL IDENTITY: TRANSITIONING FROM STUDENT TO EMERGING SCHOLAR AND PROFESSIONAL

Chair: *N. Leland, Community Health Center for Gerontology and Health Care Research, Brown University, Providence, Rhode Island*

The interplay between personal and professional identity is a common concern among Emerging Scholar and Professional Organization (ESPO) members. Last year, ESPO and GSA jointly conducted a survey to identify issues and concerns related to career and family planning among ESPO members. One of the top three concerns identified by survey respondents was their ability to maintain a balance between personal life and career. This struggle for balance between the personal and professional identity incorporates the push and pull of an individual's self-definition, values, roles, routines, and personal and professional expectations. The objective of this ESPO Presidential Symposium is to facilitate a discussion about the struggle for this personal-professional balance, highlighting issues such as: starting a family, parenting, chronic illness/ disability and career development, mentorship, and seeking international job opportunities. This symposium aims to achieve these objectives through facilitated roundtable discussions on these identified topics.

### BALANCING PROFESSIONAL AND PERSONAL IDENTITIES: LGBT PERSPECTIVES

G. Harris, *Fielding Graduate University, Santa Barbara, California*

The proposed discussion will center on issues faced by emerging LGBT scholars and professionals. Specifically, the discussion will focus on the interplay between the personal and professional self, mentors and allies, and bias and discrimination in education, training, and work environments. We will discuss integration of the personal and professional selves, as well as the significance of internally consistent self-concepts in the above-mentioned environments. Particular interest will be on the balance between caring for self and others when working with older adults. Additional topics will include the effects of discrimination in these environments, appropriate ways to deal with discrimination, and the benefits of mentors and allies.

### CAREER DEVELOPMENT AND DISABILITIES

K.J. Johnson, *Gerontology, University of Massachusetts Boston, Boston, Massachusetts*

Striking an equilibrium between work and personal life is an ongoing challenge for most emerging professionals, but for those managing a chronic illness or disability, finding a balance between personal time and professional activities—research, teaching, and professional service—can be particularly daunting. Adding to this challenge is the lack of mentors serving as successful examples of developing and managing a professional identity while living with a disability or illness or while caring for an adult with such a condition. Fortunately, strategies exist that can help, such as prioritizing tasks and adjusting expectations, new technologies, and developing and promoting a focused professional identity. Most importantly, fellow emerging scholars who face similar time constraints and work-life issues surrounding their own or a loved one's disability or illness can bring their difficulties, ideas, and coping strategies to this roundtable discussion.

### CROSSING THE BORDER: CONSIDERATIONS FOR AN INTERNATIONAL CAREER

K. Fitzgerald, *Center for Gerontology, University of Zurich, Zurich, Switzerland*

Does working in Europe sound glamorous? Or working in South America sound challenging? Working abroad can bring about visions of excitement and adventure. Unfortunately if you are considering a job abroad, you must remember reality. There are challenges to adjusting to new cultures, accessibility to family back home, and before all of this, determining whether your degree is recognized and accepted in the country you are considering employment. Searching and applying for jobs abroad can be difficult. You can simplify this process by doing things such as developing your international network. This round table will discuss the questions you must consider as you determine whether you will work abroad, how you will begin searching for a job, and how you will make the move. Although making the decision to work abroad may sound like a daunting task, the rewards gained from working in a foreign country can be extremely worthwhile.

### BALANCING A GERONTOLOGICAL CAREER AND A FAMILY SUCCESSFULLY

C. Brown, *Seasons of Life, LLC, Parker, Colorado*

Gerontologists, either as a student or an emerging professional have concerns of starting a family and balancing a career as indicated by a recent survey conducted by ESPO and GSA. For the majority of respondents without children, career development has an influence on family planning. Many individuals desire to start a family; however, it is perceived that moderate disruption to ones academic or professional development is likely to arise. Respondents, who are parents, are aware that perfect timing to start a family is not likely. However, balancing parenting and a career can be achieved well. This may result in planning a career around a family instead of planning a family around a career. In addition, maintenance between family and a career may be enhanced by employer support through maternity/paternity leave and on-site day care facilities. This discussion will convey strategies to ESPO members for successful career and family management.

### MENTORING AND THE NON-TRADITIONAL STUDENT

W.E. Palmer, *Allied Health Sciences, The University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

In seeking mentors, non-traditional students and emerging scholars are challenged to get past superficial externals and discover the individual qualities that potential mentors possess. As non-traditional students we are sensitive to our "otherness", often justifiably, but we must beware our preconceived notions of the "type of person" we should seek as a mentor. As an older student I initially sought the advice of the older professors in my program and received excellent mentoring, yet I have also sought out and received excellent mentoring from junior faculty members young enough to be my children. Although my age defined my 'otherness', race, gender, sexual orientation, disability, ethnicity, national origin, or something else, may be your 'otherness'. This roundtable discussion is an opportunity to explore the role of "otherness" in finding and building mentor-mentee relationships.

## SESSION 400 (SYMPOSIUM)

### ACTIVITY ENGAGEMENT IN LATER LIFE: CONCEPTUAL AND MEASUREMENT ADVANCES

Chair: *N. Morrow-Howell, Washington University, St. Louis, Missouri*
Discussant: *M. Pitt-Catsouphes, Sloan Center on Aging & Work, Boston College, Boston, Massachusetts*

Engagement in activity has been central to theoretical discussions and empirical analysis of well-being in later life. Despite its important theoretical role, there has not been attention to the conceptualizing and measuring activity engagement. In general, researchers collect information about what activities older adults engage in and for how much time. They fail to capture more subjective realities of activity participation, like the extent of choice or positive feelings toward the activity. Further, researchers target a single activity, like physical activity, volunteering, or caregiving, ignoring the reality that older adults engage in multiple activities at any one time. In this session, we will present conceptual advances in the study of activity engagement and provide empirical findings to guide these theoretical developments. We will first discuss how to assess the extent to which employees, volunteers, and caregivers perceive choice of activity involvement, the quality of the connection and psychological importance of the activity. Data from a new measurement tool are presented. We then compare two existing measures of employee engagement, including divergence in results that depend on the instrument used. Finally, we will present a rationale and approach to consolidating discrete activity items into two concepts: activity domains and engagement patterns, and data from the HRS are used to demonstrate the utility of these concepts. A discussant will reflect on the contribution of this work toward knowledge development about activity engagement that may be most beneficial for older adults, families, and society.

### ASSESSING INVOLVEMENT VS. ENGAGEMENT IN FOUR ACTIVITIES OF LATER LIFE

J. James, E. Besen, C. Matz-Costa, M. Pitt-Catsouphes, *Boston College, Sloan Center on Aging and Work, Chestnut Hill, Massachusetts*

Previous research assessing the benefits of older adult activities typically asks about involvement, i.e., what activities older adults are doing, and perhaps the level of activity. While valuable, such research tells us little about what the involvement means to participants or how energetic they are about their participation. Although many researchers use the terms involved and engaged interchangeably, we argue that there are important distinctions. Involvement has to do with participation in the activity, whether by choice or by perceived demand, while engagement connotes the quality of the connection or the feelings that occur when someone attaches psychological importance to the activity. A validated measure of work engagement (Schaufeli, et al., 2002) was used to construct measures of engagement with volunteer, caregiving, and educational activities for the Life & Times in an Aging Society Survey. Preliminary analyses reveal that engagement predicts well-being outcomes over and above involvement.

### THE MEASUREMENT OF EMPLOYEE ENGAGEMENT

C. Matz-Costa, J. James, E. Besen, *Boston College, Sloan Center on Aging & Work, Chestnut Hill, Massachusetts*

Employers recognize the importance of efforts to keep employees of all ages engaged in their work. There has, however, been much debate about the measurement of employee engagement. A variety of competing and inconsistent interpretations of engagement have proliferated in the academic and practitioner literatures. As a result, it has been very difficult to form an agreed-upon definition and to synthesize data across studies. As one step toward progress, data were collected using two different measures of engagement (the Utrecht Work Engagement Scale and a vendor-based measure) in the Age & Generations Study (N=1,800). Analyses revealed differences in these measures of engagement by age group, such that, among employees under age 55, engagement increased with age, however among those age 55 or older, the patterns for the two measures diverged. Findings will be discussed in terms of the strengths and weaknesses of each measurement approach.

### CONSOLIDATING ACTIVITY ITEMS INTO ACTIVITY DOMAINS AND ENGAGEMENT PATTERNS

M. Putnam[1], N. Morrow-Howell[2], M. Inoue[3], J.C. Greenfield[4], *1. School of Social Work, Simmons College, Boston, Massachusetts, 2. Washington University in St. Louis, St. Louis, Missouri, 3. Boston College, Boston, Massachusetts, 4. Washington University in St. Louis, St. Louis, Missouri*

Modeling engagement by older adults in multiple activities at one time is stymied by the lack of composite measures. This limits theoretical development and empirical evaluation of predictors (e.g. health, prior engagement) and outcomes (e.g. life satisfaction) of activity participation. We tested two approaches to empirical consolidation of activity measures using the Health and Retirement Study's 2007 Activity Supplement. A variable-centered approach (exploratory factor analysis), identified 7 distinct activity domain factors including household chores, outdoor activities/hobbies, and social/relationship development and maintenance. Using a person-centered approach (latent class analysis), we identified 4 distinct groups across the 7 EFA produced domains. Three groups segmented by activity level across most domains, supporting conceptual distinctions in involvement versus engagement. The fourth group was low on all activities except work suggesting its dominance for some adults in old age. EFA and LCA findings will be discussed regarding their validity and usability as composite measures.

## SESSION 405 (SYMPOSIUM)

### CHANGES OVER TIME IN ASSISTED LIVING SERVICES AND MODELS OF CARE

Chair: *D.L. White, Portland State University, Hillsboro, Oregon*
Discussant: *S. Zimmerman, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

When assisted living (AL) residences emerged as a popular form of long-term care for older persons in the late 1980s, they were usually described as operating under a "social model" of care that deliberately sought to distance themselves from the "medical model" associated with nursing homes and hospitals. Over time, however, these distinctions have blurred. The result is a growing recognition of the need for new models of AL that more fully address the complex care needs of aging consumers while continuing to emphasize the core values of AL (e.g., privacy, dignity, choice). The papers in this symposium present research on recent and emerging models of care within AL. Papers address: 1) An overview of state policies is provided, including recent trends in defining and clarifying the use of person-centered and person-directed models of care and the role of nurses, physicians, and hospice care in AL. 2) The growing emphasis on person-directed care in delivery of long-term care services, highlighting research specific to AL. 3) The integrative role of nurses in AL, including care management, staff education, systems development, and interpersonal communication. 4) Implications of a recent national survey of physician involvement in AL residences for new physician roles and models of practice in AL. 5) Resident and family experiences with hospice care within AL residences and ways that hospice fills a gap in AL services, forestalling discharge at the end of life. Individualizing a comprehensive array of support services for AL consumers is a common thread throughout all papers.

### THE STATUS OF PERSON-CENTERED CARE POLICIES AND PRACTICES IN ASSISTED LIVING

K. Love[2], P. Carder[1], *1. Institute on Aging, Portland State University, Portland, Oregon, 2. Center for Excellence in Assisted Living, Falls Church, Virginia*

This paper describes what is currently known about state policies related to person-centered care (PCC) in assisted living (AL) residences. This overview is based on interviews with 38 long-term care experts (including researchers, providers, and policy makers), literature review, and regulatory review. Only a small number of states currently use person-centered care language, though some leaders in the AL industry have begun to incorporate PCC practices. States periodically review and revise their AL regulations, but they need evidence to guide whether and how to make changes, including adopting PCC. Research is an important starting point to inform state policy and practice. This paper suggests topics that still need to be defined and researched, including the effect of PCC practices on quality care and resident satisfaction, work-force development and retention, costs and reimbursement rates, dementia care settings, and the type of AL residence (e.g., small versus large).

### CAREGIVERS USING PERSON-DIRECTED CARE AS A MODEL OF CARE IN ASSISTED LIVING

T. Sharpp, *Betty Irene Moore School of Nursing, University of California, Davis, Sacramento, California*

Assisted Living (AL) was designed to promote autonomy and dignity, ideas of person-directed care (PDC) that put residents' needs and preferences before caregivers' needs to complete tasks. However, little is known about the degree to which caregivers in AL provide PDC. This presentation describes an ethnographic study in one AL community, focusing on ways caregivers used PDC during practice and how residents with dementia responded. Data collection included participant observation, interviews, focus groups, and chart reviews. Analysis was aided by Atlas Ti software. Each caregiver interacted in ways that were sometimes person-directed and sometimes were not. In person-directed interactions, caregivers demonstrated advocacy, affection, attachment, and support for resident autonomy. The trend was for PDC to result in positive resident responses. Because caregivers have tendencies to interact in both person-directed and more staff-centered ways, new models of care must include systems that will support person-directed care as the predominant practice.

### MOVING TO AN INTEGRATIVE MODEL OF RESIDENT CARE: THE EMERGING ROLE OF NURSING

C. McDaniel, *Oregon Health & Science University, Portland, Oregon*

Many older adults living in assisted living (AL) settings have complex social, psychological, physical, and health needs that have not adequately been addressed by early models of AL. Recent research focused on Oregon AL nurses indicates that nursing in AL is an area of expert practice similar to the role of nurses in public health. Four domains of AL practice were identified: 1) Care and clinical manager with expert gerontological nursing knowledge and the ability to teach direct care staff. 2) Systems expert and member of the leadership team able to develop and implement policies and procedures that meet regulatory requirements and best practices. 3) Communicator and facilitator who can work effectively with residents, staff, family members, and other stakeholders. 4) Leader/manager who can respond to multiple and often unexpected demands, prioritize actions, and manage time. Implications for preparing nurses for this emerging role are presented.

### ASSISTED LIVING RESIDENTS AND THEIR PHYSICIANS: CHANGING CARE CONTEXTS

J. Schumacher[1], S. Zimmerman[2], J.K. Eckert[1], P. Sloane[2], *1. Sociology and Anthropology, University of Maryland, Baltimore County, Baltimore, Maryland, 2. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

As more older adults choose to live and age-in-place in residential care/assisted living (RC/AL), their community-based primary care providers are challenged to develop new practice delivery patterns to continue to provide their medical care in this context. The resultant practice patterns range from making no changes, to making on-site room visits to RC/AL patients, to setting up regular clinic hours in an RC/AL-provided exam room. Analysis of data collected as part of an NIA funded study with 180 medical care providers and 80 RC/AL healthcare staff members reveals high percentages (>80%) of providers view their work with RC/AL healthcare staff in terms of a partnership. Data suggest a complex healthcare relationship emerging among some residents, families, physicians, and RC/AL healthcare staff members. Participants report the existence of communication challenges, divergent expectations, and generally high levels of satisfaction (>80%) as characteristic of this emerging relationship.

### MIND THE GAP: FAMILY CAREGIVERS' OF ASSISTED LIVING RESIDENTS PERCEPTIONS OF HOSPICE

M. Volpin, *Oregon Health & Science University, Portland, Oregon*

As the assisted living (AL) population has become older and frailer, the annual death rate in AL has reached approximately 30%. Studies indicate that residents want to die in their AL homes and family members support this desire. Hospice is often brought into AL to meet this goal. This paper presents findings from a qualitative study comprised of interviews of family caregivers and observations of their interactions with hospice-enrolled family members residing in AL. Family members reported positive experiences with hospice in this setting, although their understanding of the role and scope of hospice was often unclear. Hospice was often seen as "gap filler" that prevented the need for residents to transfer to a higher level of care. This presentation focuses on the expectations of family caregivers of hospice within the AL setting, how that changes over time, and the need to create congruence between family expectations and available services.

## SESSION 410 (PAPER)

## END OF LIFE AND PALLIATIVE CARE I

### A COMMUNITY APPROACH TO IMPROVE PALLIATIVE CARE ACCESS

C. Flores[1], C. Russell-McGregor[2], A. Ketchel[3], J. Newman[3,1], R. Newcomer[1], *1. Social and Behavioral Sciences, University of California, San Francisco, San Francisco, California, 2. Sutter Health Sacramento, Sacramento, California, 3. Sutter Health Institute for Research and Education, San Francisco, California*

A study was designed to improve palliative care service provision in the San Francisco Bay Area community through assessment, coordination, education, and outreach. This study addresses the problem of the growing prevalence of advanced chronic illness among aging and other end-of-life populations who are underutilizing palliative care services that can increase comfort and lower cost of care. This presentation includes the results of the assessment of the quality, adequacy and utilization of palliative care services in the San Francisco's Skilled Nursing Facilities (SNF) (n=11) and Residential Care/Assisted Living facilities (RC/AL) (n=17). All licensed SNFs and all licensed RC/ALs with more than 40 licensed beds were contacted and interviewed using a standardized date collection tool. The response rate was 80% for the SNFs and 90% for RC/ALs. Most of RC/ALs had little knowledge of palliative care approaches with the exception of hospice care services. Two (12%) RC/ALs had a specific palliative care program in place. In SNF's the primary source of palliative care coverage is the Medicare hospice benefit, which limits services to those with specific prognosis as opposed to patients' needs for quality end of life care. Both SNFs and RC/ALs faced similar challenges in regards to implementing improvements in utilizations of palliative care services, such as the problems surrounding the use of advance directives and inconsistent participation of physicians in end-of-life planning. This study has informed a team of influential partners in devising an action plan for improving the awareness and use of palliative care services.

### FRAMING EFFECTS OF QUESTIONS ON END-OF-LIFE DECISIONS AMONG LATINO OLDER ADULTS

D. Velez Ortiz, R. Martinez, *Julian Samora Research Institute and School of Social Work, Michigan State University, East Lansing, Michigan*

Background: Making end-of-life decisions is a difficult and painful experience, yet, very little is known about the views of Latino older adults toward directives at the end-of-life. This study examined how the presentation of end-of-life questions influenced Latino older adults in making decisions about their lives. The authors build on prospect theory, which deals with decision-making based on whether a situation is framed positively or negatively (Tversky and Kahneman, 2000). This decisional dynamic can have an influence on the choices relating to end-of-life directives depending on how the situation is framed. Methods: This study used quantitative methods using survey data. It analyzed responses to questions relating to resuscitation and life-support directives from the Decision Making at the End of Life in Mexican American Aged (DELMA) survey (N=110). Surveys were conducted in English and Spanish. Logistic and OLS regression were employed to build the statistical model. Results: Significant framing effects were found in the presentation of end-of-life questions and the decisions Latino older adults made in relationship to their views about resuscitation and life-support in their own lives. Participants were more likely to choose one of the options provided in either resuscitation or life-support according to the order in which choices were presented. Implications: A major implication from these findings is that service providers can affect the choices of Latino older adults facing end-of-life issues. With the rapid growth in the Latino older adult population in the United States, comes an ethical imperative to better understand and respect their perspective about end-of-life issues.

### PALLIATIVE CARE FOR MASS CASUALTY EVENTS WITH SCARCE RESOURCES

A. Wilkinson[1], M. Matzo[2], M. Gatto[3], J. Lynn[4], S. Phillips[5], *1. School of Nursing, Midwifery and Postgraduate Medicine, Edith Cowan University, Joondalup, Western Australia, Australia, 2. University of Oklahoma College of Nursing, Oklahoma, Oklahoma, 3. Bon Secours Health System, Marriotsville, Maryland, 4. Department of Health, Washington, District of Columbia, 5. Agency for Healthcare Research and Quality, Rockville, Maryland*

Catastrophic mass casualty events (MCEs), such as pandemic flu outbreaks or large-scale terrorism-related events, could yield thousands of victims whose needs overwhelm local and regional health care systems, personnel, and resources. MCE conditions will require deploying scarce resources in a manner that is different from the more common single-event disaster. This presentation explores the little discussed "not expected to survive" category, such as those with an existing life-threatening illness; examines the role of palliative care in support of individuals not expected to survive; and recommends specific actions for a coordinated disaster response plan. Semi-structured telephone discussions with key experts and a consensus development meeting identified the issues, responsibilities and resources necessary to integrate palliative care in disaster planning and response including: (1) palliative care's role in a MCE; (2) triage and ensuing treatment decisions for those "likely to die;" (3) critical palliative care services, personnel and treatments settings needed; (4) pragmatic plans for ensuring appropriate training, supplies, and organizational/jurisdictional arrangements; and (5) unusual issues affecting palliative care under MCE scenarios. Palliative care ensures comfort and minimizes the suffering the dying and may also free up resources to optimize the survival of others. Palliative care minimizes the suffering of those who die, ensures comfort, addresses the needs of those who will not survive, and may also free up resources to optimize survival of others. Provision of palliative care services during mass casualty events should be part of current state and local disaster planning and training activities.

## SESSION 415 (PAPER)

## GERONTOLOGICAL EDUCATION

### NORMALIZATION OF THE HARTFORD PARTNERSHIP PROGRAM FOR AGING EDUCATION MODEL

E. Barker, *Social Work Leadership Institute, The NY Academy of Medicine, New York, New York*

The Social Work Leadership Institute (SWLI) of the New York Academy of Medicine is working to increase the number of social workers who specialize in aging through research, policy and education. To achieve this a national initiative; the Hartford Partnership Program for Aging Education (HPPAE), funded by the John A. Hartford Foundation, is working to train leaders in social work and aging through a rotation-based field model and aging-infused curriculum. To date, 72 programs were funded in 33 states. The goal of this initiative is to normalize the educational model in all CSWE accredited MSW programs. Two regions: the south and the northeast, representing an additional 33 schools have begun their normalization process. The normalization strategy engages a grassroots, collaborative network including; Deans and Directors, Field Directors, Students, and Community Partners to expand the HPPAE program and make it a self-sustaining model for education in graduate schools of social work. SWLI utilized the Breakthrough Series Collaborative model developed by the Institute for Health Care Improvement as the theoretical framework to establish the process of normalizing the HPPAE. The National Advisory Panel (NAP), a group of experts in the field of aging, guides the HPPAE; together they comprise the Collaborative Team. Normalization meets the recommendations from the Institute of Medicine's (IOM) 2008 report Retooling for an Aging America. This presentation will focus on how the process of normalization creates a structure for learning, action, and evaluation that engages all schools in making system-level changes in aging education to adopt this model.

### SPECIALIZED GERONTOLOGY CURRICULUM: PREPARING SOCIAL WORKERS FOR ADVANCED PRACTICE

N. Hooyman[1], P.D. Allen[5], Z. Gellis[2], L. Pierce[4], S. Tebb[3], *1. School of Social Work, University of Washington, Seattle, Washington, 2. University of Pennsylvania, Philadelphia, Pennsylvania, 3. Saint Louis University, St Louis, Missouri, 4. University of Missouri, St Louis, St Louis, Missouri, 5. Louisiana State University, Baton Rouge, Louisiana*

The Council on Social Work Education (CSWE) Gero-Ed Center, funded by the John A. Hartford Foundation, prepares faculty and students to meet the geriatric workforce needs of our aging society. The Center's Specialized Gerontology Program provides faculty with the resources to design, implement, and institutionalize gerontological competencies at both the generalist and advanced levels of practice—as a minor, area of emphasis, certificate, specialization, or concentration. Such advanced curriculum is necessary to prepare social workers who can provide leadership during critical care transitions for older adults. Sixteen social work programs nationwide are participating in the two-year Specialized Gerontology Program. The Gero-Ed Center co-Principal Investigator will give a brief overview of the need for specialized gerontological social work curriculum to prepare social workers for advanced practice with older adults and their families, and highlight the role of social work during care transitions. Three social work faculty members who have completed the first year of the Specialized Gerontology Program will discuss the challenges encountered in their planning and implementation phases and describe strategies undertaken to address these. They will highlight the geriatric social work competencies that advanced practice students will attain by completing the specialized curricular structure. Each paper will conclude with lessons learned from their initiatives, which are relevant to other disciplines seeking to offer specialized gero curriculum. Ample time for questions and comments will be provided to engage the audience.

### THE FUTURE OF ACADEMIC GERONTOLOGY PROGRAMS: END OF AN ERA OR TIME OF TRANSITION?

D. Schafer[1], A. Pelham[2], P. Abbott[3], *1. National Association for Professional Gerontologists, Healdsburg, California, 2. San Francisco State University, San Francisco, California, 3. California State University, Fullerton, Fullerton, California*

Background: Gerontological education in the United States is facing a critical challenge. While public awareness of the increasing size of the older population is growing, with the recognition that aging "baby boomers" will require considerably more resources and services, it is not clear that academic Gerontology programs will be able to educate adequate numbers of Gerontologists to meet future workforce demands. A number of recent articles have alluded to the comparative fragility of Gerontology and its possible disappearance as a separate discipline. This paper asks the question: Are we prepared to educate the Gerontologists who will be necessary to meet the needs of the future aging population? Method: To address this question, the number and type of Gerontology/Geriatric programs listed in the seventh (2000) and eighth (2009) editions of AGHE's Directory of Educational Programs in Gerontology and Geriatrics were compared. Results: Results indicate that there was an overall decline in the number of Gerontology/Geriatric programs over the nine-year period nationwide and in virtually every program category (degrees, certificates, minors, etc). Conclusions: Since the previous nine years should have witnessed an increase in Gerontology/Geriatric programs to meet anticipated demand for trained professionals, it is apparent that we are not prepared to educate the next generation of Gerontologists without a transition toward professionalizing the field. A conceptual model describing the interrelationships among accreditation of Gerontology programs and credentialing of Gerontology graduates is presented as a blueprint for strengthening the discipline and insuring that future workforce needs are met.

## SESSION 420 (POSTER)

## GLOBAL AND DIVERSE AGING

### GLOBAL AGING AND HEALTH: NEEDS ASSESSMENT OF COMMUNITY-RESIDING OLDER ADULTS IN BOACO, NICARAGUA

M. Cannon[1], B. Nolan[1], M.B. Neal[1], K. Wilson[2,1], M. Lopez Norori[2], A. DeLaTorre[1], *1. Portland State University, Portland, Oregon, 2. The Jessie F. Richardson Foundation, Clackamas, Oregon*

In 2004, Portland State University's Institute on Aging (IOA) and the charitable non-profit organization the Jessie F. Richardson Foundation (JFR) began jointly designing and teaching an interdisciplinary service learning course on global aging and health with a focus on Nicaragua. Since then, the course has been offered annually, and JFR, the IOA, students, and Nicaraguan governmental and community stakeholders have worked together to create sustainable solutions to support a growing Nicaraguan elder population. Data concerning older Nicaraguans were lacking, and community leaders asked for advice on how to increase the knowledge base about the experience of older adults in their communities. This poster presentation details how, during the summers of 2006 and 2009, faculty and students worked with community partners to assess the needs of community-residing older adults in the province of Boaco, Nicaragua, in the areas of health, financial status, and family support. Both survey research and qualitative interviews were conducted. Local community leaders were trained in interviewing techniques and data collection practices by JFR's staff (a physician) in Nicaragua, and students conducted qualitative interviews with rural elders attending health clinics. The data collected and presented represent some of the first information about the status of older adults in the region and highlight the need for improved access to healthcare, strengthened community support structures, and improved access to basic amenities such as food, potable water, and sanitation services. Additionally, challenges in using survey research and qualitative interviewing in a cross-cultural, collaborative setting are discussed.

### SOCIAL CAPITAL AND HEALTH AMONG OLDER ADULTS IN CHINA: THE URBAN – RURAL DIMENSION

J. Norstrand[1], Q. Xu[2], *1. Boston College, Newton, Massachusetts, 2. Boston College, Newton, Massachusetts*

Introduction: Social capital (SC) is significantly associated with health, however role of urban/rural habitat among older adults in Chinese context remains poorly understood. Goal: Study examined whether SC (examined by bonding, bridging and linking) is associated with physical and emotional health by urban/rural context. Method: China General Social Survey, collected 2005, provided sample of 1250 Chinese elderly (65 years and over). Multiple regression analyses were carried out for physical and emotional health indicators. Three models were tested: socio-demographic indicators entered in Model 1; health indicator entered in Model 2; SC indicators entered in final model. Results: Even when accounting for important socio-demographic and health indicators, Bonding was significant predictor of emotional health ($p<.05$) in urban settings; Bridging and linking were significant predictors of physical health (both $p<.05$) in urban settings. Conclusions: Understanding interaction between type of SC and urban/rural habitat is critical in promoting health among Chinese elders.

## THE IMPACT OF CHANGING SOCIAL ENVIRONMENT ON HEALTH AMONG CHINESE OLDER ADULTS

Y. Li, *School of Social Work, San Diego State University, San Diego, California*

Purpose: Macro social environment in China has dramatically changed and affected many aspects of people's life. However, little empirical evidence is available to demonstrate the existence of those effects. This study investigates how community economic development and social development over time affect the health trajectories of older adults. Method: Employing data from the four waves (1997, 2000, 2004, and 2006) of the China Health and Nutrition Survey (CHNS), this study estimates multi-level growth curve models of functional health, self-rated health, and cognitive function. Results: The results show that: 1) the aspects of community social environment, particularly community household median income, communication development, and time cost for healthcare access exert independent effects on health outcomes over and beyond the elders' individual-level factors; 2) these social environment factors affect the initial health status, but not the consequent development of elders' health; 3) the effects of social environment on health outcomes differ by elder's education and income. Conclusion: Taken together, this study demonstrates that social environment affects health among older Chinese adults independently. Continual progress in economic and social environment could potentially improve health.

## THE HEALTH AND HEALTH CARE OF CANADA'S ETHNOCULTURAL MINORITY OLDER ADULTS: A SCOPING REVIEW

S.D. Koehn[1,2], J. Kozak[1,2], H. Khamisa[1], S. Neysmith[4], K. Kobayashi[3], *1. Centre for Healthy Aging, Providence Health Care, Vancouver, British Columbia, Canada, 2. University of British Columbia, Vancouver, British Columbia, Canada, 3. University of Victoria, Victoria, British Columbia, Canada, 4. University of Toronto, Toronto, Ontario, Canada*

Canada's population is becoming older and increasingly diverse, yet little is known about the health behaviours, attitudes, disease prevalence, and health care access and utilization of ethnocultural minority older adults (EMOA) in Canada. This review aims to (1) consolidate the various types of available knowledge to provide policy-makers, administrators, clinicians etc. with current evidence and possible solutions to address the health and healthcare concerns of this population, and (2) to identify knowledge gaps that will provide direction for future research. Our extensive systematic search of the English-language published and grey literature on this topic focused on Canada and countries with similar health care systems and ethnocultural minority populations. Abstracts of relevant sources were coded in Atlas.ti 5.2.0® to indicate methodological parameters, source, focus of study, participant demographics, location of the study, etc. (almost 400 codes/subcodes). Our search revealed that the qualitative and quantitative literature on this topic is distributed across a broad set of content areas addressed across multiple disciplines with publications in more than 250 diverse journals. Certain ethnocultural groups and health topics are studied more than others, but these similarities may be missed due to inconsistent conceptualization, labeling, and reporting of ethnocultural groups over time and space. Access to information on the health and health care of EMOA requires a search of multiple content areas, and cannot be limited to health databases alone. Situating health and health care for EMOA will require an understanding of how sociocultural categories meaningfully intersect to shape health status and health care access.

## PUERTO RICAN ELDERS' USE OF COMMUNITY-BASED LONG-TERM CARE SERVICES: COMPARISON OF SURVEY AND FOCUS GROUP DATA

N.W. Sheehan, M. Guzzardo, *Human Development & Family Studies, University of Connecticut, Storrs, Connecticut*

While there is consensus that minority elders are underserved by the formal service system, we know relatively little about minority elders' experiences with the long-term care system. The purpose of this study was to explore findings about Spanish-speaking Puerto Rican elders' perceptions of community-based long-term care services by comparing their survey responses to analysis of focus group discussions. A total of 28 Spanish-speaking Puerto Rican elders participated in this study. Elders were recruited from three community settings: conventional housing, public senior housing and specialized Latino senior housing. Participants were in one of three focus groups based on housing type. Quantitative analysis of survey data suggests that while there was some variation across the three groups, the majority of elders receive at least one formal service. One interpretation of this finding is that these elders are connected to the formal service system. However, the focus group data illustrate the problems these elders experience with the system. Overall, the themes emerging from the focus groups indicate that the receipt of services frequently adds stress in their lives. Problematic encounters with the formal service system include psychiatrists, home care workers, and drivers who are not bilingual, poor quality homemaker services, and unresponsive case managers. Also, a striking finding from the focus groups was the limited availability and reliability of family support and assistance forcing elders to rely on formal services. The implications of these findings for future research will be discussed.

## ENGLISH LANGUAGE PROFICIENCY AND DEPRESSIVE SYMPTOMS AMONG KOREAN AMERICAN ELDERS

S. Kang, R. Basham, Y. Kim, *School of Social Work, The University of Texas at Arlington, Arlington, Texas*

Introduction. The effects of English language proficiency and social support on depressive symptoms among 118 Korean American elders in South were examined using the frameworks of the stress coping theory. Despite the rapid growth in the number of Korean American residents aged 65 or older in South in the last decade, policy makers and gerontology practitioners have no empirical data on which to design programs aimed at the specific needs of this elderly population. Methods. A sample of 118 Korean American elders aged 65+ ($M = 75.6$; $SD=7.1$; 69.6% female) completed one and half hour survey. Due to the lack of ethnic enclave resources, such as established community based organizations, the quality of life experience of Korean American elders in South- which was calculated by Geriatric Depression Scale (GDS) - might differ from that of their counterparts living in or near ethnic enclaves. Results. As expected, the proportion of Korean American elders with depressive symptoms was 38% of the sample which is higher than mainstream American elderly population (The standard cutoff point for depression in the total Short form GDS score is > 5). Based on multiple regression analyses, the models (R square = .232) indicate that English language proficiency, perceived health status, and living arrangement were significant correlates in explaining depression scores. The family responsibility expectation factor, the perception of these family value differences between generations and religiosity did not make any significant impact on depression levels.

## CONTRIBUTIONS OF ECONOMIC, HEALTH, AND SOCIAL FACTORS ON LIVING ARRANGEMENT AMONG NON-MARRIED CHINESE AMERICAN ELDERS

D. Nguyen, T. Shibusawa, *New York University, New York, New York*

Living arrangements among elders in the United States are influenced by age, gender, health status, economic resources, availability of family, and culture. While higher numbers of immigrant elders live with extended family than non-immigrant elders, little research has been conducted on immigrant elders who are not married and are at-risk for social isolation. This study examined how economic, social and health factors determine living arrangements among non-married Chinese American elders. Data from the 2006 American Community Survey household and person files were combined for this study. The study sample consisted of 1,020 self-identified Chinese Americans, aged 65 and over, who were not married. Complex sampling weights were applied to sex-specific hierarchical logistic regression analyses to examine the relative contribution of economic, health, and social factors on living arrangement. The results of this study revealed the equal contribution of economic, health, and social factors on Chinese American elders' living arrangement. Specifically, increased age, the foreign born, and having physical or dressing difficulties resulted in increased odds of living alone. Income had differential effects by gender; low personal income increased the likelihood that men lived alone, while this trend was reversed for women. This study identified social and health factors that increase Chinese Americans' vulnerability to living alone. Contrasting previous research, immigrant unmarried Chinese Americans were more likely to live alone. Interventions that reduce the social isolation of Chinese American elders, especially among immigrants, can reduce further risk for health and psychosocial needs of a vulnerable social group.

## THE RELATIONSHIP OF SPIRITUALITY AND RELIGIOUS INVOLVEMENT TO DEATH ANXIETY AMONG KOREAN OLDER PERSONS

H. Yoon[1], M. Huh[2,1], *1. Hallym University, Chuncheon, Gangwon-do, Republic of Korea, 2. Hallym University, Chuncheon, Gangwon-do, Republic of Korea*

This study examines the relationships of spirituality and religious involvement to death anxiety among older persons in Korea. Despite the commonly held view that spirituality and religion buffers against death anxiety, empirical attempts to demonstrate this connection were scarce and have met with mixed results. We hypothesize that higher spirituality and more religious involvements decrease the level of death anxiety. The data for this study came from the Hallym Aging Study conducted by the Hallym University Aging Research Institute in 2003. 1,805 individuals aged 65 and over, who lived in Seoul and Chuncheon were interviewed. Spirituality was assessed by selecting intrinsic measurement part from the Intrinsic/Extrinsic Measurement constructed by Gorsuch & McPherson. Religious involvement was measured by whether or not having religion and number of religious activities. Hierarchical regression analysis showed that spirituality and religious involvement (number of religious activities) had significant effects on death anxiety, while controlling demographic characteristic, number of children, monthly income, health status (self-rated health status and number of chronic diseases), social activities, and social support (R2 change = .19, F = 6.5, p < .001). The total explained variance was 35%. Gender differences in the association between religious involvement and death anxiety were found. Men showed that religious activities decreased the level of death anxiety. The findings support the hypothesis that spirituality and religious involvement are significant factors to reduce the level of death anxiety among older persons, in particular, for men. The practice implications and the relevance of our findings for future research are discussed.

## THE CORRELATION BETWEEN RELIGIOUS SERVICE ATTENDENCE AND PSYCHOSOCIAL INDICATORS AMONG ASIAN IMMIGRANT ELDERS

A. Mui, E.S. Lee*, Columbia University School of Social Work, New York, New York*

This study examines the association between religious service attendance and psychosocial indicators among Chinese and Korean immigrant elderly populations (n = 205) in an Eastern U.S. metropolitan area. Results showed that 85% of the Asian immigrant elderly respondents had participated in different forms of organized religion. Korean elders were more religious than their Chinese counterparts when measured by church attendance. Seventy percent of the Korean elderly respondents attended church at least once a week, compared to 11% of the Chinese elders. Religious service attendance was found to be correlated with better family relationships, higher levels of life satisfaction, and lower levels of depression. Asian older adults were more likely to attend religious activities when they experienced more stressful life events and had better proficiency in English language. Findings suggest that social and spiritual connection with a faith-based community is a powerful spiritual and social support for these Asian immigrant elders. Multiple regression analyses indicated that among the two groups of immigrant elders, church service attendance was also associated with their perception of the importance of religion and their having adult children living nearby. The link between religiosity and the proximity of adult children suggests that they may be more likely to attend church when their adult children support and encourage them. The findings point to the benefits of religiosity in predicting family relationships and the importance of family involvement in the spiritual enhancement of Asian elderly immigrant populations.

## IMPROVING ORGANIZATIONAL CAPACITIES TO RECRUIT SENIOR VOLUNTEERS IN JAPAN

K. Nonaka[1], Y. Fujiwara[1], H. Ohba[1], M. Yasunaga[1], Y. Murayama[1], N. Sakuma[1], H. Uchida[2], S. Shinkai[1], *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, 2. School of Human Science and Environment, University of Hyogo., Hyougo, Japan*

Objective: Because of relatively short history of volunteerism in Japan, volunteer organizations managed by seniors tend to chose semi-formal "group" with weak organizational structures. These groups are often fading because they fail to substitute aged with new younger volunteers. Therefore, our intervention aimed at networking three volunteer groups, to seek a strategy that improves the organizational capacities to attract new volunteers. Intervention: Intervention was conducted from September 2007 to December 2009. We promoted strategic alliance among three volunteer groups, in which senior volunteers engage in reading picture books to children in different areas of Tokyo. Each group consists of about 60 volunteers. Successful alliances are seen to evolve through a sequence of learning-reevaluation-readjustment cycles (Doz, Yves L. 1996. Strategic Management Journal, 17:55-83). Thus, we promoted several joint projects to facilitate a successful alliance processes. Evaluation of intervention: we conducted a focus group interview for the volunteers (n=10), and data were analyzed using the grounded theory approach. We also examined the changes in the numbers of dropout and new memberships. Results: Each partner considered that alliance contributes to the expansion of their groups, and they decided to widen cooperation further. The result indicated factors necessary for successful alliance. For instance, a definition of joint task should be perceived as feasible and beneficial for all partners. Also, successful learning processes is largely influenced by initial conditions and the form of interactions. Conclusion: Initial conditions and formations of alliance are important to develop successful alliance, which contribute the sustenance of organization.

## DIVERSIFICATION OF PUBLIC SERVICES FOR OLDER PEOPLE IN SPAIN AND SWEDEN

G. Sundström[1], D. Puga Gonzalez[2], M. Sancho Castiello[3], M. ToRtosa Chulia[4], *1. Institute of Gerontology, School of Health Sciences, Jönköping, Sweden, 2. Consejo Superior de Investigaciones Scientificas, Madrid, Spain, 3. INGEMA, Madrid, Spain, 4. Universidad de Valencia, Valencia, Spain*

Considerations about (public) services for older people are often limited to institutional care and Home Help. These major services are in many countries supplemented – or substituted – by "minor" services such as transportation, meals-on-wheels, alarm systems and day care. We analyze use of all these services, which are rapidly expanding in Spain - unlike other Mediterranean countries - but declining in Sweden. After initial, dramatic cost increases, Sweden contained costs for services after the 1980s by substituting less intensive, "minor" services for more "heavy" ones, and Home Help is rationed to support only the neediest, before nursing homes provide ever shorter stays at the end of life. Data suggest rather adequate targeting of needs in Sweden, but less so in Spain. Total coverage, all services considered, is about 15 % of the

65+ in Spain and about 25 % in Sweden. In both countries, there is a good deal of overlap between family care and public services, but more so in Sweden. A wide range of services, major and minor, may suit the varying needs of older people and their families more effectively than the choice between nothing, Home Help or institutional care.

### FACTORS OF UTILIZATION AND COORDINATION COMPETENCE OF PROFESSIONAL NETWORKS AMONG CARE MANAGERS IN JAPAN

H. Ishikawa, K. Matsuoka, *Human Welfere Studies, Kwansei Gakuin University, Nishinomiya, Hyogo, Japan*

Purpose: Care mangers under the LTCI in Japan are required to utilize and coordinate their professional networks to provide the appropriate services. However, evaluation studies regarding network utilization and coordination remain quite limited. The purpose of this study is to examine the factors of utilization and coordination competence of professional networks by principal factor analysis. Methods: A total of 998 care managers, who were working at home care support centers in Japan, were randomly selected from the WAMNET list. The survey was conducted by mail from January through February, 2006. There were thirty items regarding utilization and coordination competence of professional networks. Each item was measured by four items ascertained by a four-point scale. Results: As a result of first principal factor analysis with varimax solution, four items were deleted because of low factor loadings. Three factors such as, “basic attitude as professionals”, ”basic knowledge and skills, and ‘approach skills to others’ professional were extracted with 26 items. The reliability (coefficient alpha) was 0.959. As a result of One Way ANOVA, the bigger networks care managers have, the more they utilize and coordinate their networks. Conclusion: The result of this study suggests that care managers are required to enrich basic ethics, knowledge, and skills to coordinate professional networks efficiently. It is necessary for care managers in Japan to undergo basic trainings repeatedly and strengthen their network competence.

## SESSION 425 (SYMPOSIUM)

### HURRICANE KATRINA, ATTACHMENT TO PLACE, AND WIDOWERS ON FILM: A CRITICAL ANALYSIS OF THE IMPORTANCE OF HOME

Chair: *C. Cicero, Gerontology, Univ. of Southern California, Los Angeles, California*

Co-Chair: *C. Detweiler, Pepperdine University, Center for Entertainment, Media and Culture, Malibu, California*

As shown in New Orleans in 2005, policy makers’ attempts to force housing transitions upon residents during civic emergencies often collide with older adults’ resilient attachment to place. Everyday, social service practitioners and family members weigh elders’ rights to self-determination against realistic assessments of their abilities to safely age in place. Theories of place attachment explain why older people choose to stay living in their own homes both in the most acute, life-threatening circumstances such as Hurricane Katrina and also in more chronic situations when elders’ health, emotional, and psychological needs require a step up in the continuum of care. Connections to the home are often based in memories of relationships cultivated there, and in an elder’s transition period following a spouse’s death, the home is a crucial component. This symposium will use the lens of place attachment theory to analyze popular culture’s portrayals of widowers’ transitions in contemporary feature films. After the first presenter outlines the tenets of attachment theory, the second presentation will discuss critical film analysis as a study of society’s attitudes towards aging and older people. Finally, a content analysis on the role of the widower in the films Gran Torino, Up, and That Evening Sun will be presented.

### ATTACHMENT TO PLACE: FROM CIVIC EMERGENCIES TO TRANSITIONAL LIVING

C. Cicero, *Gerontology, Univ. of Southern California, Los Angeles, California*

This presentation will examine place attachment’s theoretical roots and its relevance to older people’s transitions across the continuum of care. Beginning with Powell Lawton, the psychological importance of the built environment will be discussed with justification for revisiting the importance of environmental gerontology in aging research. More specific theories including Rowles’ concept of autobiographical insidedness, Chadhury’s symbolism of the house and place attachment, and Golant’s place therapy and environmental history will be discussed with implications for local policy and practice.

### CONTENT ANALYSIS: AMERICAN FEATURE FILMS’ PORTRAYAL OF AGING AND OLDER PEOPLE

C. Detweiler, *Pepperdine University, Malibu, California*

How has Hollywood portrayed aging populations onscreen? Representations have ranged from crazy old codgers defending their land with a shotgun to over-sexualized grandmothers on the prowl. Such stereotypes may be played for laughs, but eventually harden into ageist attitudes and perceptions. This presentation will utilize critical film theory to analyze the evolving portrayals of elders onscreen. It will address the question: How has Hollywood influenced the American public’s mood and attitudes towards aging and older people?

### AMERICAN PERSPECTIVES ON THE WIDOWER: A VIEW FROM FILM

C. Cicero[1], C. Detweiler[2], *1. Gerontology, Univ. of Southern California, Los Angeles, California, 2. Pepperdine University, Malibu, California*

This presentation will address American perspectives on the widower through analysis of the films Gran Torino (2008), Up (2009), and That Evening Sun (2009). Three veteran actors, Clint Eastwood, Ed Asner, and Hal Holbrook, portray recent widowers facing lifestyle transitions and profound conflicts surrounding their homes. The death of their beloved spouses place them at crossroads. Will they adopt a reclusive posture toward their communities or will they engage their neighbors? Up offers a fantasy version of adventure, with home serving as the means for Carl Fredricksen to reach shared dreams with Ellie. In Gran Torino, a changing neighborhood demographic challenges a hardened Korean war veteran, Walt Kowalski. In That Evening Sun, farmer Abner Meecham is willing to wage war to hold onto his treasured land. The balance between the characters’ self determination and their abilities to age in place presents a significant gerontology dilemma to the public square.

## SESSION 430 (SYMPOSIUM)

### INTERNATIONAL VIEWS ON GOVERNMENT, MARKET AND CIVIL SOCIETY ROLES IN 21ST CENTURY AGING POLICIES

Chair: *M.E. McCall, Psychology, Saint Mary’s College of California, Moraga, California*

Co-Chair: *A.E. Scharlach, University of California, Berkeley, Berkeley, California*

Discussant: *M. Jegermalm, Ersta Sköndal University College, Stockholm, Sweden*

As nations face the common prospect of aging, they also encounter unique circumstances in their specific societies that provide the parameters within which they must strive to meet the needs of older citizens. In this paper we analyze how the intersecting factors of government programs, the economic markets, and civil society factors (fndividuals, families, volunteer organizations, etc.) operate in Japan, Sweden, and the United States. These countries represent different mixes of governmental welfare systems, market forces, and constellations of civil society in relation to social policies for elders. We discuss and analyze how these three factors have changed over time during the last several decades and how these nations are working to adapt to aging populations and design social policies and programs that effectively and efficiently meet the needs of their citizenry and what this portends for the 21st century of policy development and implementation. Will the onus fall on civil society in nations around the world to meet the needs of older persons, or will the role of government remain strong or even grow amidst global economic pressures? What we can learn from different societies about the interaction between the government, market, and civil society and the possibilities to create nations in which all can live and age well? We analyze whether we are likely to observe a development where different countries are adopting similar solutions heading towards a 'welfare mix' versus a 'path dependency' indicating that the cultural contexts have a strong impact on how policies are designed.

### LTC AFTER HEALTH CARE REFORM: CHANGING ROLES OF GOVERNMENT, INFORMAL CARE, AND PRIVATE SECTOR IN US

A.E. Scharlach, *Social Welfare, University of California, Berkeley, California*

This presentation examines the evolving roles of government, informal care, and the private sector in paying for, providing, and overseeing elder care in the United States. Particular attention is given to the impact of recent legislation associated with health care reform. While the US government typically has been considered the payor and provider of last resort, becoming involved only when it would be socially unconscionable not to do so, federal and state governments already are responsible for about 70% of LTC expenditures. Recent policy changes can be understood as efforts to limit government's role, while requiring increased individual responsibility for financing and providing care. Despite concern about increased family responsibility, emerging private sector innovations and peer support models are likely to supplement families as the primary source of elder care in the US, potentially exacerbating disparities in LTC access and quality.

### JAPAN'S SOCIAL POLICIES ON AGING IN THE 21ST CENTURY: FROM FAMILY CARE TO GOVERNMENT CARE

M.E. McCall, *Psychology, Saint Mary's College of California, Moraga, California*

Japan's elderly have traditionally been taken care of by the family, with limited roles of government and market forces. However, in the last part of the 20th century, as the government foresaw the coming changes in age and family structures, the role of the government drastically increased through programs such as the Golden Plan. More recently, with establishment of Public Long-Term Insurances in 2000 and 2005, the roles of the market place and civil society, through neighborhood and other NGO organizations, have increased. Can we expect to see further reallocating of care roles in the 21st century so that a fully-balanced approach is used, or will we see a resurgence of family roles as we move forward?

### SWEDEN'S SOCIAL POLICIES ON AGING IN THE 21ST CENTURY: FROM GOVERNMENT TO MARKET AND CIVIL SOCIETY

M. Jegermalm[2], C. Henning[1], *1. Jönköping University, Jönköping, Sweden, 2. Ersta Sköndal University College, Stockholm, Sweden*

Sweden has been characterised as a "strong state" country with high taxation levels and a policy of universal welfare which aim to cover much of the population. Old-age care has been largely financed and provided by the formal care system, i.e. the public sector. Even though private financing coming from higher fees has become somewhat more common, wholly privately market solutions are still relatively uncommon, especially compared to other countries. It has been assumed that civil society is weak in this kind of welfare system since one would not expect older people and others to be particularly involved as informal caregivers or volunteers in organisations. Research has, however, showed that recently Sweden has scored relatively highly when it comes to civil society vitality (in a comparative context). Will these trends of increasing market and civility society contributions continue through the 21st century, or will the state remain the largest provider?

## SESSION 435 (SYMPOSIUM)

### RUSH ENHANCED DISCHARGE PLANNING PROGRAM: A SOCIAL WORK MODEL OF TRANSITIONAL CARE

Chair: *R. Golden, Older Adult Programs, Rush University Medical Center, Chicago, Illinois*
Discussant: *P.J. Volland, New York Academy of Medicine, New York City, New York*

Researchers estimate that one-fifth of all Medicare beneficiaries are rehospitalized within 30 days of discharge, and that 75% of readmissions are potentially preventable. Poor transition outcomes for older adults yield dangerous results including caregiver burden, medication errors, and mortality. Rush University Medical Center's Enhanced Discharge Planning Program (EDPP) is a social work based transitions of care model that provides phone follow-up and short term care coordination for at risk seniors as they transition from hospital to home. This model places equal importance on psychosocial factors impacting health outcomes, in particular for seniors who are more vulnerable to adverse events post-discharge. EDPP social workers utilize a biopsychosocial framework for assessing post-discharge adherence to the treatment plan including medication compliance, physician visits, strategies for coping with care demands, and other issues that impact health and quality of life. EDPP interventions focus on forming collaborative relationships with existing health care and community based providers. The goals of EDPP are to promote patient safety and satisfaction; to improve the quality of life for older adults and caregivers; and to reduce unnecessary health care costs, particularly those related to preventable rehospitalizations and emergency room visits. This presentation will have four parts: 1. An explanation of the imperative for transitional care programs for older adults, 2. An overview of an innovative social work-driven transitional care program, 3. A presentation of the outcomes from a 720-participant randomized controlled trial of the program, and, 4. A discussion of program sustainability and community partnerships around transitional care.

### EDPP: A SOCIAL WORK MODEL OF TRANSITIONAL CARE

G. Shier[1], S. Altfeld[2], M. Rooney[1], D. Markovitz[1], M. Packard[1], R. Golden[1], A. Perry[1], W. Rosenberg[1], *1. Older Adult Programs, Rush University Medical Center, Chicago, Illinois, 2. University of Illinois at Chicago, Chicago, Illinois*

The Enhanced Discharge Planning Program model provides transitional care to older adults identified as at risk for adverse events after an inpatient hospitalization. Eligible patients are identified daily through a risk stratification tool drawing upon clinical documentation in the hospital's electronic medical record. Master's prepared social workers with experience in health care and aging communicate telephonically with identified older adults and caregivers post-discharge and intervene around a wide array of issues including available social support, transportation, financial resources, health literacy, and mental health. EDPP's social workers utilize their training in care coordination, extensive knowledge of community resources, and understanding of strategies for navigating complex systems to create a bridge between the hospital and the community, ensuring the direction provided by the medical team is not lost. This presentation will describe this innovative model, focusing on program's unique use of social workers as transitional care managers.

### STRATEGY TO SUSTAIN SUCCESSFUL TRANSITIONAL CARE PROGRAMS VIA COMMUNITY PARTNERSHIP

R. Golden, G. Shier, W. Rosenberg, S. McFolling, M. Noonan, *Older Adult Programs, Rush University Medical Center, Chicago, Illinois*

Transitional care programs must remain sustainable to address the challenges posed by looming health care reform, growing attention paid to quality care, and an increasing older adult population. Programs must forge strong relationships with community partners in order to remain viable in today's changing economic and health care climates. Partnerships that streamline care coordination, ensure the accurate transfer of information, and monitor patient and provider follow-up will reduce service duplication, build efficiency across care settings, and transverse silos of care. Findings from Rush University Medical Center's Enhanced Discharge Planning Program provide an evidence-based look at successful methods for building and maintaining effective community partnerships that directly impact quality of life for patients and caregivers. Findings from a randomized control trial will be shared with an emphasis on the program's replicability, impact on policy, and strategy to sustain a successful transitional care program via community partnerships.

### THE TRANSITIONAL CARE IMPERATIVE IN CHALLENGING TIMES

A. Perry[1], S. Altfeld[2], S. Sims[1], T. Johnson[1], M. Rooney[1], R. Golden[1], *1. Rush University Medical Center, Chicago, Illinois, 2. University of Illinois at Chicago, Chicago, Illinois*

Care transitions can be dangerous and costly for older adults moving from one care setting to another. Older adults often suffer from multiple chronic conditions, have physical or cognitive limitations, take multiple medications, experience various psychosocial issues, and are more likely to be socially isolated, depressed, or have financial strain. The lack of support across transitions results in unnecessary readmissions and nursing facility placement, and approximately 40% to 50% of hospital readmissions are linked to social problems and lack of community services. Additionally, changes in Medicare reimbursement policies for patients readmitted within 30 days of a hospital discharge are likely. This presentation will focus on the imperative for transitional care programs that support older adults and their caregivers during the vulnerable transition from hospital to home. Attention will be paid to clinical, institutional, and community factors that influence care transitions for older adults.

### THE ENHANCED DISCHARGE PLANNING PROGRAM: RESEARCH DESIGN AND OUTCOMES

S. Altfeld[1], G. Shier[2], V. Nandi[3], L. Weiss[3], S. Sims[2], T. Johnson[2], A. Perry[2], *1. School of Public Health, University of Illinois at Chicago, Chicago, Illinois, 2. Rush University Medical Center, Chicago, Illinois, 3. New York Academy of Medicine, New York, New York*

A randomized controlled trial moved the Enhanced Discharge Planning Program (EDPP) beyond the pilot stage to test the efficacy of the intervention. The study randomized older adults (N=720) at risk based on clinical and psychosocial criteria. Intervention group participants received a biopsychosocial assessment within 72 hours of discharge and services until problems were resolved. Control group participants received usual care after discharge. A follow-up survey was administered to both groups thirty days post-discharge. Hospital administrative data provided further variables for comparison. The most common reasons for referral were: prior hospitalization in the past 12 months (56.9%), lives alone (36.1%) and high risk for falls (25.3%). Almost 90% of patients had post-discharge needs. Intervention group participants were more likely than control group participants to communicate with their physicians (chisquare=9.88, p=.001) and attend scheduled outpatient appointments (chisquare=26.29, p=.0001). EDPP is a promising intervention with potential to reduce adverse outcomes in this population.

## SESSION 440 (PAPER)

## STATE LEVEL POLICY INITIATIVES I

### THE MINNESOTA RETURN TO COMMUNITY INITIATIVE: PLANNING AND EVALUATION OF A STATE ADMINISTERED NURSING HOME TRANSITION TO COMMUNITY PROGRAM

K. Abrahamson[1], G. Arling[2,3], V. Cooke[4], T. Lewis[4], K. Boston[4], D. Buttke[4], *1. Western Kentucky University, Bowling Green, Kentucky, 2. Indiana University School of Medicine, Indianapolis, Indiana, 3. Regenstrief Institute, Indianapolis, Indiana, 4. Minnesota Department of Human Services, St. Paul, Minnesota*

The Minnesota Return to Community Initiative addresses rebalancing of long-term care by promoting community discharge for nursing home residents who wish to return to the community and can be appropriately cared for in a community setting. This program differs fundamentally from the Federal Money Follows the Person program because it is directed primarily at persons early in their nursing home stays who have not spent down to Medicaid. The initiative, which began April 1, 2010, targets transition candidates based on MDS data. Targeting criteria include admissions with no prior history of nursing home use, preference and/or support for discharge, and fitting a profile of health/functional conditions that increases the probability of successful community discharge. Options counselors from Aging & Disability Resource Centers contact all residents who meet the targeting criteria at admission to assist with the transition. Approximately 700 residents annually will be transitioned back into the community who would have otherwise remained in a facility. Once residents have re-entered a community setting, follow-up occurs at 3 days post discharge, and every 90 days thereafter for up to 5 years. Follow-up assessment focuses on health/functional status, community resources, caregiving requirements, and the influence of these factors on the ability to remain in the community. Findings from the first six months of community transitions and follow-up assessments will be presented. Also, we will discuss how follow-up assessment data are being used to refine targeting criteria, identify risk factors for readmission or adverse health outcomes, and develop needed community support options.

### DO FLORIDA NURSING HOMES IMPROVE QUALITY AS NURSE STAFFING LEVELS INCREASE?

K.S. Thomas, K. Hyer, L. Branch, *School of Aging Studies, University of South Florida, Tampa, Florida*

Publicly reported deficiency citations found in nursing homes during annual inspections are important indicators for residents and families seeking information about nursing home quality of care and quality of life. This study examines the relationship between nurse staffing ratios and deficiencies in Florida nursing homes over a four year period. Data from Florida cost reports (nurse staffing) and the Online Survey Certification and Reporting database (deficiencies) track deficiencies and quality trends for 663 Florida nursing homes between 2002-2005. Using a generalized estimating equation approach, a negative binomial distribution, and a log link function in SAS Proc Genmod, we estimate the relationship between nursing assistant and licensed nursing staff and facilities' deficiency scores. The deficiency score is calculated using CMS' Nursing Home Compare Five-Star Quality Rating System which accounts for the complexity of the scope and severity of the citations. Our results confirmed our hypothesis that higher nursing assistant (est. = -.18; 95%CI = 2.73–3.86) and licensed nurse (est. = -.21; 95%CI = -.32– -.10) staffing levels were predictors of a lower deficiency score after controlling for facility characteristics over time. With a large sample size, longitudinal design, and advanced methods, we have found that there is a relationship among both levels of nurse staffing and quality as defined by deficiency citations.

### TRACKING PROGRESS ON BALANCING THE SYSTEM OF LONG-TERM SERVICES AND SUPPORTS: OHIO GOES PUBLIC

R. Applebaum, S. Mehdizadeh, *Miami University, Oxford, Ohio*

As part of a state effort to create better balance in the long-term care system, a state advisory committee appointed by the Governor recommended the development of a profile tool to track reform progress. The goal was to create an ongoing record of state long-term care performance, documenting such areas as a comparison of community-based and institutional utilization and expenditures, nursing facility occupancy rates, consumer satisfaction, and health care expenditures. The objective of the effort was to have the internet based profile available to policy makers and consumers and to include data across all age groups. This required researchers to use data from a range of sources across various state departments. In many instances the forms of data collections, the unit of measurement, and the long-term care data definitions varied, creating challenges to the development of a comprehensive state profile. This paper will present a version of the profile and will describe the research and policy challenges faced in constructing such a tool.

## SESSION 445 (SYMPOSIUM)

### EXERCISE AS AN AGING INTERVENTION

Chair: *G.J. Lithgow, Buck Institute for Age Research, Novato, California*

Co-Chair: *H.M. Brown-Borg, University of North Dakota, Grand Forks, North Dakota*

The health benefits of exercise are well known and of great importance to the aging population. However, an understanding of what happens at the molecular and cellular level as a consequence of exercise is emerging. In addition, remarkable systemic benefits of exercise provide and great deal of hope that exercise can be thought of as an intervention in aging. Does aging slow or reverse certain features of aging? We will explore this question in this session. Speakers: Adeel Safdar. Ph.D., McMaster University Simon Melov Ph.D., The Buck Institute

## SESSION 450 (PAPER)

### ALTERNATIVE AND FOLK HEALTH PRACTICES

### EXPLAINING AGE-RELATED DIFFERENCES IN USE OF SPECIFIC COMPLEMENTARY AND ALTERNATIVE MEDICINE (CAM) PRACTICES: THE ROLE OF HEALTH BELIEFS

G. Bostean[1], L. Ruppanner[2], *1. University of California, Irvine, Irvine, California, 2. University of Hawaii, Hilo, Hawaii*

Research shows that older adults are less likely to use Complementary and Alternative Medicine than middle-age adults. Yet, there are gaps in understanding the reasons for these age-related differences, and the scope of use of individual modalities. Using the 2007 National Health Interview Survey, this study examines age differences (controlling for sociodemographic and health factors) in use of vitamins, herbs, massage, relaxation and chiropractic care for treatment, prevention, or both. Further, health beliefs are an integral part of the decision to use health care, conventional or CAM, and some attribute middle-aged adults' higher CAM use to their health beliefs, which may be congruent with CAM use due to the influence of the holistic and self-care movements of the 1960-70's. However, to the authors' knowledge, there are no national-level quantitative studies which examine differences in the belief in CAM (or its effectiveness). To address this, this study examines the factors, especially age, related to an individual not using CAM (chiropractor, herbs, and relaxation) because he/she "does not believe in it" or "doesn't think it works." Preliminary regression results reveal significant age differences in the likelihood of using selected CAM practices for treatment versus prevention, and for both compared to prevention only. Generally, older adults are more likely to use some modalities for treatment than for prevention and both, rather than prevention only. Additionally, few age differences in the belief in CAM, or CAM effectiveness, are significant, bringing into question claims about middle-aged adults' predisposition to CAM because of their health beliefs.

### A QUALITATIVE EXPLORATION AND ANALYSIS OF HEALTH PRACTICES AND HOME REMEDIES AMONG ENSLAVED AFRICANS

T.A. Nuriddin, *Sociology and Anthropology, Howard University, Washington, District of Columbia*

Few items are of such importance and consequence as good health. Slavery made it difficult if not impossible for enslaved Africans to lead both healthy and fulfilling lives. Enslaved Africans were constantly under fear of punishment, familial separation, sexual abuse, and intimidation. Forcibly working during such extremely difficult conditions has had an enormous and profound effect on the health and well-being of enslaved Africans in the United States, especially since the institution of slavery lasted for over 200 years. The current paper will examine the recorded interviews of former slaves collected by the Works Progress Administration in the early twentieth century as a context for the present study. A content analysis of the narratives of the formerly enslaved will be utilized in order to capture depictions of health status and subsequent treatment remedies. Although there is not a lack of information about the institution of slavery in the United States, there is less known about the health behaviors of slaves, key differences in health status based on privilege, and how enslaved Africans coped with various health problems. Preliminary analyses indicate enslaved Africans as extremely resilient despite the severity of the institution of slavery based on their participation in an array of health practices including the elaborate use of herbs, roots, and potent elixirs to prevent and treat illnesses.

### "IT'S PROBABLY JUST ARTHRITIS:" TRANSITIONING TO AN INTEGRATIVE MEDICINE (IM) MODEL OF CARE FOR MANAGING PAIN IN LATE LIFE—A CASE STUDY

L. Martin, *Wayne State University, Detroit, Michigan*

What is an older adult to do when they experience a major health transition, but encounter physicians who do not take the problem seriously because of their age? This presentation analyzes the life history and illness narrative of an 89 year old female, and her transition from being a healthy, active older adult to suddenly experiencing debilitating and unmanageable pain. This in depth case study illuminates key themes on life course disruption from dissertation research conducted in an integrative medicine (IM) pain clinic (August 2008-August 2009) that utilizes conventional biomedicine and complementary medicine for treatment. Using Gay Becker's (1997) theoretical approach of continuity and life course disruption, this case study highlights how the clinic's IM approach in treating this older adult patient through a combination of trigger point injections, massage and physical therapy helped her manage her pain and transition from this state of life course disruption back to a state of continuity where she reengaged with her active retirement. Her narratives describe how, due to her age, she experienced negative attitudes from other health care practitioners who did not take her pain seriously, attributing it to "just arthritis." Her previous experiences ultimately led her to this IM pain clinic. Participants attending this presentation will be able to 1) identify the value of qualitative methods in highlighting the nuances that can emerge in life course research, and 2) discuss how in depth case study analysis demonstrates the need for a more integrative model of pain management care in late life.

### ARE "ANTI-AGING MEDICINE" AND "SUCCESSFUL AGING" TWO SIDES OF THE SAME COIN? VIEWS OF "ANTI-AGING" PROVIDERS

M. Flatt[1], R. Settersten[2], R. Ponsaran[1], R. Binstock[1], *1. Bioethics, Case Western Reserve University, Cleveland, Ohio, 2. Oregon State University, Corvallis, Oregon*

The practice of "anti-aging" medicine (AAM) is flourishing. But little is known about whether or how providers of AAM perceive their efforts as aiming to achieve "successful aging" (SA). Through in-depth interviews with practitioners in the U.S., we unearth their perspectives on SA, reveal how these ideas are exemplified in their goals and practices, and compare them to notions of SA in mainstream gerontology. Our sample of 31 providers was drawn from the directory of the American Academy of Anti-Aging Medicine. Interviews ranged from 40-120 minutes. Transcripts were analyzed using codes to capture provider goals and modes of treatment, patient goals and characteristics, and differences between anti-aging and conventional medicine. Analyses reveal that providers hold some views that are surprisingly consistent with those of SA in gerontology and some views that are significant departures. For example, while gerontologists have heavily debated whether and how to conceptualize and measure SA, providers see SA as the very essence of their work. Rather than adopting extreme goals, such as stopping or reversing aging, AAM providers emphasize goals that are remarkably aligned with SA—to lower the risk of disease, maintain functionality, and continue active engagement in life. Providers target ongoing aging processes among those who are in middle age, while gerontologists often focus on successful outcomes among those who are already in late life. Providers are also likely to challenge normative aspects of aging and insist on the need for intense medical interventions to optimize individuals' functioning.

## SESSION 455 (POSTER)

## ANXIETY, DEPRESSION AND DEPRESSIVE SYMPTOMS

### THE ROLE OF PRESENTING SYMPTOMS IN PREDICTION OF TREATMENT RESPONSE TO ESCITALOPRAM AMONG OLDER ADULTS WITH GENERALIZED ANXIETY DISORDER

C.M. Ciliberti[1], E.J. Lenze[2], B. Edelstein[1], *1. Psychology, West Virginia University, Morgantown, West Virginia, 2. Washington University in St. Louis, St. Louis, Missouri*

Generalized Anxiety Disorder (GAD) is common in late-life (Beekman et al., 1998) and is associated with negative outcomes (e.g. Stanley, Diefenbach, & Hopko, 2003; Wetherell et al., 2004). Because of the multiple possible combinations of diagnostic and presenting symptoms that can result in diagnosis, GAD is a heterogeneous disorder. Age-related differences in presentation further complicate the picture (Palmer, Jeste, & Sheikh, 1997). Little is known about which treatments work best for which constellation of symptoms. The present study sought to better characterize the presenting symptoms that differentiate older adults with GAD from those without, and to examine the predictive value of those symptoms on treatment response to escitalopram. Data from 70 participants, age 60 and older, with a primary diagnosis of GAD using DSM-IV criteria, were examined. All were randomly assigned to escitalopram, and completed 12 weeks of blinded treatment. Data from 42 control participants were also examined. Baseline symptoms were derived by examining responses to the Structured Interview Guide for the Hamilton Anxiety Scale (SIGH-A; Shear et al., 2001). The SIGH-A is a 14-item measure which incorporates diagnostic symptoms of GAD and other anxiety symptoms. A discriminant function analysis revealed two symptom clusters (anxious mood and tension) that differentiated GAD and control participants. These symptoms are consistent with the proposed criteria for GAD in DSM-V. A logistic regression analysis found that neither cluster predicted treatment outcome scores when controlling for baseline scores. However, baseline scores on outcome measures were very strong predictors of week 12 scores.

### PREDICTORS OF CHANGE IN QUALITY OF LIFE IN GENERALIZED ANXIETY DISORDER IN OLDER ADULTS

S. Shrestha[1], H.M. Rhoades[3], M.E. Kunik[1,2,5], N. Wilson[1,2], J. Cully[1,2,5], D.M. Novy[4], A. Greisinger[6], M. Stanley[1,2,5], *1. Houston Center for Quality of Care and Utilization Studies, Baylor College of Medicine, Houston, Texas, 2. Houston Center for Quality of Care and Utilization Studies, Houston, Texas, 3. The University of Texas Health Science, Houston, Texas, 4. The University of Texas M D Anderson Cancer Center, Houston, Texas, 5. Michael E. DeBakey Veteran's Affairs Medical Center, Houston, Texas, 6. Kelsey Research Foundation, Houston, Texas*

Quality of life (QoL) is reduced in older adults with Generalized Anxiety Disorder (GAD) relative to those with other anxiety disorders and non-psychiatric samples (Bourland et al., 2000; Stanley et al., 2003). QoL improves following CBT for GAD (Stanley et al., 2003), but little is known about what predicts change in QoL for older people. This study examined predictors of change in QoL using baseline, post-treatment and follow-up data from a randomized clinical trial of CBT, relative to Usual Care (UC), for participants 60 years or older with GAD. Patients were recruited from Kelsey-Seybold Clinic and Baylor Family Medicine, Houston, TX. Linear mixed analysis was used to examine whether treatment groups, demographic variables (age, race, and gender), baseline worry (PSWQ), anxiety (BAI) and depression symptoms (BDI-II), co-morbidity of psychiatric diagnoses, social support (MSPSS), self-efficacy (SES) and optimism (LOT) predicted change in quality of life from baseline to post-treatment and follow-up. Preliminary analyses show that QoL changed significantly from baseline to follow-up, but change was comparable across the two treatment groups. Gender and baseline scores of depression, general self efficacy and social support predicted change in QoL from baseline to follow-up. The interactions between general self-efficacy and social support with time were significant, suggesting a stronger relation between personality variables and QoL at baseline compared to follow-up. Depression and time interaction were not significant. Our findings suggest that the severity of psychological symptoms and personality factors contribute to change in QoL in older adults with GAD.

### EFFECTS OF DAILY UNCONSTRUCTIVE REPETITIVE THINKING ON SLEEP QUALITY IN OLDER ADULTS

J. Mogle[1], J. Smyth[2], M. Sliwinski[1], *1. Gerontology Center, Penn State University, University Park, Pennsylvania, 2. Syracuse University, Syracuse, New York*

Research has established a relationship between unconstructive repetitive thinking (e.g., rumination) and poorer ratings of subjective sleep quality. For example, Cropley et al. (2006) found that elevated levels of rumination in the evening were associated with sleep quality reported the next morning regardless of total sleep time. The current study examined 1) whether end of day unconstructive repetitive thought (URT) predicted sleep quality the following night, and 2) how age moderated this relationship. Given the prevalence of sleep disturbance in the elderly (e.g., Kamel et al., 2006) and that older adults have increased difficulty inhibiting intrusive thoughts (Hasher & Zacks, 1998), we predicted that age would amplify the effect of URT on sleep quality. An experience sampling study was conducted in which participants (Mage = 45.8, range 20-78 years, 53% female) reported on their negative affect (end of day), frequency of URT (end of day), and sleep quality (at waking) on 7 consecutive days. Hierarchical mixed models indicated that higher levels of URT predicted poorer sleep quality during the following night ($p<.05$). This effect was exacerbated by age; sleep quality of older individuals was affected to a greater degree than younger adults by the frequency of URT on the previous day ($p<.05$). These effects remained significant after accounting for evening levels of negative affect and total sleep time. The present findings suggest that age-related vulnerability to the effects of URT may play a role in accounting for the increased prevalence of sleep problems in older adults.

### EFFECTS OF PSYCHOLOGICAL TREATMENTS FOR DEPRESSION ON SLEEP DISTURBANCES IN DEPRESSED PATIENTS

A. Yon[1], F. Scogin[2], *1. G.V. (Sonny) Montgomery VA Medical Center, Jackson, Mississippi, 2. University of Alabama, Tuscaloosa, Alabama*

It has been shown that, for people seeking treatment of insomnia, the severity of depressive symptoms decrease after a course of cognitive behavioral therapy for insomnia; however, questions remain about whether targeting the primary disorder reduces insomnia symptom severity. To answer this question, hierarchical linear modeling was used to analyze archival data collected from 14 separate studies examining the efficacy of several types of psychological treatments for depression in the adult and older adult populations. Only those participants reporting difficulty sleeping prior to treatment were included in the final analysis (n = 948). Results indicated that participating in a course of psychotherapy for depression significantly decreased problems with early-, middle- and late-night sleep when compared to those not receiving such treatment. Also revealed was that the severity of depressive symptoms prior to treatment helped predict sleep outcomes in most; participants experiencing less severe depressive symptoms typically experience fewer sleep disturbances post-treatment than those with more severe symptoms. Clinical considerations generated from the results are offered.

### ASSOCIATION BETWEEN SOCIAL NETWORK AND DEPRESSION AMONG LOW-INCOME ELDERLY KOREAN IMMIGRANTS

B. Kim, L.B. Maradik Harris, *UCLA, Los Angeles, California*

Background: Isolation and lack of social support have been identified as correlates of depression in elderly immigrants. However, few studies have examined the relationship between social network and depression for low-income elderly Korean immigrants in particular. Purposes & Methods: The study aims to investigate the association of social network with depression among low-income elderly Korean immigrants. The study utilized cross-sectional survey design with a sample of 215 older Korean immigrants in Los Angeles County. The Lubben Social Network Scale (LSNS) was used to measure the various aspects of social network. In an attempt to measure depression, the Geriatric Depression Scale (GDS) was utilized. All participants completed face-to-face interviews which included questions about contacts with family members and friends. Results: The study found that 67 of the 215 elderly Korean immigrants reported significant levels of depressive symptoms as measured by GDS. The study indicated that depressed individuals had fewer family members to contact than non-depressed individuals. Moreover, the depressed group was less likely to have close friends to engage in private conversation than the non-depressed group. Implications: Findings suggest that poor social network is significantly associated with depression among low-income elderly Korean immigrants. Family members or service providers should be encouraged to develop strategies to decrease depression by increasing the social networks amongst their elderly clients.

### ASSOCIATIONS OF MUSCULAR STRENGTH AND CARDIORESPIRATORY FITNESS WITH DEPRESSIVE SYMPTOMS IN MEN

R. Liu[1], D. Lee[1], X. Sui[1], J.N. Laditka[2], N. Colabianchi[1], J. Hussey[1], S. Blair[1], *1. Rui Liu, University of South Carolina, Columbia, South Carolina, 2. University of North Carolina at Charlotte, Charlotte, North Carolina*

We sought to examine prospectively the independent and joint association of muscular strength and cardiorespiratory fitness (CRF) with depressive symptoms in men. Participants were 3,704 men ages 20 to 81 years in the Aerobics Center Longitudinal Study. All participants had voluntary strength testing and completed a maximal exercise treadmill test at baseline (1980-1989), in conjunction with a regular clinical examination protocol. An age-specific composite muscular strength score combined the body weight adjusted 1-repetition maximal leg and bench press measures. CRF was quantified by maximal treadmill test duration in minutes. Depressive symptoms were assessed at follow-up with the 10-item Center for Epidemiologic Studies Depression Scale (CES-D). Age- and examination year-adjusted logistic regressions examined the associations between strength, CRF, and the follow-up measure of depressive symptoms. During an average follow-up of 11.5 years, 367 men reported depressive symptoms. In unadjusted results, a significant inverse association was observed between muscular strength and depressive symptoms (p-trend=0.042), and also between CRF and depressive symptoms (p-trend<0.001). The adjusted association between strength and depressive symptoms was not significant. The association between CRF and depressive symptoms remained significant after controlling for potential confounders and further adjusting for muscular strength; the odds of reporting depressive symptoms, comparing middle- and high-CRF thirds to the lowest third, were 0.67 and 0.69 (p = 0.01 each), respectively. Higher baseline CRF was independently associated with lower risk of reporting depressive symptoms at follow-up. Results suggested the possibility that greater muscular strength may have added to the protective effect of CRF.

### HEAVY FOCUS ON INDEPENDENCE EXPLAINS DEPRESSIVE SYMPTOMS AND SUICIDE IDEATION IN RURAL OLDER ADULTS

J.J. Gregg, E.C. Price, R. Petts, J. Cleary, D. Mallow, A. Fiske, *West Virginia University, Morgantown, West Virginia*

Suicide rates in rural areas in the United States exceed those in urban areas. Additionally, older adults are the most vulnerable population for death by suicide and it is estimated that 85% suffer from depression before death by suicide. In prior research, rural ideology (i.e., focus on independence) has been proposed as one explanatory variable in the relation between rural residence and death by suicide (Hirsch, 2006). However, this link has not been established empirically. The current study examined focus on independence as a mediator between rural residence (population ≤ 2500) and depressive symptoms or suicide ideation in older adults. Our sample consisted of 89 older adults who participated in a mailed survey. Emphasis on independence was assessed using the “need for control” subscale of the Personal Style Inventory (PSI; Robins et al., 1994). Individuals who live in rural vs. non-rural areas endorsed higher levels of depressive symptoms, F(1,74)=4.85, p<.05, and greater “need for control,” F(1,80)=6.62, p<.05. In turn, greater “need for control” predicted higher levels of depressive symptoms, F(1,72)=16.19, p<.001. A mediation analysis revealed that “need for control” mediated the relation between rural residence and depressive symptoms. This same pattern was found for suicide ideation. Rural individuals had higher levels of suicide ideation, F(1,84)=4.64, p<.05, and suicide ideation was predicted by higher “need for control,” F(1,79)=4.67, p<.05. “Need for control” mediated the relation between rural residence and suicide ideation. The study suggests that level of emphasis placed on independence may contribute to urban/rural differences in depression and suicidal behavior.

### FUNCTIONAL CAPACITY AND PERSONALITY AS PREDICTORS OF DEPRESSIVE SYMPTOMS AMONG CENTENARIANS

G.D. Da Rosa, P. Martin, J. Margrett, *Human Development and Family Studies, Iowa State University, Ames, Iowa*

The purpose of this study was to investigate the effects of activities of daily living and personality traits as predictors of depressive symptoms among 152 community-dwelling and nursing home centenarians from Iowa. A hierarchical multiple regression analyses were computed using mental status, gender, education, age, and residential status in the first block. ADL was added in the second block, and the Big-5 personality traits were included in the third block. Our results suggest that mental status was a significant predictor of depressive symptoms in all three blocks, suggesting that centenarians with a high number of cognitive errors reported higher levels of depressive symptoms, ($B$=.30; $p$ < .05). There were two statistical trends the first suggests that women were more likely to report high levels of depressive symptoms, ($B$= -1.86; $p$ > .05), and the second trend was found for ADL on predicting depressive symptoms, ($B$=.13; $p$ > .05), indicating that centenarians with higher ADL impairments were more likely to report depressive symptoms. The personality variables in block 3 significantly contributed to the increase in variance explained in depressive symptoms among centenarians, ($F_\Delta$= 14.99; $p$ < .001; Adj.$R^2$=.61).Centenarians with high levels of Neuroticism and lower levels of Extraversion showed more depressive symptoms, ($B$=.46; $p$ < .001; $B$ =-.17; $p$ < .05), respectively. Our study concluded that mental status, ADL, Neuroticism, and Extraversion was significantly associated to lower depressive symptoms among Iowans' centenarians. The influence of ADL on depressive symptoms was in part explained by the personality variables.

## META-ANALYSIS OF THE EFFECTS OF EXERCISE AND USE OF NINTENDO WII FOR REDUCING DEPRESSION AMONG OLDER ADULTS

G.Y. Slater[1], D. Dickin[2], M. Dishman[1], *1. Social Work, Ball State University, Muncie, Indiana, 2. Ball State University- Exercise Science, Muncie, Indiana*

Background: It is well established that increasing activity helps improve a variety of health and mental health outcomes in late life, including depression. The purpose of the present meta-analytic study was to 1) analyze the effects of exercise on depression outcomes, 2) compare traditional exercise to Nintendo Wii on cardiovascular outcomes. Methods: We searched the following databases: Academic Search Premier, JStor, ERIC, Medline, CINAHL, HealthSource (Nursing Academic Edition), Military and Government Collections, PSYCHarticles, and PsychInfo. Key words used in the search were older adults, elders, elderly, geriatric, treatment, intervention, activities, mental health, depression, anxiety, self-efficacy, physical activity, exercise, Wii, Nintendo, and video games. Reference lists and several key journals were hand-searched for additional articles. Sixteen studies (N=8,406) were used in the final analysis. Results: Effect sizes ranged from no effects to significant effects (r= .770) with a moderate mean effect (r= .288) for the 13 exercise studies (N=8,361). Effects for Nintendo Wii studies (N=45) ranged from no effect to significant effects (r=.984) and mean effects were strong (r=.641). Nintendo Wii was significantly more effective than traditional exercise (F1, 14= 3.204, p=. 095). Conclusions: Small samples and few published studies of Nintendo Wii's effects were a limitation. Nintendo Wii shows significant promise for improving health and mental health outcomes, however future RCT or matched controls designs are needed.

## GENDER DIFFERENCE IN THE RELATIONSHIP BETWEEN SPOUSAL SUPPORT AND DEPRESSIVE SYMPTOMS AMONG OLDER ADULTS

N.G. Choi, *University of Texas at Austin, Austin, Texas*

Based on data from the first wave of the National Social Life, Health, and Aging Project (2005-2006), the purpose of this study was to examine gender difference in the relationship between depressive symptoms and spousal support among persons age 57 and older (n=2,924), controlling for other risk and protective factors, including support from other sources. Nearly 70% of the sample reported that they were married or cohabiting with a partner and provided data on their perception of spousal support using a 4-item spouse support scale. The scale scores, ranging from 4-12, were categorized into three groups to represent low, medium, and high levels of support. The nonmarried respondents served as the reference group. Depressive symptoms were measured with the 11-item Center for Epidemiologic Depression Scale (CES-D). Women reported a significantly higher level of depressive symptoms. Married/partnered women also reported a slightly higher level of spousal support than their male counterparts (p <.05). The gender-separate, hierarchical multivariate regression results show that the high level of spousal support was significantly negatively associated with the CES-D scores for both genders. On the other hand, the low level of spousal support was significantly positively associated with the women's CES-D scores only. Spousal support alone explained 1.8% and 3.8% of the variances of the CES-D scores for women and men, respectively. The addition of the spousal support variable did not change the relationship between the CES-D scores and the other risk and protective factors for both genders. The implications for the gender difference are discussed.

## COMPARING THREE TIME-METRICS TO EXAMINE CHANGES IN LATE-LIFE DEPRESSIVE SYMPTOMS OVER AGING, DISABLEMENT, AND MORTALITY PROCESSES

E.B. Fauth[1], D. Gerstorf[2], N. Ram[2], B. Malmberg[3], S.H. Zarit[2,3], *1. Family, Consumer, and Human Development, Utah State University, Logan, Utah, 2. Pennsylvania State University, State College, Pennsylvania, 3. Jönköping University, Jönköping, Sweden*

Developmental processes are inherently time-related. However, time can be characterized in different ways and indexed in relation to different starting or ending points. The appropriate time metric to best describe a developmental phenomenon of change depends on the underlying process. To test whether depressive symptoms are primarily driven by aging (primary), disablement (secondary), or mortality (tertiary) processes, we compare descriptions of late-life depressive symptoms across "time from birth", "time to and from the onset of disability", and "time to death" time metrics. Data come from four Swedish studies of individuals aged 70-100+ (N=1,067) who measured every two years for up to five occasions of measurement. Depressive symptoms were assessed using a 10-item version of the CES-D. Disability onset was indexed as the wave at which impairment in Activities of Daily Living were first reported. Mortality data were derived from follow-up records. Applying growth models, we use model fit indices and the amount of variance accounted for to compare descriptions of change in depressive symptoms across the three time metrics. Results indicate that "time to and from disability onset" and "time to death" models provided more efficient descriptions of changes in depressive symptoms than did "time from birth" models. Our findings suggest that these late-life changes are less likely driven by aging processes (primary aging), but rather by processes underlying disablement (secondary aging) and mortality (tertiary aging). By better understanding the mechanisms underlying trajectories of late-life depressive symptoms, we may be better equipped to promote and maintain well-being for older individuals.

## COMORBID ANXIETY IN OLDER PRIMARY CARE PATIENTS WITH MAJOR DEPRESSION: EFFECTS OF VASCULAR RISK

A.R. Azar[1], M.P. Chopra[1,2,3], J. Rudolph[1,4,3], *1. VA Boston Healthcare System, Brockton, Massachusetts, 2. Boston University School of Medicine, Boston, Massachusetts, 3. Harvard Medical School, Boston, Massachusetts, 4. Brigham and Women's Hospital, Boston, Massachusetts*

**Introduction:** While previous research has identified risk factors for comorbid anxiety and depression in later life, the impact of vascular risk on this relationship is less understood. This analysis examined whether increasing vascular risk was associated with comorbid anxiety disorder diagnosis in patients with major depressive disorder (MDD) using the PRISM-E study. **Methods:** Older primary care patients with MDD were included in the analyses (n=792). Depression and anxiety disorder (i.e., panic disorder, GAD) were diagnosed according to DSM-

IV criteria using a structured interview. Self-report vascular risk factors (i.e., hypertension, diabetes, heart trouble, hardening of the arteries, smoking) were summed and dichotomized as follows: Low Risk=0-1, High Risk=2+. Outcome was defined as the absence or presence of an anxiety disorder. Multivariate logistic regression examined the effect of vascular risk on anxiety diagnosis in MDD while accounting for related demographic and clinical factors. **Results:** Thirty-three percent (n=265) of study participants with MDD also had a comorbid anxiety disorder. In bivariable analyses, the presence of ≥2 vascular risk factors was associated with higher rates of comorbid anxiety (Low=26% vs. High=39%, p<0.001). After controlling for demographic and clinical factors, (high) vascular risk was independently associated with anxiety diagnosis in MDD (OR=1.62, 95% CI=1.17-2.26). **Conclusions:** This analysis found that elevated levels of vascular risk were independently associated with anxiety diagnosis in older patients with major depression. Because treatment options and goals may be altered in patients with both MDD and anxiety, the impact of vascular risk in patients with these comorbid conditions warrants further study.

## PREDICTORS OF DEPRESSION AND QUALITY OF LIFE BETWEEN THE RURAL AND URBAN ELDERLY IN SOUTH KOREA

Y. Son*, Ederly Care Management, Catholic University of Pusan, Busan, Republic of Korea*

This study attempted to investigate the factors of influencing depression and examine six areas of quality of lives. A sample of 2,955(Urban 1,752; Rural 1,203) Korean elderly was drawn from the first wave of Korean Longitudinal Study(KLoSA). Six areas of quality of lives included social networks with adult children, supportive social networks, health-related behaviors, utilization of health services, health-promoting behaviors and several domains of life satisfactions. The socioeconomic disparity between the urban and rural residence pervaded into most areas of quality of lives. Being the rural elderly was more likely to be poor, weaker in family networks, fewer in social networks, and 49.1% of the rural elderly was reported to have depression. The urban elders tended to have adult children living nearby, see more frequently, and make more contacts than rural counterparts. The rural residents were more likely to receive both monetary and non-monetary assistance, tended to have higher level of regular exercise, and use public health facilities four more times than the rural counterparts. Although the rural residents had fewer chronic diseases, they rated their conditions worse than urban older people and viewed their future life condition as negative. The results of multivariate analyses with rural adults showed that having contact with adult children weekly and social networks tended to lower level of depression, suggesting the effectiveness of informal networks. Public health plans alleviating and preventing depression were suggested.

## THE EFFECTS OF PHYSICAL HEALTH AND FINANCIAL SATISFACTION ON DEPRESSIVE SYMPTOMS AMONG OLDER KOREAN IMMIGRANTS IN CANADA: DOES ACCULTURATION MATTER?

W. Kim, Y. Chen*, University at Buffalo, Buffalo, New York*

Korean immigrants experience higher levels of depressive symptoms than do other ethnic/racial groups. As one of the most recent groups to immigrate to Canada, Korean immigrants may experience higher levels of adjustment stress. The purpose of this study was to investigate factors that influence depression among older Korean immigrants in Toronto. A total of 149 participants ages 60 years or older (mean age=74.07, SD=8.24) completed face-to-face interviews conducted in Korean. Hierarchical regression analyses were performed in four steps: 1) demographic variables, 2) acculturation variables (years of immigration and English proficiency), 3) social integration (living arrangement and social activity), and 4) physical health and financial satisfaction. At step 1, education was negatively associated with depression (b=-.291, p<.05). At step 2, after adding acculturation variables, acculturation did not appear to be significant. At step 3, after adding social integration variables, the model was significantly improved and social integration variables were significantly associated with depression scores (living arrangement: b=.224, p<.05; frequency of social activity: b=-.233, p<.05). In the final model, physical health status (b=-.379, p<.001) and financial satisfaction (b= -.169, p<.05) were negatively associated with depression. The final model explained about 38% of variance of depression in the sample. The results suggest that health and financial status, and not acculturation, are important factors to explain the levels of depression in older Korean immigrants. Implications for future study and social work practice will be discussed.

## MULTI-METHOD ANALYSIS OF DEPRESSION IN GRANDMOTHER CAREGIVERS

C. Musil, A. Jeanblanc, J.A. Zauszniewski, C. Warner*, Case Western Reserve Univ, Cleveland, Ohio*

Depressive symptoms are among the most commonly measured outcomes in gerontology research. Since different methods of assessing depressive symptoms may produce varying conclusions, the purpose of this secondary analysis was to examine concordance of the Center for Epidemiological Studies-Depression (CES-D) Scale with other methods of identifying mental health problems, collected at the same time wave. This sample included 323 community-dwelling women who participated in two waves of a study on caregiving to grandchildren. Using mailed questionnaires, participants completed the CES-D, a checklist of provider-diagnosed mental health problems (depression, anxiety, bipolar disorder) and a self-report of mental health problems and health actions. Analysis: CES-D scores were classified as low (<16), moderate (16-22) or high risk (>23) for clinical depression. Chi-square tests and analysis of variance were used to compare risk groups on provider-assessed and self-reported mental health problems. Results: There was a strong concordance between methods. For example, 21% had CES-D scores >23, and of those, 69% had been diagnosed with clinical depression by a health provider, and 78% indentified depression as a current problem. Across groups, 36% identified depression as a health problem, 65% considered it to be an illness, and 87% reported that they treat their depression: 71% take medication, 20% see a physician/mental health specialist, 14% pray or meditate, and less than 1% use alternative treatments. Longitudinally, 78% reporting a diagnosis of depression did so in the following wave. Using multiple methods to gather depressive symptom data appears to enhance the validity of study findings.

## PREDICTING THE TRAJECTORIES OF DEPRESSIVE SYMPTOMS AMONG SOUTHERN, COMMUNITY-DWELLING OLDER ADULTS: THE ROLES OF RELIGIOUSNESS

F. Sun[1], N. Park[2], L. Roff[3], D. Klemmack[3], M. Parker[3], H. Koenig[4], P. Sawyer[5], R.M. Allman[5], *1. School of Social Work, ASU, Phoenix, Arizona, 2. University of South Florida, Tampa, Florida, 3. The University of Alabama, Tuscaloosa, Alabama, 4. Duke University, Durham, North Carolina, 5. The University of Alabama at Birmingham, Birmingham, Alabama*

Purposes: This study examined the effects of religiousness on the trajectories of depressive symptoms in community-dwelling older adults over a four-year period. Methods: Five waves of data from the University of Alabama at Birmingham Study of Aging were analyzed using a hierarchical linear modeling (HLM) method. The study included 624 participants (Mage = 74, SD=5.5, at baseline) who completed interviews annually from 1999 to 2003. Participants were 49% African American and 51% Caucasian; 53% were women; and 49% resided in rural areas. Depressive symptoms were measured using the short form of the Geriatric Depression Scale (M = 1.98, SD = 2.1). Religiousness was assessed by 3 subscales (i.e., religious service attendance, private religious activities, and intrinsic religiousness) of the Duke University Religion Index. Covariates were self-rated health, social support, ADL/IADL limitations and cognitive impairment. Results: The HLM results indicated that older adults experienced a gradual decline in depressive symptoms during the first two years, followed by a steady increase during the last two years. Participants who attended religious services more frequently had fewer symptoms of depression at baseline ($p < .01$). However, neither religious service attendance nor private religious activities were related to the trajectory of depressive symptoms. Participants with the highest levels of intrinsic religiousness experienced a steady decline in depressive symptoms, while those with lower levels of intrinsic religiousness experienced a short-term decline followed by an increase in depressive symptoms ($p < .05$). Implications: Intrinsic religiousness may have salutary effects on depressive symptoms in older adults with aging.

### HEALTH AND DEMOGRAPHIC PREDICTORS OF LONGITUDINAL CHANGE IN DEPRESSION SCORES

R.F. Kennison, *Psychology, California State University, Los Angeles, Los Angeles, California*

Age related longitudinal trends in the Health and Retirement Study's CES-D-8 depression score data (n = 24,733) were modeled from ages 51 to 90 with up to seven test occasions. Predictors of change included disease indicators (arthritis, high blood pressure, heart disease, diabetes, lung disease, cancer, and stroke) and demographic measures (sex, and education). Of the unconditional models examined, the best fitting included linear and quadratic slopes; both slopes indicating small but reliable increases in depression over age. However, when the health and demographic predictors were added in an associated conditional model, the observed linear and quadratic increases in depression disappeared, suggesting that age related increases in depression are due to the presence of various diseases, and being male and less educated. With the exception of cancer, the presence of any diseases resulted in higher depression scores at the intercept. Being male and having less education also predicted higher depression scores. The linear slope only was predicted by sex, and education, whereby linear increases in depression were associated with being male and lower education. The quadratic slope was not reliably predicted by any predictors. The importance of accounting for disease and demographic information when assessing depression is discussed.

## SESSION 460 (SYMPOSIUM)

### CONDUCTING MIXED METHODS AGING RESEARCH: VARIOUS WAYS OF INTEGRATING QUALITATIVE AND QUANTITATIVE METHODS

Chair: *L.K. Donorfio, Human Development and Family Studies, University of Connecticut, Waterbury, Connecticut*
Discussant: *P.H. Van Ness, Yale University, New Haven, Connecticut*

Last year the Qualitative Research Interest Group co-sponsored a symposium with the Measurement, Statistics, and Research Design Interest Group on various ways of integrating qualitative and quantitative methods in conducting mixed methods aging research. It was highly successful, with the audience requesting a similar symposium for this year. This symposium will present a balanced panel of researchers from both interest groups who have conducted aging research using mixed methods designs. The presenters will discuss the strengths and challenges of using both methods together, the thought processes behind conceptualizing a mixed methods design, and how the results can be effectively integrated and communicated. The symposium discussant will consider the strengths and challenges to conducting and communicating mixed methods research and how using mixed methods designs can deepen our understanding of aging issues.

### RURAL APPALACHIAN ADULTS WITH MULTIPLE MORBIDITIES: THE ROLE OF SOCIAL SUPPORT

S.H. Bardach[2,1], Y.N. Tarasenko[2,3,4], N. Schoenberg[2], *1. Graduate Center for Gerontology, University of Kentucky, Lexington, Kentucky, 2. University of Kentucky - Department of Behavioral Science, Lexington, Kentucky, 3. University of Kentucky - Department of Epidemiology, Lexington, Kentucky, 4. University of Kentucky - Department of Health Services Management, Lexington, Kentucky*

Rural Appalachian adults with scarce personal and community resources and multiple chronic conditions face considerable challenges in managing their illnesses. We conducted a series of in-depth interviews with 40 adults, employing both qualitative and quantitative measures, to examine how these individuals with multiple chronic conditions describe the potentially valuable asset of social support. Participants generally felt support was available, though perceptions of emotional/informational support were lower than other aspects of support. Participants' experiences suggest that placing a high value on independence, coupled by an emphasis on clinical and medical needs, leads to less reliance on social support than the literature suggests. Thus, social support may be a valuable asset, but may not play as prominent a role in managing health care needs as previously believed.

### USING MIXED METHODS IN A STUDY ON ATTITUDES

A. Kydd, *Health Nursing and Midwifery, university of the west of scotland, Hamilton, Lanarkshire, United Kingdom*

Measuring attitudes and exploring where such values and beliefs originate is of great interest to researchers. However, it is well-acknowledged in the literature that attitudes can be difficult to research. This paper discusses a large international study using a mixed methods approach. The study seeks to explore the attitudes of health care workers towards those who work with older people. The UK study has 474 returned questionnaires to date and 102 people willing to be interviewed. This paper focuses on the rational for a mixed method approach.

### A MIXED METHODS APPROACH TO UNDERSTANDING SERVICE NEEDS OF NEW YORK STATE CAREGIVERS

B. Chandler, *LIGEC, Stony Brook University, Stony Brook, New York*

In an effort to study the future service needs of elderly New Yorkers and their caregivers so that data-driven policy recommendations could be made to legislative decision-makers, the Center for Aging Policy Research at the Stony Brook University School of Social Welfare created "the Family Caregiving Research Program." In designing this program, a decision was made to use both qualitative and quantitative research methods. First, a statewide telephone sample survey was undertaken to establish baseline and statewide statistical prevalence data on the magnitude, intensity, type and repercussions of informal, unpaid family caregiving. Following that, a focus group study was conducted to gain an in-depth understanding of patterns of informal family caregiving and service use, especially among various ethnocultural groups. This paper will discuss both the rewards and challenges of using a mixed methods approach.

### DEVELOPING A SHORT GERIATRIC DEPRESSION SCREENING TOOL USING MIXED METHODS

F. Yang[1,2,3], D. Tommet[1], E.T. Crehan[1], B. Forester[4,3], S. Pinals[5,3], A.P. Abrams[2,3], R. Jones[1,2,3], *1. Institute for Aging Research, Hebrew SeniorLife, Boston, Massachusetts, 2. Department of Medicine, Division of Gerontology, Beth Israel Deaconess Medical Center, Boston, Massachusetts, 3. Harvard Medical School, Boston, Massachusetts, 4. McLean Hospital, Boston, Massachusetts, 5. Cambridge Health Alliance, Cambridge, Massachusetts*

Using a dominant-less dominant design for mixed methods research, we conduct a simulation study and small pilot validation study on a quasi-adaptive (paper-based) short (QASh) form for late-life depression with a short qualitative semi-structured interview regarding what depression means to a diverse community dwelling older adults (N=69). The QASh form for late-life depression was developed based on item response theory from the National Institutes of Health (NIH) Patient Reported Outcomes Measurement Information System (PROMIS) emotional distress item bank. We refine the QASh form for late-life depression based on a short qualitative interview that entailed a free-listing portion adapted from Barg and colleagues' (2006) research: "Please provide a list of words that describe: a) a person who is depressed; b) yourself when you are depressed, down in the dumps, or blue." We suggest a refined QASh form for late-life depression that considers acculturation characteristics and race/ethnic differences for further pilot testing and validation.

## SESSION 465 (POSTER)

## ELDER ABUSE AND PROTECTION

### WHO CARES FOR THEM?: MOTIVATIONS OF VOLUNTEER TEMPORARY GUARDIANS TO ELDERLY PERSONS

A.B. Edwards, C.M. Gillotti, E.R. Swaney, D. Robbins, *Institute for Social and Policy Research, Purdue University Calumet, Hammond, Indiana*

The purpose of this study was to investigate volunteer guardians for elderly persons and to descriptively examine their motivations for volunteering in this type of program. Changes in the demographic structure of the United Sates point to the growing need for care from non-family members. For example, in 2005, 9.9% of women in the U.S. over the age of 65 were childless and that percentage is only expected to increase (Kinsella & He, 2009). Data was obtained from the Volunteer Advocates for Seniors (VAS) program. The VAS program is a public form of temporary guardianship for cognitively incapacitated adults 55 years and older in Northwest Indiana. The VAS program is run by a project manager and two full-time program coordinators in conjunction with the hospital president, and most importantly, the Lake Superior Court system. The applications of 60 volunteers for the VAS program were content analyzed independently by four researchers. Different themes were developed by the researchers based upon common answers. Results indicate that motivations for becoming a volunteer guardian fall under themes which include: Personal experience with caregiving; Experiences in Job/Profession; Desire to give back to the community; Personal gain (knowledge, skills); and Religious/Spiritual. Implications for similar programs, as well as the future need for volunteer guardians will be discussed

### RISK FACTORS FOR FINANCIAL EXPLOITATION AND FRAUD AMONG AN URBAN ADULT POPULATION IN THE UNITED STATES

S. Strasser[1], B. Payne[2], A. Mistretta[1], P.S. King[3], *1. Georgia State University Institute of Public Health, Atlanta, Georgia, 2. GSU Department of Criminal Justice, Atlanta, Georgia, 3. Georgia Department of Human Services, Division of Aging Services, Atlanta, Georgia*

INTRODUCTION: Elder mistreatment is a growing problem in the United States. Current conservative estimates are that between 1-2 million older adults are victims of abuse every year. A common form of elder mistreatment is financial exploitation. AIM: The purpose of this study is to explore possible risk factors of financial exploitation among adults living in an urban area of the U.S. Data from older and younger respondents was examined to see if risk factors were different between the groups. METHODS: A random digit-dialing telephone survey was administered to an adult sample in the Norfolk Virginia metropolitan area. Descriptive statistics, t-tests, cross-tabulations, chi-square, and regression analyses were calculated to determine if participant age, ethnicity, gender, education and income were associated with reported telephone exploitation and fraud. RESULTS: Seven hundred and forty surveys were completed. Financial exploitation was reported by nearly forty percent of the sample (39.2%). A smaller sample reported being victims of fraudulent telephone scams (7.9%). An association was found between increasing age and increasing victimization by telemarketing fraud. Participant income was not significantly correlated with victimization. However, ethnicity, education, and gender were found to be significantly associated with telephone exploitation. DISCUSSION: The results from this study demonstrate that telephone exploitation presents a threat to urban-dwelling adults. Older adults are slightly more vulnerable to financial exploitation than younger adults. These results can help inform tailoring of future programming so that the health promotion / protection messages and interventions for vulnerable populations can be optimized.

### CONCEPTUALIZATIONS OF MISTREATMENT AMONG AMERICAN INDIAN ELDERS

L.L. Jervis, W. Sconzert-Hall, *University of Oklahoma, Norman, Oklahoma*

The problem of how to conceptualize elder mistreatment goes back several decades. Issues of conceptualization are especially important for ethnic minority populations, who may have perspectives that differ from the dominant society. This mixed methods CBPR study, which examined perceptions of mistreatment among 100 urban and rural older American Indians, permits a rare glimpse into how Native elders themselves understand this issue. Here, good treatment emerged as a complex mixture of behavioral factors (being taken care of, having one's needs met, spending time with family members, and being included in things) and attitudinal factors (being respected and being loved). Poor treatment, conversely, was defined as financial exploitation, neglect, psychological abuse, physical abuse, as well as lack of respect. Many of the elders who stated, in response to open-ended questions, that they had been mistreated did not endorse abuse items on the structured survey. Some of these elders sincerely felt that they were not treated well by family and were quite unhappy about it, but their perceived mistreatment did not come close to the level of a reportable offense. The complaints of these elders often revolved around feeling taken advantage of in a variety of ways (e.g., being unappreciated, financially exploited, babysitting excessively, not getting the help they needed). These findings point to the importance of understanding the underlying constructs that elders have in mind when they describe optimal and suboptimal treatment, and suggest that behavior that is highly distressing to elders may be outside the purview of elder protective services

### THE ROLE OF ELDER PARENT/ADULT CHILD RELATIONSHIP QUALITY IN OLDER ADULT PHYSICAL ABUSE: AN ECOLOGICAL, BI-FOCAL, PERSPECTIVE

L.B. Schiamberg, L. von Heydrich, *Family and Child Ecology, Michigan State University, East Lansing, Michigan*

Overview: The purpose of this investigation was to identify the risk factors involved in elder physical abuse by adult children in the family/community setting. An ecological theoretical perspective was used to model the contextual risk factors of elder physical abuse, moving from the immediate bi-focal, adult child/older adult relationship, to the effects of more distal contexts involving broader social relations/connections and support resources. Design and Methods: A Random Digit Dial (RDD) sample of 203 non-institutionalized, English-speaking, older adults (65 years+) from the Midlife Development in the United States (MIDUS II, 2004-2006) study was used. LISREL/ SEM data modeling was utilized to examine causal pathways and associations of elder physical abuse, involving 1) the immediate, bi-focal, older adult/adult child context (e.g. older adult demographics, physical/emotional health, and behavioral factors, adult child characteristics and relationship quality) and 2) broader social support contexts. Mplus, PAXW, and SYSTAT statistical software packages were used for data modeling. Results: Older

Adult Health (γ = -0.738; t-value = -3.072; p = 0.002), Adult Child Characteristics (γ = -0.270; t-value = -3.422; p = 0.001), and Older Adult Social Isolation (γ = -0.329; t-value = -2.157; p = 0.041), as latent factors, were significantly related to physical abuse when mediated/ moderated by the Victim/Adult Child Relationship Quality (γ = -0.831; t-value = -3.908; p = 0.000). Implications: This study supports the usefulness of an ecological, bi-focal, perspective for both understanding the complexity of elder physical abuse, including the critical role of the relationship quality, and developing sensitive interventions.

### IN THEIR SHOES: STRATEGIES DEVELOPED BY CERTIFIED NURSES' ASSISTANTS TO MANAGE AND PREVENT RESIDENT-TO-RESIDENT VIOLENCE IN NURSING HOMES

S. Sifford, *Arkansas State University, State University (jonesboro), Arkansas*

Resident-to-resident violence (RRV) is a threat to the safety and quality of life of residents in nursing homes. To date, little evidence exists regarding RRV or strategies for managing and preventing it. As part of a larger qualitative study that explored RRV and the triggers that precede it, strategies developed by certified nurses' assistants (CNAs) for the prevention of RRV were also explored. Using a semi-structured interview guide, eleven CNAs were asked what strategies they used to prevent and manage RRV in the nursing home. Data were analyzed using content analysis and constant comparison. Four factors that affected the ability of CNAs to manage and prevent RRV were "knowing the residents," "keeping residents safe," "spending quality time," and "something to do." These factors were combined into the over-riding theme "distraction." The results of this study reveal useful information regarding the successful prevention and management of RRV and may provide important baseline information for the future development of interventions.

## SESSION 470 (SYMPOSIUM)

### EXPANDING PARADIGMS OF CARE AND SUPPORT: CHALLENGES FACED AND LESSONS LEARNED

Chair: *J. Savla, Center for Gerontology, Virginia Tech, Blacksburg, Virginia*

Discussant: *A. Davey, Temple University, Philadelphia, Pennsylvania*

Families provide support for more older adults in need of care than ever before, and they provide it for longer periods of time. However, most of our research on caregiving relies on normative characterizations and is often devoid of contextual considerations. The presentations in this symposium bring rich qualitative investigations and nationally representative databases in order to expand our paradigms of care and support. Along the way, they reveal some of the challenges families face and lessons to take caregiving research to the next level. Brossoie, Roberto and Blieszner dismantle the popular imagery of the sources of support for African-American caregivers and provide recommendations for improved sensitivity in the context of the needs and perceptions of available support. Takagi and Davey present a profile of caregivers for the oldest-old, the fastest growing, yet under-studied group, coordinating care in tandem with informal and formal support systems. Dolbin-MacNab's paper discusses the emerging area of grandchildren proving care to their custodial grandparents. Savla and Almeida consider care from the context of adult children providing routine assistance and long-distance support with an emphasis on short-term and long-term consequences for caregiver health. Finally, Roberto and colleagues triangulate data from multiple family members in order to evaluate care needs and daily challenges faced by families providing care to a person with mild cognitive impairment. Davey concludes the session with a critique and integrative discussion focusing on the promises and challenges of caregiving contexts in order to expand the paradigms of care and support.

### SOURCES OF SUPPORT FOR AFRICAN AMERICAN CARE PARTNERS OF PERSONS WITH MILD COGNITIVE IMPAIRMENT

N. Brossoie, K.A. Roberto, R. Blieszner, *Center for Gerontology, Virginia Polytechnic Institute and State University, Blacksburg, Virginia*

Popular imagery and many studies hold that most African American caregivers seek support from their church, family, and friends. However, few studies point out barriers to receiving these supports. We investigated family dynamics and support among primary supporters of older adults diagnosed with mild cognitive impairment (MCI). Twenty two African American primary care partners were interviewed about their interactions with the older adult with MCI and the physical and social support they received or desired from family members, friends, and community members. Findings indicate that the relationship between the primary care partner and the elder, age, income, family involvement, and perceived support are related to the types of emotional and physical support received. Reliance on church for support is constrained by willingness to let others see them as vulnerable and in declining health. Implications and recommendations for improved sensitivity to the needs and perceptions of available support will be discussed.

### CAREGIVERS FOR THE OLDEST OLD: A NATIONAL PROFILE

E. Takagi[1], A. Davey[2], D. Wagner[1], *1. Health Science, Towson University, Towson, Virginia, 2. Temple University, Philadelphia, Pennsylvania*

Population aging has been most pronounced among the oldest old (85+), the group most likely to be in need of care for their functional and cognitive limitations. We used data from 1,923 caregivers and 3,320 care recipients with at least one functional limitation from the 2004 National Long-Term Care Survey. Care recipients over 85 were: more likely to have IADL and ADL limitations, less likely to be married, and more likely to be women and live alone. Those caring for individuals 85+ were: more likely to report being nonwhite, in better health, to be women, adult children, and a sole caregiver. They were also more likely to receive informal and formal supports. We consider the potential of using formal services as effect modifiers for the association between primary objective stressors and physical, emotional, and financial strains. Implications for policy and practice are considered.

### GRANDCHILDREN AS CAREGIVERS FOR THEIR CUSTODIAL GRANDMOTHERS: WHO ARE THEY AND HOW ARE THEY DOING?

M.L. Dolbin-MacNab, *Human Development, Virginia Polytechnic Institute and State University, Blacksburg, Virginia*

Caregiving research has provided valuable insight into the needs and experiences of family caregivers. However, one population of caregivers that is not well-understood is grandchildren who provide care to their custodial grandparents. Using survey data from 81 adolescents and their custodial grandmothers, this study examined the extent to which grandchildren provide IADL and ADL care for their grandmothers, the association between caregiving and grandchild well-being, and grandchildren's perceptions of the impact of their caregiving responsibilities on their lives. Results indicate that the majority of grandchildren were involved in IADL activities and that older, Caucasian grandchildren were most likely to be involved in ADL activities. Greater involvement with ADLs was associated with higher levels of grandchild behavior problems. Grandchildren with borderline or clinical levels of behavior problems reported more negative impacts of caregiving, although ADL caregiving was associated more positive self-perceptions. These findings provide important guidance for future research and intervention.

### DAILY ROUTINE ASSISTANCE AND LONG-DISTANCE SUPPORT: SHORT TERM AND LONG-TERM IMPACT ON ADULT CHILDREN'S HEALTH

J. Savla[1], D. Almeida[2], *1. Center for Gerontology, Virginia Tech, Blacksburg, Virginia, 2. Pennsylvania State University, University Park, Pennsylvania*

Although caregivers enact care roles in a range of situations, yet a preponderance of research focuses on continuous and intense caregiving to a chronically ill family member and much less attention is paid to the casual routine assistance to family members. We use diary data from 119 adult children from Wave 1 and 239 adult children from Wave 2 of the National Study of Daily Experiences, to examine the association of providing routine assistance to older parents amidst everyday circumstances and the short-term and long-term physical and psychological consequences for adult children providing assistance. Even after controlling for within-person daily situational factors and between-person stable characteristics, the enactment of this role in itself was found to have immediate consequences on daily health for adult children providing care, particularly for those with fewer resources and more demands on time. Stability of these consequences was assessed using the second burst of diaries.

### THREE VOICES ARE BETTER THAN ONE: FAMILY MEMBERS' ASSESSMENT OF COGNITIVE DEFICITS IN LATE LIFE

K.A. Roberto, R. Blieszner, M.C. McPherson, *Virginia Polytechnic Institute and State University - Center for Gerontology, Blacksburg, Virginia*

We examined subjective perceptions of memory loss among older adults diagnosed with mild cognitive impairment (MCI) and two family members. Interviews with 92 triads revealed divergent perspectives on the degree of memory loss and the effects of MCI on everyday functioning. Elders with MCI and non-resident relatives typically reported few deficits in the elder's memory while those living with the elder offered extensive examples of deficits in the elders' cognitive abilities. Interviewing three family members increased insights into the complexities associated with MCI and uncovered nuances about their lives that would have been less likely to emerge from interviews with just one member. Family-level investigations are important for furthering understanding of the daily challenges facing families in this early stage of memory loss; however, recruiting families and analyzing dyadic and triadic data presented methodological challenges that need to be addressed as scholars expand paradigms used in studies of late-life families.

## SESSION 475 (SYMPOSIUM)

### INNOVATIVE APPROACHES TO GERONTOLOGICAL EDUCATION: LESSONS LEARNED INSIDE AND OUTSIDE OF THE CLASSROOM

Chair: *K.E. Cichy, Human Development & Family Studies, Kent State University, Kent, Ohio*

Co-Chair: *G. Smith, Human Development & Family Studies, Kent State University, Kent, Ohio*

Discussant: *S. Kunkel, Miami University, Oxford, Ohio*

Studying gerontology encourages students to explore their feelings about being members of an aging society and to think more deeply about their own aging. Courses are intended to challenge students' myths and stereotypes about aging and to increase students' understanding of the realities of the aging process as well as the diverse experiences of older adults. Gerontological education also prepares the future leaders within the field who will respond to the needs of an aging population and shape the future of aging policies. This symposium highlights innovative approaches to gerontological education that are being implemented both in and outside of the classroom. The first two presentations describe classroom approaches that encourage students to gain knowledge and question their own belief systems. Cichy & Smith will describe how college students and older adults both benefit from participating in intergenerational discussion groups as part of an introductory gerontology course. Whitbourne & Freeman will discuss the impact of coursework and service learning on students' behaviors and attitudes toward older adults. The remaining presentations describe approaches to gerontological education that go beyond the classroom environment to prepare students to be leaders in the field of gerontology. Greenfield will describe a guided study abroad aging program that offered students the opportunity to learn about systems of care in Israel. Finally, Van Dussen, Falkenberg, & Franklin will discuss the barriers to employment for graduates of gerontology programs as well as ways to overcome these barriers. The discussant, Suzanne Kunkel, will offer insights into these approaches.

### BRIDGING THE GENERATION GAP: BRINGING TOGETHER UNDERGRADUATE STUDENTS AND OLDER ADULTS TO BENEFIT BOTH GENERATIONS

K.E. Cichy, G. Smith, *Human Development & Family Studies, Kent State University, Kent, Ohio*

Designing class activities that enable students to interact with older adults in meaningful ways is one of the most powerful tools of undergraduate gerontological education. This paper describes the benefits of participating in intergenerational discussion groups for undergraduate students and older adults. Throughout the semester, older adults attended 4-5 Introduction to Gerontology class sessions, where together with the undergraduate students they participated in thought provoking dialogues about current gerontological issues. The goal was for older adults and college students alike to gain knowledge, improve problem solving skills, and question their own belief systems. After participating in the intergenerational discussions students reported significantly less ageist attitudes as measured by the Fraboni Ageism Scale compared to a control group of students. Further, older adults' self-report questionnaires and focus group participation indicated that attending the groups helped them feel mentally sharp and more knowledgeable about aging. Benefits for both generations will be discussed.

### SOME OF MY BEST FRIENDS ARE OLD: IMPACT OF COURSEWORK AND SERVICE LEARNING ON AGEISM

S.K. Whitbourne, G.P. Freeman, *University of Massachusetts Amherst, Amherst, Massachusetts*

An ageism scale developed with behavioral items assessed changes in behaviors and attitudes towards older adults through a Psychology of Aging course. Changes were assessed in scores for the class as a whole and for 13 students who participated in service learning. The pre-test was completed by 138 (99 females) undergraduates; initial scores revealed low ageist behaviors overall, however, certain items had elevated means indicating that the students believe older adults prefer to be younger, should not hold positions of responsibility after age 70, and typically live in the past. Previous studies employing similar methods failed to detect changes in attitudes because students who take these classes are self-selected to have more positive feelings toward older adults. By using a scale based on behaviors, greater sensitivity to interventions through coursework can be detected and recommendations can be made for using these experiences, particularly service learning, to help foster such interventions.

### STUDY ABROAD AS A STRATEGY FOR DEVELOPING LEADERS FOR THE FIELD OF AGING

E.A. Greenfield, *School of Social Work, Rutgers, The State University of New Jersey, New Brunswick, NJ*

There is increasing emphasis on the need for leaders within the field of aging who will help to bring about comprehensive changes in systems of care for older adults and their families. This paper addresses study abroad as one strategy through which higher education can promote leadership development among emerging cohorts of professionals. Study abroad provides students with first-hand experiences of systems of care that are similar and different to those in their home country. These experiences can help students to develop a better understanding of how socio- historical, cultural, and institutional factors fundamentally shape individual and population aging, and this understanding can powerfully contribute to students' leadership development. A guided study program in aging that took place in partnership between Rutgers University in New Jersey and Ben Gurion University in Beer-Sheva, Israel, provides insights regarding ways in which this theoretical model can be implemented in educational practice.

### OPPORTUNITIES AND BARRIERS TO EMPLOYMENT OF GERONTOLOGY STUDENTS IN THE AGING NETWORK

D.J. Van Dussen, H.M. Franklin, *Sociology, Anthropology, and Gerontology, Youngstown State University, Youngstown, Ohio*

Despite calls for increasing the number educated professionals with gerontological education in the aging network, many barriers to employment for graduates of our gerontology programs exist. Data from a sample of students in gerontology from a round table discussion at a state level conference and a paper and pencil survey of 89 professionals in aging indicated that employers want more employees with gerontological education which include internships in aging related workplaces and continuing education of existing workforce in gerontology. Barriers include time, the slow reaction of some employers within the aging network to include gerontology degrees as requirements, and limited job opportunities due to the Great Recession. The implications of the current research include policy changes in job descriptions, working with accreditation bodies, and educating employers about the unique and valuable knowledge provided by gerontology programs.

## SESSION 480 (PAPER)

## INTERGENERATIONAL RELATIONSHIPS: SOLIDARITY AND ESTRANGEMENT

### STRETCHING THE TIES THAT BIND: WHEN CHILDREN BECOME ESTRANGED FROM THEIR MOTHERS

M.M. Gilligan[1], J. Suitor[1], K. Pillemer[2], *1. Sociology, Purdue University, West Lafayette, Indiana, 2. Cornell University, Ithaca, New York*

Patterns of interaction between parents and adult children have been a major focus of research on later-life families for more than five decades. However, this line of work has explored interaction patterns that fall within the normative range of contact; virtually no attention has been directed toward understanding the circumstances that lead some parents and adult children to become estranged. In this paper, we use a combination of quantitative and qualitative data collected from 557 mothers about each of their adult children (n = 2,071) from the "Within-Family Differences Study" to explain patterns of estrangement between mothers and children. Two sets of factors that were expected to play central roles in estrangement were similarity and children's nonnormative behaviors. Preliminary results provided partial support for these hypotheses. Estrangement was least common among dyads in which the mother believed that she and the child shared the same values. However, contrary to homophily theories, daughters were more likely to become estranged than were sons. Also counter to expectations, children's nonnormative behaviors did not predict estrangement uniformly. Deviant behaviors were important only when they violated the mothers' normative expectations, regardless of whether those expectations matched broader societal norms. Theoretical and practical implications of these findings are discussed.

### PATTERNS OF EMOTIONAL RELATIONS AND INTERGENERATIONAL SUPPORT IN FAMILIES: A THREE-GENERATION-PERSPECTIVE

I. Albert, T. Michels, D. Ferring, *University of Luxembourg, Walferdange, Luxembourg*

Along with socio-demographic changes regarding increasing life expectancies and lower fertility rates, members of different generations within the family spend more and more life time together. This may provide new challenges for the regulation of intergenerational family relations as the needs and tasks of family members change over time. Referring to theoretical models of intergenerational solidarity, the present study aims to examine patterns of emotional relationship quality and exchange of functional support in three family generations. More precisely, different solidarity patterns are identified and their occurrences are compared between generations. A sample of 55 three-generation families (adolescent daughters, mothers, and grandmothers) from Luxembourg and Germany was studied by means of a standardized questionnaire measuring emotional relationship quality, perceived support provision and reception as well as family values. Drawing on notions of a leniency or an intergenerational stake effect, it was studied if a) older generations rate aspects of intergenerational solidarity more positively, and if b) support provision by older generations is less dependent on relationship quality compared to younger generations. Results are discussed with respect to intrafamilial processes underlying the regulation of intergenerational relations. Furthermore, norms with regard to the family are taken into account in order to explain simultaneous occurrences of a negative affectual relationship quality with high functional support. The paper will elaborate and explain different aspects of intergenerational solidarity and it discusses the implications of different patterns of solidarity in three generational families.

### INTERGENERATIONAL SOLIDARITY FROM 1971 TO 2005: A GENERATIONAL SEQUENTIAL DESIGN

L. Baker, M. Silverstein, *Andrus Gerontology Center, University of Southern California, Los Angeles, California*

This study examines adult children's reports of intergenerational solidarity with their mother over more than 30 years in order to address two research questions. First, how does the quality of intergenerational relationships change over the lifespan? Second, does the quality of intergenerational relationships differ by historical time? Data are taken from the Longitudinal Study of Generations (LSOG), a survey of four generations conducted from 1971-2005. We limit our analysis to two generations - G2 respondents who averaged 44 years of age in 1971 and their G3 children who reached the age of their parents between 1991 and 2005. Using data from eight waves of the LSOG, we assess growth curves in affectual solidarity over time, concatenating generations to form a synthetic cohort. G2s and G3s are "centered" by the time at which G3 children most closely matched the age of their parents. Results suggest that intergenerational solidarity declined over time for both generations. Further, affectual solidarity with adult parents was higher for the generation of adult children in 1971 as compared to their age-matched adult children in the 1990s/2000s. Implications of these results, as well as possible explanations for these changes will be discussed.

### CONTINUITY AND CHANGE IN INTERGENERATIONAL FAMILY RELATIONSHIPS

P.A. Dykstra, N. Schenk, *Sociology, Erasmus University Rotterdam, Rotterdam, Netherlands*

Using data from Wave 1 (2003-2004) and Wave 2 (2006-2007) of the Netherlands Kinship Panel Study (NKPS), we examine shifts in solidarity, conflict and ambivalence in over 5000 adult child-parent relationships. Our theoretical point of departure is that relationships change in response to changes in the lives of the parties involved and are shaped over the course of ongoing negotiations over demands, obligations, normative expectations, and time schedules. In both waves, the same general typology of adult child-parent relationships emerged. The typology is robust across dyads varying by gender composition and age. The five types are harmonious (akin to relationships with friends), ambivalent (intensive exchange of practical support accompanied by strain), obligatory (just keeping in touch), affective (emotionally supportive with few other meaningful exchanges), and discordant (predominantly negative engagement). Ambivalent ties are particularly likely to shift type (e.g. to harmonious or to discordant) which is consistent with the notion that they are under constant negotiation. The kind of shift is governed by escape options, such as the ability to defer responsibilities to other family members (geographic proximity, number of siblings), normative obligations to care (gender of the adult child), and dependence (stage of the life course). Harmonious ties show fewest shifts over time. Shifts in affective ties (e.g. to harmonious or to discordant) or in discordant ties (e.g. to ambivalent or to harmonious) are largely structured by biographical changes such as divorce, residential moves, and the arrival of grandchildren.

# SESSION 485 (POSTER)

## MENTAL HEALTH ISSUES

### EFFECTS OF INDIVIDUAL DIFFERENCE VARIABLES ON REACTIONS TO MENTALLY ILL OLDER ADULTS

A. Webb, J.M. Jacobs-Lawson, *University of Kentucky, Lexington, Kentucky*

Stigma has a negative impact on the quality of life of mentally ill older adults. The purpose of this study was to determine how individual difference variables influence perceptions of and reactions to mentally ill older adults, in an effort to reduce stigma. Participants (N = 276, aged 19-88 years, M age = 49.88) were presented with four vignettes depicting older men and women with one of four mental illnesses. In response to each vignette, participants indicated their (a) perceptions of the individual (i.e., how dangerous, dependent, and responsible the mentally ill older adult was), (b) emotional responses (how much pity, fear and anger they felt toward the person), and (c) behavioral reactions (their willingness to help and interact with the mentally ill older adult). Participants also responded to questions that assessed their knowledge of mental illness in old age. Results indicated that self-rated knowledge was associated with more positive perceptions and reactions toward mentally ill older adults, and that compared to men, women expressed less anger toward and more desire to help mentally ill older adults. Level of education and actual objective knowledge also had some effect on perceptions and reactions. These findings indicate that individuals' personal characteristics influence whether and how they stigmatize mentally ill older adults. This suggests that targeting educational efforts toward certain groups of individuals, such as men and those with low knowledge of mental illness in old age, may help reduce stigma against mentally ill older adults.

### THE IMPACT OF RELIGIOUSNESS/SPIRITUALITY AND SOCIAL SUPPORT ON DEPRESSION AND LIFE SATISFACTION AMONG ELDERLY KOREAN IMMIGRANTS

S. Roh, *Social Work, New York University, Woodside, New York*

Aim of study: The present study examined the relationships between religious experience, spiritual practice, and social support to depression and life satisfaction among elderly Korean immigrants, ages 65 to 89 years, in the New York City metropolitan area. Method: The study utilizes a cross-sectional survey design. Through face-to-face interviews, two hundred participants, 115 male and 85 female, were recruited from Korean senior centers in the New York City metropolitan area. The Brief Multidimensional Measures of Religiousness/Spirituality (BMMRS) was employed to measure various domains of religiousness/spirituality, including daily spiritual experiences, values/beliefs, forgiveness, private religious practice, religious/spiritual coping, and religious support. The Lubben Social Network Scale-Revised (LSNS-R) was used to measure a broad range of social support. Depression was assessed with the Geriatric Depression Scale-30 Korean version (GDS-K). The Satisfaction with Life Scale (SWLS) (Diener, Emmons, Larsen, & Griffin, 1985) was used to measure life satisfaction. Results: Multivariate analyses found that social support is related to higher life satisfaction, while religiousness/spirituality is associated with decreased depression, after controlling for demographic variables. In addition, social support is related to lower depression. Conclusion: Results from this study can help geriatric mental health professionals, healthcare providers and social work practitioners to better understand the adjustment processes of elderly Korean immigrants in order to develop culturally appropriate interventions and programs.

### COHORT DIFFERENCES IN MENTAL HEALTH AND PERCEIVED ECONOMIC STATUS: FINDINGS FROM THE GEORGIA CENTENARIAN STUDY

J. Cho[1], P. Martin[1], M. MacDonald[2], M. Johnson[3], L. Poon[3], *1. Iowa State University, Aems, Iowa, 2. Kansas State University, Manhattan, Kansas, 3. University of Georgia, Athens, Georgia*

The purpose of this study was to examine cohort differences in levels of mental health for 211 community-dwelling centenarians (whose Mini Mental Status Examination score was over 21) of Phase I and III of the Georgia Centenarian Study. The early cohort was defined as the one born between 1881 to 1895 and the later cohort included those born between 1896 to 1906. Six measures were used for comparison; the Life Satisfaction Index, the Geriatric Depression Scale, the Bradburn Affect Balance Scale (i.e., positive and negative affect), the Perceived Economic Status Scale from the OARS and the SPMSQ (Short Portable Mental Status Questionnaire). Result showed that there were significant cohort differences in five measures: life satisfaction, $M = -.13$ for the early cohort and $M = 2.25$ for later cohort; depression, $M = 3.95$ for the early cohort and $M = 2.21$ for the later cohort, $F(1,194) = 37.10$, $p < .001$; positive affect, $M = 12.41$ for the early cohort and $M = 11.63$ for the late cohort, $F(1,191) = 3.06$, $p = .08$; negative affect, $M = 8.20$ for the early cohort and $M = 6.39$ for the later cohort, $F(1,202) = 21.74$, $p < .001$; and perceived economic status, $M = 5.26$ for the early cohort and $M = 5.77$ for the late cohort, $F(1,174) = 9.38$, $p = .003$. This result suggests that the later cohort was more satisfied with life, felt less depressed, showed less positive or negative emotion, and had higher scores on perceived economic status when compared to the early cohort. In conclusion, cohort effect should be considered when studying centenarians.

### PSYCHOMETRIC PROPERTIES OF THE COPE SCALE IN OLDER ADULTS

M. Marty, D.L. Segal, *Psychology Department, University of Colorado at Colorado Springs, Colorado Springs, Colorado*

Researchers have encountered a number of difficulties with the measurement of coping in general (Coyne & Gottleib, 2006; Parker & Endler, 1992) and most coping scales lack sufficient validation among older adults. This study explored the reliability and validity of the Coping Orientation to Problems Experienced (COPE) scale among community-dwelling older adults. Participants (N = 109, M age = 71.4, SD = 8.2, range: 60–95 years) completed the COPE Scale (a dispositional measure of coping), NEO-Five Factor Inventory (measure of personality traits), Dysfunctional Attitudes Scale (measure of attitudes that predispose individuals to depression), and Geriatric Hopelessness Scale (measure of pessimism and hopelessness). Internal consistency (Cronbach's alpha) values were .88 for the problem-focused coping cluster, .85 for the emotion-focused coping cluster, and .77 for the dysfunctional coping cluster. Correlational analysis revealed positive relationships between problem-focused coping and extraversion (r = .33), agreeableness (r = .27), and conscientiousness (r = .39), and a negative relationship with neuroticism (r = -.31). Emotion-focused coping had positive correlations with extraversion (r = .39) and agreeableness (r = .34), and a negative correlation with hopelessness (r = -.54). Dysfunctional coping had positive relationships with neuroticism (r = .60) and dysfunctional attitudes (r = .35) but a weak nonsignificant relationship with hopelessness. Results indicate the COPE has strong internal consistency in the current sample and correlations were in the expected directions, providing modest evidence of convergent validity. Further validation of the COPE among older adults should include more diverse samples and factor analysis of underlying factors.

## DIRECT AND INDIRECT EFFECTS OF HEARING LOSS ON MENTAL HEALTH IN OLDER ADULTS

Y. Ishioka, Y. Gondo, I. Kurokawa, N. Renge, M. Kawasaki, *Osaka university, Suita, Japan*

Introduction Many studies demonstrated that age-related hearing loss can lead to diminished mental health. But our understanding of the process is limited. The purpose of this study was to examine direct and indirect effects on mental health of hearing loss in older adults. Methods Participants were 98 healthy community-dwelling older adults. The mean age of the sample was 67.4 years; the range was 60 to 85 years. 61.2% of the sample participants were female. Hearing losses were assessed by subjective and objective measurements. Subjective measurement was evaluated with the 3 questions with 4 response categories. As objective measurement, pure-tone threshold screening was conducted with an audiometer. The average hearing level was defined as the average of the participant's hearing thresholds at 500, 1000, and 2000 Hz for the better ear. In addition to sociological background of age, sex, and education, we also measured amount of chronic disease, self-rated health, 5 dimensions of personality traits, participation in learning and educational activities as social activities, and WHO-5 well-being index as mental health. Result We conducted a path analysis to test a model incorporating subjective and objective hearing losses and social activities as predictors of mental health. The result indicated that subjective hearing loss indirectly influenced mental health through social activities, while subjective and objective hearing losses were not related to mental health directly. Conclusion Subjective hearing loss is indirectly associated with reduced mental health in older adults.

## GENDER DIFFERENCE IN THE LONGITUDINAL RELATIONSHIPS BETWEEN DRINKING BEHAVIOR AND DEPRESSION FROM MIDDLE-AGED TO OLDER ADULTS

O. Baik, K.J. Farkas, *Mandel School of Applied Social Sciences, Case Western Reserve University, Cleveland, Ohio*

There is a special need to understand not only the co-variation of alcohol use, alcohol-related problems and depression, but also how the relationships change over time from mid life to later life. The aim of the present study was to clarify and extend previous studies by examining gender differences in the relationships among alcohol consumption, alcohol-related problems, and depression from middle-aged to older adults. The two-wave of Wisconsin Longitudinal Study collected in 1993-1994 and 2003-2005 were used for this study. For analyzing longitudinal relations, multivariate model by logistic regression was tested, while controlling for prior depressive symptoms, socioeconomic and health variables. For only males, after controlling for all other possible confounders and prior depressive symptoms, problem drinking at baseline was inversely associated with depressive symptoms at follow-up (OR = 1.367, 95% CI: 1.008-1.854). For females, there were no statistically significant relationships between alcohol consumption or drinking problems and subsequent depression. These results support the hypothesis of this study that for males, alcohol problems predicted subsequent depressive symptoms unlike females. Conversely, baseline depressive symptoms significantly predicted later drinking problems for both gender (OR = 1.726, 95% CI: 1.304-2.285 for males, OR = 1.892, 95% CI: 1.347-2.657 for females, p<.001). The results indicate that developing drinking problems from mid-life through later life are crucial factors in the development of later life depressive symptoms. Future research examining the mechanisms behind these findings would be useful in developing effective prevention and treatment programs for this population with depression and/or alcohol use-related problems.

## VASCULAR HEALTH AND ACTIVITY LEVEL: UNIQUE PATHWAYS TO ANXIETY AND DEPRESSION

A. Mueller, K. Kane, L. King, B. Yochim, *University of Colorado at Colorado Springs, Colorado Springs, Colorado*

Introduction: This study examined cerebrovascular risk factors (CVRFs), non-vascular medical conditions (e.g., arthritis), activity level, and depressive and anxiety symptoms in older adults at baseline and 15-month follow-up. Method: Community-dwelling older adults (N = 110) self-reported CVRFs and other medical problems, and were administered the Florida Cognitive Activity Scale (FCAS), Geriatric Anxiety Scale (GAS), and the Geriatric Depression Scale (GDS). Participants (N = 67) returned for follow-up assessments at 15 months. Results: At baseline, CVRFs significantly predicted higher GDS scores, $\beta = .24$, $p < .05$, and GAS scores, $\beta = .23$, $p < .05$. FCAS total score significantly predicted lower GDS scores, $\beta = -.28$, $p < .05$, but not GAS scores. CVRFs did not predict FCAS total. Non-vascular conditions predicted GAS total, $\beta = .21$, $p < .05$, but not GDS scores. CVRFs at baseline were significantly correlated with follow-up GAS, r = .40, and GDS, r = .33, $p < .05$. Discussion: Baseline data indicates differential relationships exist among activity, vascular health, depression, and anxiety. Longitudinal data support the vascular depression hypothesis and extends the hypothesis to anxiety. More data will be collected to examine the longitudinal relationship between depressive symptoms and activity. Given these findings, prevention and treatment of CVRFs may be effective interventions in treating late life anxiety and depression, and engagement in valued activities may improve depressive symptoms more than anxiety symptoms.

## SHARED PERCEPTIONS AND DIVERGENT SOCIAL EXPERIENCES OF COUNSELING AMONG AFRICAN AMERICAN AND WHITE OLDER ADULTS

J. Joo[1], M. Wittink[2], *1. Department of Psychiatry, University of Pennsylvania, Philadelphia, Pennsylvania, 2. Department of Family Medicine and Community Health, University of Pennsylvania, Philadelphia, Pennsylvania*

Despite evidence that suggests that older adults, and African American older adults in particular, prefer counseling over medications for treatment of depression, few older adults use such psychological treatments. In this study, we explore attitudes, beliefs and experiences of counseling in order to illuminate factors which may contribute to low counseling and psychotherapy use for depression care among African American and White older adults. We used a grounded theory approach to analyze semi-structured interviews with older African American and white older adults from primary care, comparing African American and White respondents to identify similarities and differences. Our analysis suggested that older adults believe in the usefulness of counseling based on a strong belief in the value of talking about emotional problems; however, they may not use counseling due to a reluctance to talk about emotional problems with professionals, whom they may not trust. We also found that African American men were a subgroup among older adults who were least familiar with counseling as a treatment for depression. Finally, African American older adults did not mention use or influence of their social relationships when talking about depression and depression care whereas white older adults described various ways in which their personal relationships influenced their perceptions of counseling or helped them navigate available counseling services. Given the proven efficacy of psychological treatments and the preference for counseling and psychotherapy among older adults, psychosocial interventions which address conceptual barriers, lack of familiarity about services and incorporate the lived social experience of depression are needed to increase acceptability and use.

### PRELIMINARY VALIDATION OF A PROFESSIONAL GEROPSYCHOLOGY COMPETENCIES ASSESSMENT TOOL

M. Karel[2], C. Holley[3], S.K. Whitbourne[4], D.L. Segal[1], *1. University of Colorado at Colorado Springs, Colorado Springs, Colorado, 2. Psychology Service, VA Boston Healthcare System, Brockton, Massachusetts, 3. Stratton VA Medical Center, Albany, New York, 4. University of Massachusetts Amherst, Amherst, Massachusetts*

Based on competencies outlined in the Pikes Peak Model for Geropsychology Training (Knight, Karel, Hinrichsen, Qualls, & Duffy, 2009), a workgroup of the Council of Professional Geropsychology Training Programs (CoPGTP) recently developed a competency assessment instrument called the Pikes Peak Geropsychology Knowledge and Skill Assessment Tool (Karel et al., 2010). This assessment tool is designed to help psychologists and trainees identify relative strengths and weaknesses in order to inform geropsychology training goals. The present study evaluated group differences on the nine competency domain subscales in a sample of self-identified geropsychology professionals and graduate students. The full sample (N = 120) consisted of 85 professionals and 35 graduate students who completed the tool via an online survey. Results indicated that professionals reported significantly greater self-rated levels of competence than students on all subscales (all t-scores > 8.97, p< .01). Among professionals, the number of geropsychology training experiences (e.g., specialized internship, postdoctoral training, CE workshops) was significantly and positively related to perceived competence in all knowledge and skill domains (correlations ranging from .29 to .53, p<.01). Likewise, for students, the number of training experiences was significantly and positively related to perceived competence in all domains (correlations ranging from .35 to .60, p < .05). Of note, number of training experiences was more closely related to perceived competence than simply years in practice or, for students, years in training. Ongoing research is warranted to continue to develop and refine the tool.

### PREVENTABLE HOSPITALIZATIONS AMONG ASSISTED LIVING AND NURSING HOME RESIDENTS

M.A. Becker, T. Boaz, R. Andel, J. DiGennaro, *Aging & Mental Health Disparities, University of South Florida, Tampa, Florida*

Preventable hospitalizations place an enormous burden on an already overtaxed healthcare system. There is growing interest in reducing hospitalizations for ambulatory care-sensitive (ACS) conditions, which by definition can be treated safely in non-hospital settings. There has been little research comparing ACS hospitalizations among assisted living facility(ALF) and nursing home (NH) residents. This study compared the prevalence rates and risk factors among Medicaid-enrolled ALf and NH residents in Florida. We analyzed data for 72,251 NH and 16,208 ALF residents. Approximately 11% of the NH population (8,382 residents) and 16% of the ALF population (2,587 residents) were hospitalized for an ACS condition. ACS hospitalizations accounted for 18.2% of all hospitalizations among nursing home residents and 17% among assisted living residents. Among NH residents, younger age, non-White race, serious mental disorder, dementia, alcohol and drug use, and co-morbidity were all independently associated with a greater risk of ACS hospitalization (p<.05). Among AL residents, older age, non-White race, and co-morbidity were associated with greater risk of ACS hospitalization, whereas dementia and psychotic disorder were associated with reduced risk (p<.05). We also found that being in an ALF as opposed to NH was associated with a 43% greater risk of ACS hospitalization (p<.001). The availability of 24-hour medical care in nursing homes may allow for earlier identification and appropriate treatment of ambulatory care-sensitive conditions, thus reducing the proportion of nursing home residents requiring hospitalization. Given the higher cost of acute medical care, reducing avoidable hospitalizations in these populations could result in substantial savings.

### PATHWAYS OF PHYSICAL AND MENTAL HEALTH IN OLD AGE: LONGITUDINAL FINDINGS FROM THE IGS AND THE NAS

C. Jones[1], A. Spiro[2], C.M. Aldwin[3], *1. California State University, Fresno, Fresno, California, 2. VA Boston Healthcare System, Boston, Massachusetts, 3. Oregon State University, Corvallis, Oregon*

While physical and mental health are positively associated (Aldwin et al., 2004), the ability to maintain good mental health in the face of declining physical health may be a resilience factor in optimal aging. Data from two longitudinal studies—the Intergenerational Studies (IGS; N=82; Mean age=83.4, SD=3.7, 51% men) and the Normative Aging Study (NAS; N=792; Mean age=65.1, SD=6.9; 100% men)—were used to examine the associations between changes in self-rated physical and self-rated mental health across 10 years (1993/6 – 2002/6). The SF-36 was used in the IGS, while the comparable Veterans Rand 36 (VR-36) was used in the NAS. In both samples, physical health was more stable than mental health, and the former was more likely to decline. Physical health seldom improved, but mental health sometimes did improve, despite declines in physical health. Those in poor mental health almost never reported good physical health. In the IGS, 70% of those with constant or declining physical health still showed good mental health in old age; this resilience was unrelated to gender or cohort. In the NAS, individuals with better mental health at baseline were most likely to improve in mental health. Assuming that this does not simply reflect reporting biases sometimes seen in very late life (Johnson & Barer, 1996), the processes through which older adults maintain or even improve their mental health despite physical declines should be a major focus in the study of optimal aging.

### WILLINGNESS TO USE MENTAL HEALTH SERVICES AMONG OLDER RESIDENTS IN ASSISTED LIVING

N. Park, Y. Jang, B. Lee, L. Schonfeld, V. Molinari, *University of South Florida, Tampa, Florida*

Purpose: Little is known about how AL residents perceive mental health services. The purposes of this study were (1) to examine residents' willingness to use mental health services and (2) to explore its predictors based on Anderson's health behavior model. Method: Data based on face-to-face interviews with a sample of 150 older residents from 17 AL settings in Florida were used in analyses (Mage = 82.8, SD = 9.4). Multivariate logistic regression estimated the likelihood of willingness to use mental health services in relation to predisposing (demographics and physical health), mental health needs (depressive symptoms), and enabling variables (social network, instrumental support, emotional support, informational support, satisfaction with support, and previous use of mental health services). Results: More than 27% of the sample fell within the category of probable depression measured by Geriatric Depression Scale-Short Form. Approximately 80% of the sample indicated willingness to use mental health services. In one model with only predisposing variables, older age and being married were associated with less willingness to use mental health services. In the final model, lower emotional support and higher informational support were found to predict greater willingness to use services. Implications: The direct link between informational support and higher willingness to use mental health services suggests that AL residents may benefit from education regarding interventions for late-life depression. Considering that late-life depression has debilitating effects, concerted efforts need to be made to identify and treat depression for the AL population.

### STYLE VS. SUBSTANCE: DIFFERENTIAL EFFECTS OF DISPOSITIONAL AND GOAL-SPECIFIC COPING ON MENTAL HEALTH

K. Boerner, *Jewish Home Lifecare/Mount Sinai School of Medicine, New York, New York*

When goal pursuit is challenged, adaptive coping responses can involve the persistent effort to change one's situation to reach the goal (assimilation) and, when this no longer seems viable, to adjust one's goals to what is feasible (accommodation; Brandtstädter, 1999). The present study examined the understudied topic of coping with chronic disability in middle adulthood. Participants were 216 adults aged 40-64 who experienced adult onset of vision loss. We conducted hierarchical regressions to assess the unique contributions of general and goal-specific assimilative and accommodative coping to explaining variance in depression, anxiety, and life satisfaction. General coping was assessed with a scale designed to measure dispositional assimilative and accommodative coping tendencies. Goal-specific coping was assessed with four coping questions that were asked in reference to specific goals reported by participants (e.g., assimilative: still working on or putting effort into this goal; accommodative: adjusting the goal or letting it go). The two indicators of goal-specific accommodative coping were entered separately, to examine adjusting and letting go of a goal as two facets of accommodative coping. Overall, general coping explained more variance in depression and anxiety than goal-specific coping, whereas both explained a similar amount of variance in life satisfaction. For all three outcomes, higher levels of general accommodative coping were linked to more positive adaptation. Differential findings emerged for goal-specific accommodative coping: goal adjustment was related to higher levels of distress, whereas letting go of a goal was related to greater life satisfaction. Implications for theory and future research are discussed.

## SESSION 490 (SYMPOSIUM)

### NOW YOU SEE IT, NOW YOU DON'T: MODERATORS OF THE POSITIVITY EFFECT

Chair: *T.M. Hess, North Carolina State University, Raleigh, North Carolina*
Discussant: *M. Mather, University of Southern California, Los Angeles, California*

Recent theoretical perspectives have suggested that old age is associated with an increasing emphasis on emotional goals. This developmental shift is reflected in regulatory processes designed to either maximize positive affect or minimize negative affect, manifested as a relative increase in a focus on positive versus negative information. Empirical support for this positivity effect is mixed, however, leading to questions regarding the factors moderating this effect. Empirical data relating to two specific questions are presented in this symposium. First, are there individual differences in factors supporting regulatory functions promoting the positivity effect in later life? Second, are there contextual factors that moderate the strength of the positivity effect? For example, do chronic emotion-focused goals in later life always lead to a focus on positive information? Following up on findings emphasizing the importance of cognitive control in emotion regulation, Allard and Isaacowitz demonstrate that there are conditions under which older adults exhibit positivity effects even when cognitive resources are occupied. Grühn examines the degree to which participant characteristics interact with task material in determining age-related patterns of memory for emotional material. Zhang, Fung, Li, and Isaacowitz present data suggesting that older adults may focus on less positive, but more realistic information to promote a positive self-image. Finally, Hess and Kotter-Grühn demonstrate that older adults are more sensitive to the information value of positive and negative information when making social judgments, focusing more on negative information when it is informative.

### MOTIVATIONAL PRIORITY AND COGNITIVE CONTROL EFFORT: MODERATORS OF OLDER ADULTS' POSITIVITY IN GAZE?

E.S. Allard, D. Isaacowitz, *Psychology, Brandeis University, Waltham, Massachusetts*

Previous findings suggest that cognitive control effort plays a significant moderating role in older adults' motivated preferences for positive relative to negative emotional stimuli. In two studies, older adults viewed a series of emotional-neutral images while their eyes were tracked. Cognitive control effort was manipulated by having participants view images while their attention was divided by a challenging short-term memory task (auditory n-back with 3-back lag in Study 1; tonal discrimination task in Study 2). In each study, there were conditions where older adults were instructed to focus on an emotion regulation goal. In these conditions older adults' were able to display fixation preferences toward positive and away from negative images; this was observed despite distraction from challenging secondary tasks in divided attention. These results indicate situations where positivity effects in older adults' emotional information processing may not necessitate full cognitive control effort.

### EMOTIONAL BIASES IN MEMORY: THE IMPACT OF MATERIAL AND INTERINDIVIDUAL DIFFERENCES

D. Grühn, *Psychology, NC State University, Raleigh, North Carolina*

Some authors suggest that older adults, relative to younger adults, focus more on positive than negative information. In memory studies for emotional material, the pattern of findings is, however, inconsistent. Some studies find this so-called positivity effect; some studies don't. In this paper, we are discussing two factors that may moderate a positivity effect: Person characteristics (e.g. current mood, emotion regulation) and material characteristics (e.g. arousal, imagery). In two memory studies (one with words and one with pictures as to-be-remembered material) with young and older adults, we investigated the independent and joined impact of these two factors in moderating age differences. The findings of both studies suggest that person characteristics had little impact on remembering emotional material. In contrast, material characteristics played a crucial role in explaining age differences. Findings are discussed in light of contextual accounts of human cognition and aging.

### HOW UNREALISTIC POSITIVE IMAGES OF AGING ATTRACT ATTENTION

X. Zhang[1], H. Fung[1], T. Li[1], D. Isaacowitz[2], *1. Chinese University of Hong Kong, Hong Kong, China, 2. Brandeis University, Boston, Massachusetts*

This study examined whether the positivity effect exists in attention toward images of aging. Sixteen sets of negative, neutral, positive and overly (i.e., unrealistically) positive images of aging were presented to younger, middle-age, and older Chinese. Each set of images was presented simultaneously. An eye tracker was used to record gaze time towards these images. Findings revealed that participants from all age groups paid more attention towards overly positive images compared with positive images. However, gaze time towards overly positive images was moderated by participants' realistic ratings of them, such that the more unrealistic an image, younger and middle-aged participants gazed at it more while older participants gazed at it less. These results suggested that older adults might selectively ignore unrealistically positive images of aging to maintain a positive self-image.

### ATTENTION TO POSITIVE VERSUS NEGATIVE SOCIAL INFORMATION: THE EFFECTS OF AGE, SITUATIONAL GOALS, AND DIAGNOSTICITY

T.M. Hess, D. Kotter-Gruehn, *North Carolina State University, Raleigh, North Carolina*

In certain social situations, negative information is more informative than is positive information. Thus, a focus on the latter might have long-term maladaptive consequences when, for example, choices of a social partner ignore diagnostic negative information. In this study, 150+ adults (ages 19-88) made either general evaluative judgments or judgments regarding attractiveness as a social or work partner based on behavioral descriptions of others. Consistent with past research, we observed an age-related increase in attention to trait-diagnostic information, regardless of valence. Older adults' use of such information in making trait inferences was also unaltered by situational goals. Finally, older adults' judgments regarding work and social partners were more likely to reflect the valence of the relevant diagnostic information for each judgment (e.g., negative moral-trait information for social partner). These results suggest that older adults are sensitive to specific contextual constraints and do not indiscriminately focus on positive information.

## SESSION 495 (PAPER)

## RECRUITMENT AND RETENTION OF RESEARCH PARTICIPANTS

### CHARACTERISTICS OF CAREGIVING FAMILIES WHO LEAVE AN EVIDENCE-BASED INTERVENTION REPLICATION

H. Menne[1], S. Bollin[2], D. Bass[1], J. Johnson[1], S. Ambro[1], *1. Margaret Blenkner Research Institute, Benjamin Rose Institute, Cleveland, Ohio, 2. Alzheimer's Association - Northwest Ohio Chapter, Toledo, Ohio*

Results of intervention studies highlight the improvements experienced by individuals or families completing an intervention; these results often serve as the basis for replication of an intervention or program. Less talked about are those families and individuals who begin but do not complete the intervention. Interestingly, information about intervention program "leavers" may be a better indicator of the generalizability of the program to a target population than outcomes for program "stayers." The evidence-based program, Reducing Disability in Alzheimer's Disease, is being replicated in Ohio with support from the Alzheimer's Disease Supportive Services Program of the Administration on Aging. Eight-five families started the 12-month Reducing Disability in Alzheimer's Disease program; however, 21 families left before completing the first 3 months of the program. In 15 of the 21 cases, the family left the program because of poor health of the person with dementia (including hospitalization, nursing home or assisted living placement, or hospice). To determine whether "stayers" and "leavers" differed at the start of the program, independent samples t-tests were conducted to assess difference on demographics, health, and functional ability. Results suggest poorer health for persons with dementia who left the program. For example there is a mean difference in depression levels for persons with dementia (t(47)=2.207, p=.06), and a mean difference in person with dementia's ability to balance on one leg (t(60)=-2.236, p=.03). A better understanding of program "leavers" may lead to enhanced recruitment processes, eligibility requirements, and program content that could result in few "leavers" in future replications.

### SHOULD I STAY OR SHOULD I GO NOW?: EXAMINING RESPONDENTS' CHARACTERISTICS REGARDING CONTINUOUS PARTICIPATION VERSUS ATTRITION IN A LONGITUDINAL PANEL STUDY

O. Hautz, S. Kunkel, *Sociology and Gerontology, Miami University, Oxford, Ohio*

The Ohio Longitudinal Study of Aging and Adaptation (OLSAA) started in 1975 and continued through 2005, covering a time span of 30 years. Originally designed as a biannual panel study, the OLSAA now consists of 7 waves of data collection (1975, 1977, 1979, 1981, 1991, 1995, 2005). The initial survey was sent to 1,805 individuals 50 years and older (representing the total population of people 50 years and older in a small Midwestern town) and resulted in a study population of 1,271 individuals (response rate 70.5%). Thirty years after the initial survey, 111 individuals were still participating in the OLSAA study, ranging in age from 85 to 100 (mean age 89.46) with fifty-two being male (46.8%) and 59 female (53.2). For this study, we examine differences and similarities between the group of individuals who continuously participated over the course of 30 years with those individuals who participated in Wave 1 and with those who dropped out due to mortality or other reasons (e.g., refusal to participate, moved to different location). The groups are compared regarding their gender, age, self- rated health, marital status, morale, life satisfaction, acceptance of stereotypes about aging, and goal orientation. Preliminary analyses show significant differences between those who participated in 2005 and those that dropped out at baseline (1975). For example, the findings show that the 2005 participants have significantly more years of education than the other two groups. Discussion focuses on the impact of attrition versus continuous participation in a longitudinal panel study.

### PHENOMENOLOGY- ENHANCED INTERVIEWING TECHNIQUES WITH PHONE CONFERENCING

J. White, S.J. Barthelmeus, *Capella University, Minneapolis, Minnesota*

Phenomenology is a qualitative process for researching lived experiences in order to gain an understanding of the essence of those subjective experiences. In order to explore and document their world, event, or phenomenon, researchers traditionally ask open-ended or broad semi-structured questions utilizing digital devices such as recorders and videos. Because the procedure is labor-intensive and involves a considerable amount of time, the participants for a recent rural grandfather study refused face-to-face interviews and requested instead telephonic interviews. To meet this challenge, the investigator developed an interview setting that allowed participants to participate via recorded and transcribed conference calls. This variation on the original proposed methodology enhanced the understanding of the rural grandfather experience by expanding geographical boundaries for recruitment, reduced experimenter effects, and provided anonymity for eliciting rich, candid responses. In addition, the conference call center provided a CD recording and transcription option, thereby streamlining the coding process. This telephonic methodology for phenomenological aging studies may be valuable for conducting grounded-theory studies using more structured interviewing techniques. After attending this activity, participants will be equipped to apply this methodology to phenomenological data collection.

### CHALLENGES IN RECRUITING DRIVERS WITH PARKINSON'S DISEASE FOR RESEARCH STUDIES

A. Crizzle[1], A. Myers[1], Q.J. Almeida[2], *1. Health Studies and Gerontology, University of Waterloo, Waterloo, Ontario, Canada, 2. Wilfrid Laurier University, Waterloo, Ontario, Canada*

Few driving studies, most with small samples, have been conducted on individuals with Parkinson's disease (PD). The present study is examining the impact of Parkinson's symptoms on comfort level and driving patterns, compared to healthy older drivers. The PD group is being recruited from a Movement Disorders Centre in Waterloo, Ontario. To determine study eligibility, a driving screening form is being administered to patients living in the region. Of the 97 patients screened to date, only 12% have been successfully recruited even after lowering the age criteria from 65+ to 55+. While recruitment to achieve our target of 40 PD drivers continues, a great deal is being learned in the process. Those screened to date range in age from 39 to 90 (mean 68.3 ± 10.1); 64% are men. Motor scores on the UPDRS (Unified PD Rating Scale) range from 8.5 to 68 (mean 30.3 ± 11.3). Although all had driven at some point, only 62% are currently driving. Compared to former drivers, current drivers are significantly younger (mean 66.3 ± 10.2 versus 72.2 ± 9.6, p <.05), less severe (mean UPDRS 27.2 ± 8.3 versus 38.1 ± 12.4, p <.001) and more likely to be taking dopamine agonists (DA) in comparison to levodopa (p<.01). Preliminary findings suggest that persons with PD may stop driving at an earlier age than the general population.

Not surprisingly, those who are still driving are fearful of being reported to licensing authorities, despite assurances to the contrary.

## SESSION 500 (PAPER)

## REDUCING DISABILITIES AND FALLS

### EFFECTIVENESS OF GARDENING ACTIVITIES ON IMPROVING OLDER ADULTS' GAIT AND BALANCE

T. Chen, M. Janke, *School of Aging Studies, University of South Florida, Tampa, Florida*

Falls are a common concern among older adults, and decreasing the incidence of falls among this population is considered a major public health concern due to the related financial and social burdens of fall-related injuries. Activities such as Tai Chi and yoga have been shown to be effective in improving gait and balance to reduce the incidence of falls in older adults. This study explores whether gardening, one of the most common physical activities among older adults, could serve a similar purpose and benefit older adults by improving gait speed and balance and consequently reduce their risk of falling. The data for this study comes from the Health and Retirement Study (HRS, 2006) and Consumption and Activities Mail Survey (CAMS, 2005). Our sample included 3237 adults age 65 and older, and was 46.8 % male and 84.8 % White. In this study, gardeners were defined as who gardened at least 25 minutes per week based on the definition of HRS. This resulted in a total of 742 gardeners and 595 non-gardeners. Independent t-tests, correlations, and regression analysis were conducted to analyze the relationship between gardening and health outcomes. Our findings indicate that gardeners reported significantly better balance and gait speed and had fewer chronic diseases and physical limitations than non-gardeners. Significantly fewer gardeners reported a fall in the past two years compared to the non-gardeners. Our findings suggest that gardening is associated with better balance and gait speed and may prove to be beneficial in future fall intervention programs.

### THE EFFECT OF COMMUNITY ACTIVITIES ON WALKING BEHAVIOR OVER FOUR YEARS AMONG THE OLDEST-OLD

J. Gaines, K. Marx, K.L. Burke, J.M. Parrish, *The Erickson Foundation, Baltimore, Maryland*

Leisure time physical activity among older adults has increased in the last ten years with walking as the preferred activity. However, many older adults continue to participate in less physical activity and/or less vigorously than is usually recommended. Within this longitudinal study, participants live in a CCRC physically designed to promote walking. Also, as part of the research study, participants are encouraged to walk. This report covers changes in walking activity over a four year period. At baseline, 364 older adults (mean age 81.04 (sd=5.9), 75% female) reported a mean of four chronic medical conditions. The total number of reported internal and external community activities was 8.0 (sd=2.7). After four years, data was available on 160 participants (44%). The mean age of the participants at Year 4 was 84.6 (sd=5.6). The number of chronic medical conditions had significantly increased to 4.48 (sd=2.1; t=-2.1, p=.04). There was a non-significant increase in the total number of community activities (8.9; sd=2.8). Walking activity was measured at baseline and Year 4 using a StepWatch™ over a three day period. The baseline mean step total was 8031.6 (sd=3460.0). At Year 4, there was a non-significant decline to 7784.0 (sd=3644.8; t=.76; p=.45). The results of a linear regression demonstrated that the combination of age (beta = -.30), total number of medical conditions (beta = -.25) and community activities (beta =.16) explained 22% of the variance in total step count. The promotion of participation in community activities may be a way to increase walking activity.

### CORE SELF-EVALUATION AS A NOVEL PREDICTOR OF STRENGTH TRAINING ADOPTION IN OLDER ADULTS

M.K. Baker[1], D.J. Kennedy[4], P.L. Bohle[4], M.A. Fiatarone Singh[1,2,3], *1. Exercise Health and Performance Research Group, The University of Sydney, Lidcombe, New South Wales, Australia, 2. Jean Mayer USDA Human Nutrition Research Centre on Aging at Tufts University, Boston, Massachusetts, 3. Hebrew SeniorLife, Harvard Medical School, Boston, Massachusetts, 4. Ageing and Human Development Research Group, The University of Sydney, Lidcombe, New South Wales, Australia*

Declining physical function is associated with morbidity and mortality. Progressive resistance training (PRT) counteracts sarcopenia and has been demonstrated to improve physical function and quality of life in older adults. Despite the clear benefits of PRT, participation remains low. Core self-evaluation (CSE) is a relatively new concept within the personality domain first introduced in the industrial-organizational literature by Judge et al. (1998). The core self-evaluation construct is theoretically antecedent to four traits: locus of control, self-esteem, neuroticism (emotional stability), and generalized self-efficacy. We have examined the association of CSE with exercise adoption among older adults invited to participate in a PRT trial. We hypothesized that CSE would positively predict adoption of PRT. METHOD All residents of two retirement communities were invited to complete questionnaires assessing demographics, physical activity, CSE, and general health. Following completion of questionnaires, residents were invited to take part in an on-site, 10-week randomized controlled trial of a PRT-based exercise trial. RESULTS 38 of 358 residents (63.2% women; 76.6±6.1 yr; range 58 to 92) enrolled, and 118 residents completed the questionnaires. Multiple regression analysis of predictors of adoption of PRT indicated that the demographic variables accounted for 38% of the variance. Inclusion of CSE ($\beta = .405$) accounted for an additional 10% of the variance in PRT adoption ($\Delta R2 = .10$, $p = .025$). DISCUSSION CSE was predictive of PRT adoption in this cohort, adding significantly to known demographic predictors. This is the first study to show that CSE may influence adoption of PRT in any cohort.

### SELF-EFFICACY AND NEIGHBORHOOD WALKING IN OLDER ADULTS WITH AND WITHOUT A HISTORY OF FALLING

N. Gallagher[1,2], K. Gretebeck[2], C. Loveland Cherry[2], D.L. Ronis[2,3], P. Clarke[4], *1. Michigan State University College of Nursing, East Lansing, Michigan, 2. University of Michigan School of Nursing, Ann Arbor, Michigan, 3. Department of Veterans Affairs, Ann Arbor, Michigan, 4. University of Michigan Institute for Social Research, Ann Arbor, Michigan*

Walking is an excellent form of physical activity (PA) for older adults (OA). Outdoor falls are more common in physically active OA, and OA who have fallen have lower PA self-efficacy. This cross-sectional study examined the association of self-efficacy (for walking duration, PA barriers, neighborhood barriers, gait and balance) with neighborhood walking in OA (n = 326, age 60-99 years, M =76.1, sd = 8.34) who had and had not fallen during the previous year. Multiple regression indicated that total self-efficacy explained 34.5% of the variance in neighborhood walking in fallers ($F(5,102) = 10.744$, $p < .001$); self-efficacy for PA barriers had the strongest influence ($\beta=.383$, $p < .001$) followed by self-efficacy for neighborhood barriers ($\beta = .199$, $p < .05$). For non-fallers, total self-efficacy explained 19.7% of the variance in neighborhood walking ($F(5, 208) = 10.237$, $p < .001$). Self-efficacy for PA barriers had the strongest influence ($\beta = .286$, $p < .001$) followed by self-efficacy for walking duration ($\beta = .186$, $p < .05$). Gait and balance self-efficacy were nonsignificant for both groups. Compared to non-fallers, fallers reported lower confidence performing PA when care-giving responsibilities ($t = 2.649$, $p < .01$) and balance problems ($t = 2.046$, $p < .05$) were present. Walking interventions tailored for fallers should address increasing self-efficacy in overcoming neighborhood barriers (e.g. lighting and safety) and PA barriers (e.g. health problems and caregiving responsibilities); for non-fallers, increasing confidence in walking for longer duration and overcoming PA barriers (e.g. health or balance problems).

## SESSION 505 (PAPER)

## SOCIAL ACTIVITY AND SOCIAL NETWORKS

### HOW IS SOCIAL ACTIVITY INVOLVEMENT EXPLAINED BY DEMOGRAPHIC AND SOCIOECONOMIC CHARACTERISTICS AMONG THE POPULATION AGED 45 AND OLDER IN CHINA?-AN EXPLORATORY STUDY OF CHARLS-PILOT

J.J. Liang, *MU,Ohio, Oxford, Ohio*

Although it is widely recognized that participation in social activities can have a positive effect on both physical and mental well-being among older adults, this topic is under-addressed in studying the aging population in China. The purposes of this exploratory study are to identify the patterns of social activities of interest to Chinese older adults and to explore how the demographic and socioeconomic factors influence their social activity involvement. This study is a secondary data analysis of the pilot survey conducted by China Health and Retirement Longitudinal Studies (CHARLS), which has 2,685 individuals (1,570 households) participating. The three activities (among the ten) with the highest participation rate: (1) helping family, friends and neighbors, (2) interaction with friends, and (3) light recreation such as playing ma-jong and chess. These activities are analyzed as dichotomous outcomes in a series of logistic regressions. For each outcome (participation in the activity or not) the same predictors are used for building three logistic models, respectively. According to the research findings, social activity involvement declines as one ages, regardless of the type of activity. The significance of each predictor varies and the direction of its impact differs with the activity. For example, older women are more likely to help family, friends and neighbors, as well as to participate in light recreation, while they are less likely than older men to interact with friends. Older adults with lower socioeconomic status are more likely to interact with friends, as well as to participate in light recreation.

### SOCIAL SUPPORT NETWORK CHANGES AND THEIR EFFECTS ON MENTAL HEALTH AMONG KOREAN ELDERLY IMMIGRANTS

H. Oh, *Sociology, University of Florida, Gainesville, Florida*

By taking the longitudinal, life-course perspective into consideration, this study investigated the association of social support network changes due to immigration with the level of depressive symptoms among community-dwelling Korean elderly immigrants aged 60 years and older (N=203). Survey participants have currently received more supports (esp., from children) than they did before immigration. Along with consistent emotional support, Korean elderly immigrants have sought for more instrumental and practical supports, i.e., informational and financial supports from their family members than they did before immigration. Nested multiple regression analysis revealed that along with poor health and recent occurrences of stressful life events, elderly Koreans who used to have nonkin-oriented support history and have failed to maintain or gain support from nonkin members and family members, respectively, after immigration, turned out to have more depressive symptoms than their peers who have continued to receive support from their family members. Confirming the hypothesis that there exists the lasting effects of previous social support network on the mental health of Korean elderly immigrant samples, the findings signify the importance of the life course perspectives for better understanding how and to what extent the history of social relations come into play in determining the quality of life of the elderly in general as well as Asian elderly immigrants.

### THE EFFECTS OF HEALTH STATUS AND SOCIAL STRUCTURE ON AGE-RELATED CHANGES IN SOCIAL NETWORKS

C.S. Marcum, *Sociology, University of California - Irvine, Irvine, California*

Gerontologists have long been interested in the intersection between age-related changes in social networks and health. Prior research has found that older people tend to incorporate a larger proportion of family members in their social networks than younger people. Leading explanations for this finding emphasize older peoples' agency, or preferences, for more kin-focused interactions. A complimentary hypothesis, however, is that other age-related changes in behavior, ability, and social structure affect the social networks of older people. In this paper, I test the hypothesis that age and poor health status both increase the ratio of time spent with family members to time spent with other types of relations. Results indicate that the ratio increases with age, but that the increase is faster for older people who are sick, net of other factors. The findings suggest that, while increasing the amount of social contact with family members relative to others is normative in old age, declining health status cannot be ruled out as a cause of extreme decline in the breadth of social interactions for older people. Further tests also show that working and high income mediate the affects of age, but not health status, on social contact with non-kin. This likewise suggests that changes in social structure associated with aging are important factors to consider in explaining why networks change as people age. Research and policy implications are discussed.

### ELDERS' LEVEL OF SOCIAL PARTICIPATION AND QUALITY OF LIFE MEASURED BY OBJECTIVE AND SUBJECTIVE INDICATORS

S. Choi[1], K. Ju[2], *1. Social Welfare, Seoul National University, Seoul, Republic of Korea, 2. Hanshin University, Osan, Republic of Korea*

Previous studies on the relationship between the older persons' social participation and quality of life showed little attention had been paid to the quality of life by both objective and subjective measures. This study aims at exploring the relationship between the level of social participation and quality of life measured by objective indicators (objective QOL) and subjective indicators (subjective QOL). For this study, 586 elderly persons aged 60 and over residing in Metropolitan areas were interviewed with structured questionnaires. Social activities were categorized into fives areas: economic, social support, social gathering, religious, and self-development activities. The level of social participation was measured with whether or not participating in activities and the length of time for activities. The objective QOL was measured by an index of health status, level of living, housing conditions, family relations and social relations, whereas the subjective QOL was measured by a modified index of QOL originally developed by WHO. Social participation in itself in all five areas of social activities was positively related to the subjective QOL while participation in itself in only economic, social gathering, self-development activities were positively related to the objective QOL. Of the five areas of social activities in terms of the length of participation, only religious activities were positively related to subjective QOL while economic, religious and self-development activities were positively related to the objective QOL. In regard to these findings, theoretical and social policy implications will be discussed.

### SOCIAL RELATIONS AND PHYSICAL ACTIVITY AMONG OLDER ADULTS: A NEW MEASURE OF SOCIAL STRAIN

K. Cotter, *Psychology, Sacramento State University, Sacramento, California*

Social relationships influence health directly and indirectly via health behaviors including physical activity. Higher social support typically predicts more physical activity, but the relationship of social strain to physical activity remains controversial. To determine the influence of social strain on physical activity, I examined a newly created measure of social strain for exercise (SE) for its potential efficacy among older adults. As expected, based on cross-sectional data from 166 older adults (64% women), SE from the spouse/partner was significantly related to perceived spouse/partner strain (r = .61, p < .001), SE from family members was significantly related to perceived family strain (r = .53, p < .001), and SE from friends was significantly related to perceived friend strain (r = .41, p < .001). SE was also positively correlated with social support for exercise from the spouse/partner (r = .52, p < .001), family (r = .44, p < .001), and friends (r = .29, p = .003). However, neither SE from the spouse/partner (r = -.18, p = .26), nor family (r = -.10, p = .47), nor friends (r = -.10, p = .40) was significantly related to physical activity, potentially due to the limited variability of SE in this sample. While SE was not directly related to physical activity, results suggest a potential similarity between social support for exercise and social strain for exercise. Future investigations should examine whether interactions intended as positive (e.g., encouragement for exercise) are actually being interpreted by recipients as negative (e.g., nagging).

## SESSION 510 (SYMPOSIUM)

### SOCIAL SUPPORT, SOCIAL CONTROL, AND DISEASE MANAGEMENT IN LATER LIFE

Chair: *K. August, University of California, Irvine, Irvine, California*
Co-Chair: *M.P. Stephens, Kent State University, Kent, Ohio*
Discussant: *C.A. Berg, University of Utah, Salt Lake City, Utah*

Social network members, particularly spouses, often are involved in the disease management of their chronically ill partners. Spouses can promote health behaviors related to their partners' disease management by serving as sources of support and influence. Health-related social support refers to network members' efforts to encourage individuals to maintain health-enhancing behaviors. Health-related social control refers to network members' attempts to monitor and influence individuals' health behaviors. Although these two social network functions are conceptually and empirically distinct constructs, they often co-occur in close relationships. Rarely, though, have researchers examined both dynamics of relationships in the context of disease management. This symposium presents data from The 2-partner Diabetes Management (T2DM) study that addressed how social support and control influenced the disease management of 129 older adult couples in which one partner had type 2 diabetes. The study objectives, methodology, and sample characteristics will be discussed first (Stephens). Next, associations of spouses' support and control with patients' diet adherence and diabetes anxiety will be reported (Franks, Iida). Data then will be presented on how gender and spouses' dietary responsibilities influence patients' dietary management (Hemphill, Khan). The implications of patients' and spouses' discrepant commitment to disease management will be discussed next (Rook). Finally, the impact of engaging in support and control on spouses' health will be examined (August). The presentations highlight that disease management occurs in an interpersonal context, with implications for both patients and their spouses. The discussant (Berg) will identify major themes from the presentations and offer suggestions for future research.

### T2DM STUDY: PURPOSE, DESIGN AND CHARACTERISTICS OF COUPLES

M.P. Stephens, *Kent State University, Kent, Ohio*

Our study investigated associations of spousal support and control with patients' dietary adherence, as well as health outcomes for both patients and their spouses, and how these associations differed by gender. Data were collected using a 3-wave design with assessments at baseline (T1), six months (T2) and twelve months later (T3). At all waves, in-person interviews were conducted with each partner, and at T1 and T3, each partner completed end-of-day diaries for 24 days. Patients had to be at least 55 years of age, have a diagnosis of diabetes and be in a heterosexual marriage-like relationship with a non-diabetic partner. T1 sample comprised 129 couples. On average, patients and spouses were 66 years old, had 14 years of education, had an annual income of $35,000, and had been married for 38 years. Three-quarters of couples were Caucasian and the remainder was African American. Female patient dyads represented half the sample.

### SPOUSES' DAILY SUPPORT AND CONTROL AND PATIENTS' DAILY DIETARY ADHERENCE AND DIABETES ANXIETY

M. Franks[1], M. Iida[2], *1. Purdue University, West Lafayette, Indiana, 2. Kent State University, Kent, Ohio*

This dyadic study examined spouses' efforts to support and to control daily diet behaviors of their partners with diabetes, and associations with patients' daily dietary adherence and diabetes-related anxiety. On each of 24 days, spouses recorded their provision of diet-related support, persuasion, and pressure to their partner. Patients recorded their diet adherence and diabetes-related anxiety. Multilevel analyses revealed that on days when spouses provided greater diet-related support than usual, patients had increased diet adherence. On days when spouses provided more diet-related persuasion than usual, patients had (marginally) decreased diet adherence. On days when spouses provided more diet-related pressure than usual, patients had (marginally) decreased diet adherence and increased diabetes anxiety. Findings suggest the beneficial role of spouses' diet-related support for their partners' daily diet management, but also indicate that spouses' control attempts can have unwanted consequences for patients' daily diet adherence and their illness adjustment.

### DIET-RELATED INTERACTIONS AND DIETARY MANAGEMENT IN COUPLES COPING WITH DIABETES

R.C. Hemphill, C. Khan, *Department of Psychology, Kent State University, Kent, Ohio*

Little is known about each partner's role in diet-related interactions in couples in which one partner has diabetes. Moreover, patients' gender and the dietary behaviors of the nondiabetic partner could have implications for the influence of couples' diet-related interactions on patients' dietary management. This study of older adults with diabetes and their nondiabetic spouses investigated the influence of patients' gender and spouses' diet on the associations between couples' diet-related interactions and patients' dietary management. Female patients' diet was better when meal planning was primarily their responsibility, whereas, male patients' diet was better when meal planning was primarily their wives' responsibility. Additionally, wives' dietary choices were more influential to male patients' diet when wives were responsible for meal planning compared to when couples shared meal planning. Findings indicate that traditional gender roles in dietary interactions are beneficial to patients' dietary management.

### REACTIONS TO SPOUSAL CONTROL WHEN PATIENTS AND SPOUSES DIFFER IN THEIR COMMITMENT TO THE MANAGEMENT OF DIABETES

K.S. Rook, *University of California, Irvine, California*

Health-related social control is believed to arouse psychological distress when social network members, but not target persons, want the target person's health behavior to change. In the context of chronic illness, patients and their social network members are more likely to share a commitment to the patient's disease management, including health behavior change. Here, too, however, social network members and patients can differ in their degree of commitment to the disease management goal, which may affect patients' reactions to social control. We examined this idea in the current study by contrasting couples in which the diabetic patients and their spouses had similar versus discrepant disease management commitment. When the spouse's commitment exceeded that of the patient, spousal social control elicited significantly more negative emotional and behavioral reactions (ps < .01). The findings help to identify the specific conditions in which social network members' influence attempts may elicit negative reactions.

### HOW ARE SPOUSES AFFECTED BY ENGAGING IN HEALTH-RELATED SOCIAL SUPPORT AND CONTROL?

K. August, *University of California, Irvine, Irvine, California*

To date, research has focused on recipients of health-related social support and control; little is known about consequences for the support or control provider. Spouses may experience negative effects from having to spend considerable time and effort making sure their partners are adhering to their treatment regimen. We examined whether spouses' daily involvement in patients' food choices was associated with adverse psychological consequences. Spousal exertion of social control was significantly related to same-day increases in spousal stress and marital tension, whereas provision of support was significantly associated with same-day decreases in spousal stress and increases in marital enjoyment. Greater patient dietary adherence buffered the adverse effects of control, and magnified the positive effects of support, on marital interaction quality. Findings underscore that managing a chronic condition in the context of a marital relationship has implications for not only the patient, but also for the spouse.

## SESSION 515 (SYMPOSIUM)

### THE AGING SERVICES NETWORK AS A PUBLIC HEALTH INTERVENTION

Chair: *S. Albert, University of Pittsburgh, Pittsburgh, Pennsylvania*

The important Institute of Medicine report, Retooling for an Aging America (2008), focused on the health care workforce, defined as health care professionals, paraprofessional direct care workers, and unpaid family caregivers. The report neglected another workforce, the aging services network, a loose network of profit, nonprofit, and government organizations that deliver mandated services to disabled elders. These agencies provide meals, transportation, home modification, social visiting, daily monitoring, house cleaning, and medication management when families are unable to provide such care. This symposium will examine how we can best harness the aging services sector for public health intervention research. Presenters will cover cutting-edge efforts to harness the aging services network for public health interventions. Studies include: (i) Use of the aging services network to promote uptake of clinical preventive services using the Sickness Prevention Achieved through Regional Collaboration (SPARC) model (Benson); (ii) Large-scale roll-out of an arthritis exercise program (Fit and Strong!) in area agencies of aging (Hughes); (iii) Use of home health paraprofessionals to deliver the Fit & Strong! program in elders' homes (Prohaska); and (iv) Assessment of the capacity of aging services agencies to screen for depressive symptoms and deliver preventive services (Albert). Discussants from CDC (Anderson) and AoA (Tilly) will provide comment.

### SPARC (SICKNESS PREVENTION ACHIEVED THROUGH REGIONAL COLLABORATION) AS A MODEL FOR ENGAGEMENT OF AGING SERVICES IN PUBLIC HEALTH

W.F. Benson, *CDC, Atlanta, Georgia*

CDC's Healthy Aging Program (HAP) has long viewed the "Aging Services Network" (ASN) as a critical partner in prevention related to chronic disease and other health conditions associated with aging. This presentation will emphasize efforts undertaken by CDC with the ASN to promote increased access to and use of recommended clinical preventive services (CPS — e.g., immunizations, cancer screenings) among older adults, particularly the delivery of multiple CPS in community settings. CDC's work with SPARC (Sickness Prevention Achieved through Regional Collaboration) will be highlighted. SPARC has shown great promise in increasing use of CPS to older adults including through an area agency on aging covering a large diverse community. SPARC's pioneering Vote & Vax initiative will be discussed. Also emphasized will be collaborative efforts between CDC and the Administration on Aging (AoA) to increase the use of CPS by older adults, including making essential data more accessible by the ASN.

### DISSEMINATING FIT AND STRONG WITH AREA AGENCIES ON AGING: LESSONS LEARNED

S.L. Hughes, *Center for Research on Health and Aging, University of Illinois Chicago, Chicago, Illinois*

Little is known about the successful translation and diffusion of evidence-based programs for older adults. Arthritis is currently the most common chronic condition affecting older adults and the number one cause of disability among them. This presentation will describe collaborative efforts currently underway to translate and diffuse Fit and Strong!.- an evidence-based physical activity/ behavior change program for older adults with lower extremity (LE) osteoarthritis. Fit and Strong! is an 8-week program that was tested in two prior efficacy and effectiveness randomized trials. Results showed that participants experienced significant improvements in exercise adherence, LE stiffness, pain, and function, and depression/ anxiety as well as LE strength and aerobic capacity at 18 months. Fit and Strong! is currently being diffused in Illinois and North Carolina through partnerships with local Area Agencies on Aging with funding from the Centers for Disease Control and Prevention (R18DP001140). Glasgow's RE-AIM framework is being used to guide dissemination efforts. To date, 32 providers have adopted the program, enrolling over 430 new participants. A total of 101 instructors have successfully completed Fit and Strong! instructor training. We have used qualitative methods to examine barriers and facilitators to adoption and maintenance, site visits to monitor fidelity, and pre-post participant outcomes to monitor continued program effectiveness. Findings from all of these efforts will be presented. Successful strategies for overcoming barriers to program implementation and maintenance will be described along with revisions to Instructor training to boost program fidelity.

### USING HOME CARE AIDES IN TRANSLATING STRONG FOR LIFE INTO THE COMMUNITY CARE PROGRAM

T. Prohaska, *Center for Research on Health and Aging, University of Illinois Chicago, Chicago, Illinois*

Given the high prevalence of sedentary behavior among older adults and the potential benefits of PA in secondary and tertiary prevention, it is critical that successful PA programs reach those who typically do not participate in group-based exercise programs, especially frail home bound adults. Illinois provides home and community based services to over 50,000 frail older adults annually through their Community Care Program (CCP). Home Care Aides (HCA) provides personal care services to CCP clients in their home. The presentation present findings on the feasibility of implementing Strong for Life, an evidence-based exercise program designed for frail older adults, by training home care workers to administer the program in the care recipient's home. Using a two group 4-month pre-test post-test design, HCA trained in delivering SFL are compared to a treatment delay control group. Measures include levels of reported PA and functional status.

### ASSESSING CAPACITY OF NONPROFIT SENIOR SERVICES AGENCIES TO IMPLEMENT DEPRESSION SCREENING, TREATMENT, AND REFERRAL

S. Albert, *University of Pittsburgh, Pittsburgh, Pennsylvania*

The aging services network provides meals, transportation, home maintenance, and other supports for seniors at risk for nursing home placement. Owing to such contact, these agencies are well placed to screen seniors for depressive symptoms and prevent onset of depression. We assessed the capacity of aging services providers in Pittsburgh, PA to provide depression screening and referral. Of 70 agencies randomly sampled, 42 participated in a web-based survey. The survey showed that less than 20% screen for depression with structured assessments. Only a third have regular referral sites for depression care. Among agencies that make referrals, only half consider the referral sites effective in providing treatment. Agencies that used formal screening tools were more likely to follow-up on referrals and to consider referral partners effective. Thus, we have introduced a depression prevention model that trains front-line home care providers to screen using formal assessment tools. A randomized controlled trial will follow.

### DISCUSSION: AGING SERVICES AND PUBLIC HEALTH INTERVENTIONS: THE VIEW FROM CDC

L. Anderson, *CDC, Atlanta, Georgia*

Discussion by Lynda Anderson, PhD, Director, Healthy Aging Program, Division of Adult and Community Health, NCCDPHP, CDC

### DISCUSSION: AGING SERVICES AND PUBLIC HEALTH INTERVENTIONS: THE VIEW FROM THE ADMINISTRATION ON AGING

J. Tilly, *Administration on Aging, Washington, DC, District of Columbia*

Jane Tilly, PhD, Project Officer, Administration on Aging, will discuss efforts at AoA to mobilize aging services for public health prevention efforts

### COGNITIVE HEALTH: AN OVERVIEW OF COGNITIVE INTERVENTION RESEARCH

S. Pasupuleti, *Social Work, The University of Toledo, Toledo, Ohio*

Intervention research linking cognitive functioning with physical, mental, and social activities has huge implications for policy and programs shaping the lifestyle of older adults. On the whole, the notion of enriched and stimulating environment is imperative for healthy cognitive aging because neurons in the brains of individuals exposed to intervention stimulation and enriched environments showed improved neural health (Greenough, McDonald, Parnisari, & Camel, 1986). This promising research evidence needs to be translated into interventions and promote public health. The National Institutes on Aging, Health and Mental Health, and Center for Communicable Diseases have recognized the need for a public health movement focusing on the cognitive health of the aging population and have crafted the "Cognitive and Emotional Health Project" (CEHP) to begin to address issues related to this area of concern. More interventions are needed at community level for promotion of healthy aging and prevention of cognitive impairment and dementias.

## SESSION 520 (SYMPOSIUM)

### BSS PRESIDENTIAL SYMPOSIUM: THE GREAT TRANSITION: HOW MORTALITY ORGANIZES BEHAVIOR IN LATER LIFE

Chair: *D. Ekerdt, University of Kansas, Lawrence, Kansas*
Discussant: *S. McFadden, University of Wisconsin, Oshkosh, Wisconsin*

All around, no transition is more consequential than death. The temporal logic of behavioral and social science favors the study of antecedents and consequences—things happen and people react or cope. Yet expectations for the future are also a powerful motivation for behavior. If people foresee a likely occurrence, they may adapt to it in advance or incline their actions in some way. This symposium will explore how people live and behave in light of the finitude of life time. We will step back from immediate issues about patient care and decisions at the end of life to consider how human mortality shapes people's outlooks, affairs, and daily life for years, even decades, in advance. Modernization has brought a progressive removal of death from childhood and middle age; in later life, medicine offers a promise to fight and postpone it. Yet, even if the hour of death is uncertain, people remain strongly aware of its eventuality, and progressively so as life proceeds. The distinguished presenters at this symposium will explain elders' growing awareness that life's time is short; how that awareness shapes practical affairs, relationships, and the imagination of the future; and how reminders of death are a persistent feature of culture. Even in an era that is said to deny death, mortality very much dwells among the living.

### TAKING TIME SERIOUSLY IN LIFE-SPAN DEVELOPMENT

L. Carstensen, *Stanford University, Stanford, California*

To the best of our knowledge, humans are unique in their ability to anticipate their mortality early in life. Gradually chronological age comes to serve as a marker of time left in life. Socioemotional selectivity theory – a life-span theory of motivation- maintains that this shift in perceived time has profound and systematic implications for the types of goals people pursue, the decisions they make, and even what they see, hear and remember. In this talk, I will argue that a deep understanding of human development must take time very seriously.

### ANTICIPATING WIDOWHOOD: WHO AVOIDS, WHO PREPARES, AND WHY?

D. Carr, *Rutgers University, New Brunswick, New Jersey*

The vast majority of older adults will die of chronic illness; thus, for most older adults – especially women - the death of a spouse is an anticipated transition. Despite this demographic reality, older adults often report shock and severe grief symptoms upon spousal deaths they deem "unexpected," and couples often fail to discuss how the surviving spouse will manage financially after the loss. Thus, I explore two questions. First, what factors affect an older adult's perceived likelihood of their spouse's death; this analysis uses data from the Wisconsin Longitudinal Study, a long-term study of men and women who graduated Wisconsin high schools in 1957. Second, I use data from the Changing Lives of Older Couples study to explore whether expected versus unexpected spousal deaths trigger psychological distress and perceived financial strain among older recently bereaved widow(er)s. I discuss implications for policy and practice, particularly for formal end of life planning.

### HUMANS ARE MORTAL?! I'M CALLING MY ATTORNEY

M. Kapp, *College of Medicine, Florida State University, Tallahassee, Florida*

Humans reluctantly acknowledge that we are mortal, and that "You can't take it with you." Nonetheless, many people still desire and attempt to exercise some degree of control—even postmortem—over their individual legacies. A variety of legal tools exist for helping individuals accomplish such postmortem control, or at least influence, over their legacies, and awareness of the potential legal consequences of failure to adequately plan for the certain eventuality of death (for example, excessive estate taxes or family disputes over inheritances) acts for many as a powerful incentive to take advantage of available planning opportunities. This presentation will survey the legal incentives and opportunities people have to plan regarding their legacies, as well as impediments that interfere with the timely use of legal planning options by many people. Research questions examining how people respond to legal incentives surrounding anticipation of death will be suggested.

### WHEN DEATH WAS EVERYWHERE: NINETEENTH-CENTURY RESPONSES TO THE THREAT OF MORTALITY

C. Haber, *School of LIberal Arts, Tulane University, New Orleans, Louisiana*

Over the course of the last century, expectations of when and how an individual should die have undergone a dramatic transformation. With the elimination of childhood diseases and public health threats, we now assume that dying is largely the concern of the old. Although this belief is so pervasive it seems almost timeless, in truth, it is a very modern phenomenon. Before the recent century, death could come at any age; individuals had to be constantly aware that at any point, they could face the end of their days. This perception had an important impact on the way people approached their daily lives, constructed their families and even prepared themselves for dying. By examining beliefs about mortality in nineteenth-century America, this paper will discuss how the ever-constant presence of death not only organized behavior in later life but cast a long shadow over every stage of existence.

## SESSION 525 (SYMPOSIUM)

### THE SCHMIEDING CAREGIVER TRAINING PROJECT: REPLICATION OF A PROVEN PROGRAM

Chair: *R.E. McAtee, Donald W. Reynolds Institute on Aging, University of Arkansas for Medical Sciences, Little Rock, Arkansas*

The Donald W. Reynolds Foundation awarded the Arkansas Aging Initiative, Donald W. Reynolds Institution on Aging at the University of Arkansas for Medical Sciences, a grant to replicate the Schmieding Home Caregiver Training program in four Arkansas rural sites. The Schmieding program is designed to train persons who want to become geriatric home caregivers and/or family members who want more skills to care for an older adult in the home. It is built around four levels of progressive classroom training and has a ten year history of success. This program uses the infrastructure of the Arkansas Aging Initiative's (AAI) network of eight regional Centers on Aging to implement the training. The AAI's mission is to improve health outcomes of older Arkansans through interdisciplinary clinical care and innovative education programs. Therefore, these centers provide a wonderful educational base of support for implementing this training in the regional communities. A nine-month planning grant was awarded to the AAI in 2008 to carefully examine what was needed and how the actual training programs could be established statewide. During this time, a strategic plan was developed which included the development of goals, objectives and strategies to accomplish the overall mission. The four main goals revolve around the administrative and operational structure, implementation details, process and outcome evaluation, and sustainability plans. We now have two sites that have started classes and two more to start in the spring of 2011. The outcomes of the first two sites are very exciting and will be reviewed.

### THE ARKANSAS AGING INITIATIVE: AN INFRASTRUCTURE FOR SUCCESSFUL REPLICATION

C.J. Beverly, R.E. McAtee, *College of Nursing, University of Arkansas for Medical Sciences, Little Rock, Arkansas*

The Arkansas Aging Initiative (AAI) is a rural network of eight Centers on Aging whose mission is to improve the quality of lives and quality of care for older adults through two primary components, education and clinical care. The education program is funded through a portion of Arkansas' share of the Master Tobacco Settlement and the clinical program is fully supported by partner hospitals in the local/regional area. A primary mission of the education program is to increase geriatric expertise of health care professionals, para-professionals, students, and older adults and their families and the community. The education and clinical components are co-located resulting in increased synergy and visibility to the community. Thus, the AAI infrastructure is poised to quickly move strategic programming throughout the state thereby increasing access to the more rural part of the state.

### THE REPLICATION GRANTS FROM THE DONALD W. REYNOLDS FOUNDATION

R.E. McAtee, L.D. Wright, C.J. Beverly, S.L. White, *University of Arkansas for Medical Sciences, Little Rock, Arkansas*

The AAI first received a planning grant from the Reynolds Foundation in 2009 to examine the feasibility and the readiness of the AAI network to start such a large endeavor. During this phase, a strategic plan was developed that included four basic objectives: development of the potential administrative structure, development of an implementation plan, examination of sustainability options, and the development of a comprehensive evaluation plan. While writing the implementation plan, a site readiness evaluation was completed for all eight centers on aging, a comprehensive budget was created and the decision was made to have an active state advisory committee as well as local advisory committees when the sites begin operations. After fifteen months of operation, two sites are up and operating with two more sites in the start-up phase. Challenges and outcomes of the planning and implementation phases will be reviewed.

### OUTCOMES OF THE SCHMIEDING HOME CAREGIVER TRAINING REPLICATION PROJECT

S.L. White, *Donald W. Reynolds Institute on Aging, University of Arkansas for Medical Sciences, Rogers, Arkansas*

Over the course of the startup period for this grant much has been accomplished and many lessons have been learned. Grant personnel conducted ongoing process evaluation at the state and local levels which was used to improve the process for other sites. This section presents an overview and summary of the outcomes data resulting from the start up of the first two sites, explains how the information was collected and discusses how the information is being used to improve the start up and implementation of future sites. Specific information will include the method of evaluation, selected tools, and specific qualitative and quantitative outcomes data collected. A discussion of the successes, challenges and outcomes of the planning and implementation phases will also be addressed.

## SESSION 530 (SYMPOSIUM)

### VA GRECC SYMPOSIUM: DELIRIUM AND DEMENTIA IN OLDER PATIENTS FOLLOWING CRITICAL ILLNESS

Chair: *E.W. Ely, GRECC, VA Tennessee Valley Healthcare System, Nashville, Tennessee, Vanderbilt University, Nashville, Tennessee*

This symposium will present state-of-the-art reviews of the latest data on delirium and the increasingly recognized persistent cognitive impairment being reported following hospitalization for acute medical and surgical illnesses. Delirium is a classic geriatric syndrome serving as the strongest determinant of hospitalized patients' length of stay and disposition. It carries enormous financial and societal burdens due to its association with increased morbidity, mortality, prolonged hospital stay, and cost of care. Due to the increased aging of our population—who have multiple medical problems, pre-existing cognitive impairment and increased risk of functional decline—the toll of delirium is growing exponentially. This toll is not merely measured in lives lost, but also in reduced quality of life, frailty, depression, posttraumatic stress disorder, and most importantly the persistent cognitive dysfunction akin to dementia. The talks will include (a) the epidemiology and public health impact of delirium and long-term cognitive impairment, (b) clinical interactions between delirium and psychiatric comorbidities including PTSD and depression, (c) pharmacological and non-pharmacological management of delirium following acute illness, and (d) new data exploring the role of cognitive rehabilitation following delirium and critical illness to regain executive function.

### FACING THE CHALLENGE OF DELIRIUM AMONG OLDER HOSPITALIZED MEDICAL PATIENTS

J.H. Flaherty, *1. Internal Medicine/Geriatrics, St. Louis VA GRECC, St. Louis, Missouri, 2. Saint Louis University, St. Louis, Missouri*

This section of the symposium specifically focuses on older hospitalized medical patients who are admitted with delirium or develop delirium during admission. After this section, participants will (1) understand, based on the complex pathophysiology of delirium, why this syndrome is so difficult to manage; this understanding is key to the next two objectives; (2) understand, based on the pathophysiology and all the available data on use of antipsychotics and delirium why antipsychotics have limited use in the prevention and treatment of delirium; (3) have knowledge of the non-pharmacological preventive and management interventions that have been shown to be effective.

### PATHOPHYSIOLOGY OF DELIRIUM: POSSIBLE MECHANISMS OF BRAIN DAMAGE IN CRITICAL CARE SETTINGS AND IMPLICATIONS FOR INTERVENTION

B. Kamholz, *Durham VA, Duke University, Durham, North Carolina*

This session will update our knowledge regarding the pathology of cellular and molecular mechanisms in delirium. While there are many hypotheses regarding these causes, including theories of neuronal aging, disorders of neurotransmitter metabolism, inflammation, and the HPA axis as well as oxidative stress, it appears that the most basic mechanisms of cellular function may represent the "final common pathophysiological pathway." A review of oxidative metabolism and the impact of its disorders on neurotransmitter function and availability in delirium will be provided. In addition, inferences about the impact of systemic inflammation on cognition and behavior in delirium will be addressed. The implications for potential pharmacological treatments will be reviewed.

# SESSION 535 (POSTER)

## WORK AND RETIREMENT

### EXPECTATIONS OF FORCED RETURN TO WORK FOLLOWING RETIREMENT: A CROSS-CULTURAL COMPARISON

C.M. Darling[1], D.A. Hershey[1], K. Henkens[2,3], H. van Dalen[2,3], *1. Psychology, Oklahoma State University, Stillwater, Oklahoma, 2. Netherlands Interdisciplinary Demographic Institute, The Hague, South Holland, Netherlands, 3. Tilburg University, Tilburg, Netherlands*

Many individuals find they have to return to work for economic reasons after having retired. Although articles on this topic routinely appear in the popular press, scientific studies on this return-to-work phenomenon have lagged behind. In the present investigation, we examined workers' expectations of whether they would need to re-enter the workforce after having been retired. Data were analyzed from Dutch (N=787) and American (N=603) working adults, 25-64 years of age. In addition to measuring perceptions of the need to return to work for economic reasons, all participants completed a questionnaire that assessed psychological, social, and economic determinants of financial preparedness for retirement. Across the entire sample, one in six workers believed that they would need to return to work based on financial concerns; however, analyses failed to reveal a cross-national difference along this dimension. Separate country-specific regression analyses were also carried out that were designed to predict expectations of returning to work using the three qualitatively different sets of (psychological, social, and economic) predictors. In these analyses, striking cross-national differences were observed, with roughly twice as much explained variance seen in the American models relative to the Dutch models. Cross-national differences were also observed among the specific indicators that were predictive of the criterion: advanced age was a powerful predictor for the Dutch, whereas failing health and inadequate savings were strong predictors for Americans. Findings are discussed in terms of the importance of identifying characteristics of individuals who might benefit from pre-retirement interventions.

### BURDEN OF EMPLOYED CAREGIVERS

A.D. Boer[1], S. Keuzenkamp[1], M. Broese Van Groenou[2], *1. Care, The Netherlands Institute for Social Research, The Hague, Netherlands, 2. VU University Amsterdam, Amsterdam, Netherlands*

Paid employment and informal care can get in each other's way because both can make claim on the available time and because combining tasks can be burdensome. This study discusses whether the burden of giving care and working characteristics and strategies of combining work and informal care related. Bivariate analyses has shown that informal carers with a full time job and those who apply care and work strategies experience a higher burden than people who work part-time and non-appliers. However, when other factors were taken into account, such as intensity of care and characteristics of informal carers, the relationship between flexible working hours and burden was no longer significant. Taking time off and reduced working hours remained positively related to burden. In general, working characteristics and strategies only partly explain variance on the burden. The most important factors proves to be the social relation between informal carer and receiver and the intensity and the complexity of the care situation.

### WHO WORKS AMONG OLDER BLACK AND WHITE, WELL-FUNCTIONING ADULTS IN THE HEALTH ABC STUDY?

R.N. Rooks[1], T.B. Harris[2], *1. Health and Behavioral Sciences, University of Colorado Denver, Denver, Colorado, 2. National Institute on Aging, Bethesda, Maryland*

Productive aging relates to employment through active social and physical functioning, but it may have a bi-model pattern, where elderly work to stay healthy or for economic necessity. Political economy of aging suggests that unequal power in society causes unequally-distributed resources through educational, labor force, and health care systems, resulting in racial groups experiencing aging differently. We examine if working vs. not is associated with greater financial and/or social needs and Black vs. White adults being more likely to work. Logistic and multinomial logistic regression (MLR) analyses were used to model working or not and full-time, part-time, and non-workers by sex in the Health, Aging, and Body Composition study, a 14-year cohort study with 3,075 community-dwelling, well-functioning Black (42%) and White, women and men, aged 70-79 in Memphis, TN and Pittsburgh, PA. Among men, Black vs. White adults, those in Memphis vs. Pittsburgh, those with ≥\$50,000 vs. <\$10,000 family income, and those who drank ≥1-7 times per week had a significantly greater odds of working vs. not. Among women, Black vs. White adults and being overweight vs. normal BMI had a significantly greater odds of working vs. not; however, those with diabetes had significantly lower odds of working vs. not. MLR analyses showed similar significant trends existed for men for full-time vs. non-workers only and for women, in part-time vs. non-workers only, except that having ≥\$50,000 vs. <\$10,000 income was significantly associated with full-time vs. non-workers. Future research could examine cultural and community differences in site, possibly impacting work status.

### WORKING RETIREMENT: LESSONS ABOUT AGING, PRODUCTIVITY, PURPOSE, AND SOCIAL ENGAGEMENT FROM A SUBURBAN BOSTON FACTORY

C. Lynch, *Olin College of Engineering, Needham, Massachusetts*

This poster engages questions about work, aging, gender, community, value, and business profitability by examining the motivations and experiences of workers and employers at Vita Needle Company, a family-owned factory that produces stainless steel needles in a suburban Boston factory. The average age of the 40 employees is 75, and the eldest is a 98-year-old former waitress who joined the factory when she was 85. As U.S. senior citizens face dwindling retirement savings and rising costs of living, many seek work that simultaneously satisfies their social and economic needs. This poster is based on a book project called _Working Retirement: Age and Value in a Suburban Factory_. The book (in process) is an ethnographic study that comes at a critical time—when social and economic changes in the United States and Europe challenge us to examine our cultural assumptions about the value of work, the experiences of retirement, and what constitutes "successful aging." The poster will include vivid photos from inside Vita, and will focus on particular Vita employees and specific workplace and family interactions that illuminate understandings of work, community, value, and belonging. The poster also situates Vita in the context of global concerns about the "graying of society" and ethical and policy debates about the value of work for older adults. The poster is based on four years of anthropological fieldwork, interviews, and literature review, including an intensive period of participant observation in summer 2008 when the researcher worked on the Vita production floor making, inspecting, packing, and shipping needles.

### SPORTS ACTIVITIES IN RETIREMENT: A COMPARISON ACROSS COHORTS

R. Cozijnsen, N. Stevens, T. Van Tilburg, *VU University Amsterdam, Amsterdam, Netherlands*

An active life style after retirement is beneficial for health and well-being in later life. Involvement in formal and informal social participation after retirement has been studied extensively. Participating in sports activities, however, has received much less attention. The aim of the current study is to investigate trends in participation in sports activities of successive birth cohorts of early retirees in The Netherlands. Opportunities for exercise change after retirement and incentives change as well. Moreover, the importance attached to sports activities has increased in recent decades. Data are from seven observations (between 1983 and 2007) of a nationally representative Dutch survey. At each observation a sample of early retirees (aged 56-64) was drawn. For cross-sectional comparison older workers (aged 56-64) were included in the analysis. The total number of respondents was 2475 (early retirees, N=799, older workers, N=1676). Results demonstrate increases in participation in sports activities among successive birth cohorts of early retirees. Logistic regression analysis showed that increased sport club membership and participation in organized sport activities was related to cohort changes in level of education, working class and health. No differences were demonstrated between those who retired early and those who continued working. The observed trend in sports activities among successive Dutch cohorts of retirees suggest that policies promoting a healthy post-retirement lifestyle should aim at increasing participation in sports activities earlier in the life course.

### PREDICT SAVING BEHAVIOR FOR RETIREMENT: APPLICABILITY OF THE THEORY OF REASONED ACTION

C. Liou, I. Leech, *Virginia Tech, Blacksburg, Virginia*

Social Security will not provide an income in retirement on which many people will be content to live (Cook & Johnson, 2000). Therefore, it becomes essential to promote saving for retirement. The researchers are curious about how people save for their retirement during this tough economic downturn. According to the theory of reasoned action, a decision to engage in a behavior is directly predicated by an individual's intention to perform the behavior (Fishbein & Ajzen, 1975). Individuals' assessment of salient outcomes for retirement saving can be measured and combined into a testable casual model that links beliefs to intention to save and the behavior to save. In this study, we examined the utility of the theory of reasoned action for predicting saving for retirement. A structural equation model was used. In addition to outcome beliefs, normative beliefs, attitude, subject norm, and intention to save for retirement, the model also included some demographic variables to enhance the theoretical model. The data came from a southern Virginia population with participants' age ranging from 25 to 70. Almost half of sample reported having no dependent child now but having three different loans (e.g., credit card loan, auto loan and mortgage). Although 86 % of participants have no specific retirement plan, more than half of them would like to learn more about retirement. The implications of these findings will provide researchers, policy makers, and financial planners with a picture of current attitudes on saving for retirement.

### RETIREMENT AS AN OPENING GATE: EXPECTATIONS AND IDENTITY IN THE THIRD AGE

M. Dickhans, M. Takahashi, *Northeastern Illinois University, Chicago, Illinois*

For many retirees in our society, continued vitality into the seventh and eighth decades of life is ushering in a "third age," a period of time with potential for prolonged developmental activity and productive engagement that may last 20 to 30 years. This study examined the transition to retirement in terms of "mode of adaptation" (one's views and expectations of retirement), and "identity style," (level of identity balance; or one's predominant approach to maintaining identity in the face of retirement and aging changes). 38 female (mean age=71.32) and 20 male (mean age=70.75) retirees, who had been retired, on average, 8.33 years (SD=5.95), were recruited from several retirement communities in a metropolitan city in the Midwest. The participants completed seven instruments on retirement expectations, identity balance, financial and lifestyle retirement planning, quality of life, and socioeconomic status. The overall results revealed that people in the "new beginning" mode of adaptation had a high level of identity balance. Results also showed that mode of adaptation and identity balance were associated with quality of life. A major implication of the study is that an individual's expectations of retirement and manner of coping with changes in later life may be essential factors in his or her adjustment to the retirement transition.

### PRE-RETIREMENT INDIVIDUALS' EXPECTATIONS FOR POST-RETIREMENT LIFE

E.A. Fenster, *Miami University, Oxford, Ohio*

Research has concentrated on the transition into retirement and post-retirement living situations, but has largely ignored the pre-retirement phase itself. Previous work has examined satisfaction with retirement after making the retirement transition, but this study extends that literature by examining a measure of anticipated (or expected) satisfaction among those who have not yet retired. The goal of this study is to examine how someone's perception of their living standard after retirement and their demographic characteristics are related to whether or not they are looking forward to retirement. Respondents (n = 8,579) come from the 1992 wave of the Heath and Retirement Study (HRS). Due to the lack of studies that focus on the pre-retirement phase, analysis includes variables identified by previous work as important to other phases of retirement and then examines their relationship with pre-retirement based on the life-course perspective (i.e., education, age, income, assets, gender, race, health status, and marital status). Multinomial logistic regression is used to examine the impact of demographic characteristics, as well as the mediating relationship of expected post-retirement living standard, on how one anticipates retirement. Results indicate that expectations for a higher post-retirement living standard are related to a more positive retirement anticipation. Clear differences in regards to gender and marital status are evident. However, racial differences provided a more mixed perception of anticipation, a finding not present in previous research. These varying attitudes about retirement expectations highlight the impact of past experiences and feelings related to agency and social structure.

### FALLING BEHIND IN YOUR RETIREMENT SAVINGS? FINDINGS FROM A CROSS-CULTURAL COMPARATIVE INVESTIGATION

D.A. Hershey[1], J.M. Jacobs-Lawson[2], K. Henkens[3,4], H. van Dalen[3,4], *1. Psychology, Oklahoma State University, Stillwater, Oklahoma, 2. University of Kentucky, Lexington, Kentucky, 3. Netherlands Interdisciplinary Demographic Institute, The Hague, South Holland, Netherlands, 4. Tilburg University, Tilburg, North Brabant, Netherlands*

Making regular long-term financial investments over the course of one's working life is a key to establishing a successful individual retirement savings program. Unfortunately, many people procrastinate when it comes to putting a saving plan in place, which can lead them to feel "behind schedule" in meeting their financial goals. Delaying the onset of a program of retirement savings not only results in the accumulation of fewer financial resources, but it can also lead to the onset of psychological distress—such as retirement anxiety (Hayslip et al., 1997) and retirement-oriented financial worry (Neukam & Hershey, 2002). The present study examined cross-cultural differences in individuals' perceptions of whether they were behind schedule when it comes to saving for retirement. Respondents were 632 Americans and 1040 Dutch pre-retirees, all between the ages of 25-64. The independent variables in this investigation included nationality (2 levels: Dutch/American) and age group (8 levels in 5-year increments: 25-29, 30-34…60-64). Analyses revealed that on average, across all age groups American pre-retirees felt significantly further behind schedule than the Dutch. This was true despite the fact that both groups intended to retire at approximately the same age, and Americans reported starting thinking about retirement planning some 8.3 years earlier than their Dutch counterparts. Additional analyses also identified cross-cultural differences in the indicators that were predictive of feeling behind schedule. The discussion focuses on how these cross-national findings could have emerged due to stable cultural differences in the channels of retirement support found in the two countries.

### INTERDISCIPLINARY INFLUENCES ON PERSONAL FINANCIAL PLANNING IN BRAZIL

L.H. Franca[1], D.A. Hershey[2], *1. Graduate Studies in Psychology, UNIVERSO - Salgado de Oliveira University, Niterói, Rio de Janeiro, Brazil, 2. Oklahoma State University, Stillwater, Oklahoma*

Brazil will face significant economic challenges in the coming decades when attempting to provide adequate public pension benefits for its retirees. One factor that could potentially mitigate this anticipated financing challenge will be the extent to which individual workers engage in retirement planning and saving activities. Little is known, however, about the mechanisms that underlie personal financial planning practices in this economically emerging nation. In the present study, we test an established interdisciplinary model of financial planning (Hershey, Henkens & van Dalen, 2010), in which psychological, social and economic indicators are posited to motivate engagement in the planning process. The conceptual model, which was evaluated based on responses from 167 Brazilian working adults (21-69 years of age), posited that psychological and economic forces would have a proximal influence on planning activities and savings. Social forces were anticipated to have a distal influence on planning and saving, with their effect hypothesized to be mediated through the psychological indicators. Path analyses revealed substantial support for the role of all three sets of forces in the planning process, as well as support for the model's overall conceptual structure. However, relative to comparable empirical models developed using Dutch and American workers, the Brazilian model revealed unique pathways involving social force indicators, such as the impact of early learning experiences on the development of financial knowledge, and the positive influence of friends and colleagues on savings adequacy. Findings are discussed in terms of cultural constraints on the development of interdisciplinary models of financial planning.

### WORK QUALITY OF LIFE AND INTENDED RETIREMENT AGE

F. Alpass, C. Stephens, A. Towers, J. Noone, *Psychology, Massey University, Palmerston North, New Zealand*

Early exit from the workforce provides policy challenges as the population ages. The main determinants of early retirement are health and wealth. A further factor, quality of work life, which may indirectly influence health status and wealth accumulation, has also been linked to early exit from the workforce. To investigate the relationship of these determinants to intended retirement age in a representative New Zealand sample, data from the Health, Work and Retirement study were obtained from 1574 full-time workers aged between 55 and 60 years of age. Data on intended retirement age, wealth (current income and anticipated finances), measures of well-being (self-rated physical and mental health, total number of illnesses), and quality of work life (work involvement, work social support, career commitment, career satisfaction, job satisfaction, leisure orientation) were obtained from postal questionnaires. As anticipated, those with higher incomes and higher anticipated retirement wealth intended retiring earlier. Those in poorer health and those who had a poorer quality of work life were also more likely to anticipate an early retirement. When controlling for wealth and health, work quality of life contributed significantly to the explained variance in retirement intentions. These findings support previous work linking poor work life quality with intentions to retire early. Quality of work life for older adults, as a factor in the retirement decision making process, is amenable to intervention. Investment in improving quality of work life will motivate older workers to stay in the workforce longer.

## SESSION 540 (SYMPOSIUM)

### AGING AND THE INTERPLAY AMONG ENERGY, MASS AND MOBILITY: FINDINGS FROM THE BLSA

Chair: *L. Ferrucci, National Institute on Aging, Baltimore, Maryland*
Discussant: *T. Manini, University of Florida, Gainesville, Florida*

Age-related changes in energy production and utilization and body composition have profound effects on mobility and autonomy. Improved understanding of these changes has become a central aim of the Baltimore Longitudinal Study of Aging (BLSA), established in 1958 as a continuous enrollment cohort of individuals as young as 20 to the end of life. Examinations occur every 1-4 years depending on participant age and last 2-3 days. The organizing paradigm consists of a hierarchical network of interdependent homeostatic processes and physiological domains that together impact mobility and speed of movement, hallmarks of aging. In this symposium we begin to address our central hypothesis that a progressively larger discrepancy between energy demand and energy availability produce the aging phenotype. We present secular trends in body composition change with age over the past 50 years and introduce an improved prediction model for resting metabolic rate that incorporates quantitative assessments of lean and fat mass to account for increased fatty infiltration of muscle mass with age. Next, we explore the energetic cost of performing a standardized walking task, a measure of energetic efficiency and how it changes from mid- to late-life. Lastly, we examine two potential threats to optimal energetic efficiency. The first focuses on knee osteoarthritis, a common condition of aging, and gait parameters relevant to biomechanical efficiency. The second evaluates thyroid function, a regulator of metabolic rate, and walking performance and energy use. Findings provide supportive evidence for our hypothesis, but also raise intriguing questions for further study.

### SECULAR TRENDS IN BODY WEIGHT: EVIDENCE OF AN EPIDEMIC OF INCREASING FATNESS FROM THE BLSA

S. Stenholm[2], E.M. Simonsick[1], L. Ferrucci[1], *1. National Institute on Aging, Baltimore, Maryland, 2. National Institute for Health and Welfare, Turku, Finland*

Estimates of increasing obesity in the US may simply reflect changing socio-economic and ethnic composition. This study examines secular trends in body weight in old age in three birth cohorts consisting of 1,364 well-educated Caucasian men born between 1877 and 1941 from the BLSA followed until death. Body weight was measured biannually with the last visit occurring between 1959 and 2008. Men born between 1920 and 1941 had higher body weight over the entire follow-up time compared with men born between 1900 and 1919 ($p < .001$) and 1877 and 1899 ($p = .001$); the difference was also significant between the two earlier birth cohorts ($p < .001$) all independent of height. An increasing trend in body weight across birth cohorts was also observed in the few years prior to death. Results confirm the obesity epidemic extends into late life in current elderly and is not a function of socio-demographics.

### ANTHROPOMETRIC PREDICTORS OF RESTING METABOLIC RATE (RMR) IN HEALTHY OLDER PERSONS

L. Ferrucci[1], J. Schrack[2,1], S. Stenholm[3], E.J. Metter[1], E.M. Simonsick[1,2], *1. National Institute on Aging, Baltimore, Maryland, 2. Johns Hopkins Medical Institutions, Baltimore, Maryland, 3. National Institute for Health and Welfare, Turku, Finland*

RMR is proportional to body size; higher in highly muscular and lower in fat individuals, but may become elevated with chronic disease as extra energy is needed to fight pathology. Theoretically, optimal RMR could be estimated from lean body and fat mass with levels beyond this estimate suggestive of excessive homeostatic effort. Using indirect calorimetry and DEXA data from 225 extremely healthy BLSA participants we derived estimates of disease-free RMR. Adjusting for age, lean body mass (kg) was strongly correlated with RMR in men (b=3.08RMR is proportional to body size; higher in highly muscular and lower in fat individuals, but may become elevated with chronic disease as extra energy is needed to fight pathology. Theoretically, optimal RMR could be estimated from lean body and fat mass with levels beyond this estimate suggestive of excessive homeostatic effort. Using indirect calorimetry and DEXA data from 225 extremely healthy BLSA participants we derived estimates of disease-free RMR. Adjusting for age, lean body mass (kg) was strongly correlated with RMR in men (b=3.08±0.82; p<.001) and women (b=4.42±0.86; p<.001). Fat mass (kg) was also independently correlated with RMR - strongly in men (b=3.79±0.88; p<.001) and weakly in women (b=1.27±0.66; p=.058). A significant interaction "muscle*fat" mass suggests that RMR per kg of lean mass is lower in obesity, possibly because of increased fatty infiltration of muscle. Estimating optimal RMR in older individuals requires assessment of both lean and fat parameters.

### WALKING SPEED AND ENERGETIC EFFICIENCY IN OLDER ADULTS

J. Schrack[1,2], E.M. Simonsick[2], P.H. Chaves[1], L. Ferrucci[2], *1. Epidemiology, Johns Hopkins School of Public Health, Baltimore, Maryland, 2. National Institue on Aging/National Institutes of Health, Baltimore, Maryland*

Walking speed declines with age and is predictive of negative health outcomes. With age, diminished biomechanical and metabolic efficiency may cause customary gait speed to slow in order to maintain optimal walking economy and conserve energy. To examine the relationship between walking efficiency (walking energetics) and usual walking speed, we measured: (1) the average energy expended per meter of walking (ml/kg/m) during 5 minutes of low-workload (0.67 m/s) steady-state treadmill walking, and (2) usual gait speed over 6 meters (m/s) in 382 (52% female) BLSA participants aged 50-96 (mean=70.6). Net efficiency (gross walking energy – resting energy) per meter of walking decreased significantly as walking speed declined (p<0.05) independent of age, sex, height, and ratio of fat-to-lean mass. These findings suggest that the energetic cost of walking increases with age, and that individuals slow down to conserve energy and maintain minimal energy cost at preferred speed due to reduced efficiency.

### IMPACT OF KNEE OA ON GAIT AND MECHANICAL WORK EXPENDITURE IN OLDER ADULTS: THE BLSA GAIT LAB

S. Ko, S.M. Ling, C. Schreiber, M. Nesbitt, L. Ferrucci, *NIH/NIA, Baltimore, Maryland*

Knee osteoarthritis (OA) is the most common age-related joint disease associated with mobility limitations. We evaluated specific gait patterns and mechanical work expenditure (MWE) during usual and challenging walking tasks in 153 BLSA participants (aged 53-87) classified as having symptomatic, asymptomatic, or no knee OA. Persons with knee OA walked slower with shorter stance compared to controls. For the fast walking task, those with asymptomatic knee OA used higher knee absorptive MWE (p = 0.012) and lower ankle generative MWE (p = 0.003) in the anterior-posterior (AP) plane compared to controls. Although mechanical energy usages in the AP plane for those with symptomatic knee OA were similar to no OA controls, the symptomatic knee OA group had a higher ankle range of rotation (p = 0.042). Whether these particular characteristics of gait increase the energetic cost of walking in persons with knee OA remains to be established.

### THYROID FUNCTION AND WALKING-RELATED PERFORMANCE AND ENERGETICS IN LATE LIFE

E.M. Simonsick[1,2], J. Schrack[2,1], L. Ferrucci[1], *1. National Institute on Aging, Baltimore, Maryland, 2. Johns Hopkins Medical Institutions, Baltimore, Maryland*

Recent findings indicate that older persons with mild subclinical hypothyroidism have moderately better mobility than those with normal thyroid function. We speculated that having a lower metabolic rate or "cooler engine" (lower free thyroxine; FT4) may explain this association. In 361 men (58%) and women aged 68+ years (mean=77.2) from the BLSA, we examined the relationship between FT4 and walking parameters including energy consumption during usual and fast paced corridor walks using a portable metabolic analyzer. Independent of sex, age, race, obesity, smoking and habitual walking behavior, increasing FT4 was associated with slower usual and rapid gait speeds (β=-.14, p=.013; β=-.26, p=.004), more seconds to walk 400m quickly (β=41.4, p=.008), and lower available energy measured as peak energy expenditure (ml/kg/min) during fast-paced endurance walking (β=-2.79, p=.016). Energy consumption per meter walked did not vary by FT4. Findings support the notion that having a "cooler engine" may sustain mobility with age.

## SESSION 545 (POSTER)

## ASSESSMENT, NUTRITION CONSIDERATIONS AND CHRONIC DISEASE MANAGEMENT

### SCREENING FOR INJURIOUS FALLS IN ACUTE CARE HOSPITAL

H.S. Sheth[1], K. Faust-Smith[2], R.M. Palmer[1,2], *1. Medicine, University of Pittsburgh, Pittsburgh, Pennsylvania, 2. University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania*

Background: Injurious fall is a serious hospital-acquired condition. Screening tools for injurious falls in hospitalized patients have received limited evaluation. Objective: To compare operating characteristics of University of Pittsburgh Medical Center (UPMC) injurious fall screen: mobility, fall history, nursing judgment (e.g., age, medications, recent surgery, confusion) with the ABCS tool[1] (age, bone, coagulation, surgery). Methods: Injurious fall patients were identified from the adverse events database for 2007-2008 admissions. A control group matched for age (>=65 and <65 years), location and time period of fall event was selected from administrative database. Both tools were evaluated by two independent screeners using electronic charts. Demographics, inter-rater agreement, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) are reported. Results: ABCS and UPMC injurious fall screens were applied to 43 fall patients and 43 matched controls. Both groups were similar in age, gender, race. Inter-rater agreement was 72% for UPMC and 71% for ABCS screens. ABCS and UPMC screens had sensitivity of 55.8% and 62.7%, and specificity of 41.8% and 60.4% respectively. PPV was 48.9% and NPV 48.6% for ABCS. PPV for UPMC was 60% and NPV 61%. The differences were not statistically significant. Conclusion: 50-60% of injurious falls can be predicted by one of these screens. The UPMC screen is promising but prospective studies are needed to verify the results. 1. Quigley PA. et al. Reducing serious injury from falls in two veterans' hospital medical-surgical units. Journal of Nursing Care Quality 2009; 24:33-41.

## THE CS-PFP10 MAINTAINS ROBUSTNESS IN FIT, COMMUNITY DWELLING OLDER AND YOUNGER INDIVIDUALS WHEN COMPARED WITH THE SPPB

W.C. Logan[1], J.O. Brooks[2], M. Cress[3], *1. Geriatrics, Palmetto Health, Columbia, South Carolina, 2. Clemson University, Clemson, South Carolina, 3. University of Georgia, Athens, Georgia*

Introduction: Several physical function and mobility measures have been developed and validated for use with community dwelling populations; these include the Continuous Scale Physical Functional Performance 10 test (CS-PFP10) and the Short Physical Performance Battery (SPPB). Both instruments have been well validated. This study was designed to evaluate the performance of the CS-PFP10 and the SPPB in community dwelling older and younger individuals. Methods: Both the CS-PFP10 and the SPPB were completed by 249 college students (mean age 19.4 ± 2.3SD years) and 162 community dwelling elders (mean age 60.4 ± 8.5SD years). Results: The SPPB mean summary scores were similar for both groups (11.5 ± 0.9SD in elders, 11.9± 0.1SD in students). The mean CS-PFP10 total scores were significantly different (means 60.4 ± 13.6SD for elders and 72.2 ± 9.8SD for students, Student's t-test p<0.0001). The CS-PFP10 score was distributed normally while the SPPB summary score was a kurtosis distribution, limited by a 12-point ceiling. Conclusion: The SPPB was limited by ceiling effect in these community dwelling populations. The CS-PFP10 covers a broad range of ability - low to high functioning individuals. Further study will assess the implications of higher or lower CS-PFP10 scores in healthy populations. Being able to discriminate apparently healthy individuals at risk for future limitations may allow early intervention to protect from future disability.

## USUAL GAIT SPEED BEST PREDICTS CS-PFP10 SUMMARY SCORES IN COMMUNITY DWELLING YOUNG PEOPLE AND ELDERS

W.C. Logan[1], J.O. Brooks[2], M. Cress[3], *1. Geriatrics, Palmetto Health, Columbia, South Carolina, 2. Clemson University, Clemson, South Carolina, 3. University of Georgia, Athens, Georgia*

Introduction: Identifying healthy individuals who may be at risk for future disability is challenging. Both the short physical performance battery (SPPB) and usual gait speed have been identified as frailty markers in elders. Both have been proposed as screening tests to identify those who might need more robust testing, like the Continuous Scale Physical Functional Performance 10. This study was designed to evaluate the performance of SPPB and gait speed in relation to the CS-PFP10. Methods: The CS-PFP10, usual gait speed and the SPPB were completed by 248 young (mean age 19.4±2.26SD yr) and 162 older (mean age 60.4 ±8.47SD yr) individuals. Linear regression modeling was used to evaluate how well gait speed and SPPB summary scores predict CS-PFP10 total scores. Results: Adjusted for age, sex and body mass index (BMI), only usual gait speed (1.1±0.42SD m*s-1 in younger, 1.2±0.20SD m*s-1 in older participants) was a consistent, strong predictor of CS-PFP10 scores in both elders (60.4±13.6SD p<0.001) and young volunteers (72.2±9.85SD p=0.01). Conclusion: Usual gait speed is a good measure to predict physical performance on comprehensive functional measures like the CS-PFP10. Gait speed is inexpensive, simple to perform, and may identify individuals at risk for disability. Further research is needed to evaluate the utility of gait speed as a screening method to identify those at risk for loss of independence where evaluation with CS-PFP10 might yield more detailed information.

## WANDERING AWAY RISK ASSESSMENT IN HOSPITALIZED PATIENTS

H.S. Sheth[1], D. Krueger[2], S. Bourdon[2], R.M. Palmer[1,2], *1. Medicine, University of Pittsburgh, Pittsburgh, Pennsylvania, 2. University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania*

Background: Hospitalized patients with impaired cognition are at risk of "wandering away" (WA). The appropriateness of tools to identify hospitalized WA patients is not known. UPMC Presbyterian hospital created an electronic health record (EHR)-based WA risk assessment tool linked to interventions that are implemented by floor nurses. Aim: To evaluate the appropriateness of WA risk assessment and prevention interventions by the floor nurses. Methods: Consecutive series for 3 weeks of patients who screened positive by floor nurses for WA risk. Two expert advanced practice nurses (APN) performed EHR and bedside evaluation of appropriateness of positive screen and interventions. WA risk was defined as cognitively impaired and mobile, or nursing judgment. Results: APNs evaluated 81 patients with WA positive risk: 43(43.2%) females, mean age 64.9 yrs (16-92 years), 43 (53%) >=65 years, 8 (9.9%) AA; 33 % medical, 43% surgical, 16% trauma, 8% ICU; 13(16.1%) dementia and 58 (70.7%) impaired cognition. 37/81 (45.7%) patients were assessed appropriately (positive WA risk). 34/81 (42 %) patients were incorrectly documented in EHR but subsequently corrected. 10/81 (12.3%) patients were incorrectly assessed by the floor nurse. Appropriate interventions were implemented for 33/37 (89.2%) WA risk patients, while APN intervened in remaining 4 patients. 10/37 (27%) patients' risk status ameliorated before transfer/discharge, 2 identified by APN. Conclusion: The wander away risk assessments by floor nurses were accurate (71/81, 87.7%). APNs were valuable in ensuring appropriate interventions (4/37; 10.8%), changing risk status (2/37; 5.4%) and identifying incorrectly labeled positive risk patients (10/81; 12%).

## A COMPARISON OF QUALITY-RELATED PROCESSES OF CARE FOR MEDIGAP INSUREDS WITH AND WITHOUT FULL FIRST DOLLAR OUT-OF-POCKET PAYMENT COVERAGE

K. Hawkins[1], G.R. Bhattarai[1], R.J. Ozminkowski[3], R.J. Migliori[3], C. Yeh[2], *1. Ingenix, Ann Arbor, Michigan, 2. AARP Services Inc., Washington, District of Columbia, 3. UnitedHealth Group Alliances, Ann Arbor, Michigan*

Research Objectives: To compare quality-related processes of care between Medigap insureds with and without full first-dollar payment coverage. Study Design: Adherence to evidence-based medicine (EBM) measures of care processes was measured for members with AARP® Medicare Supplement Health Insurance (i.e., Medigap) plans underwritten by UnitedHealthcare. Medigap plans that cover deductibles for Medicare Parts A and B are often referred to as full first-dollar coverage plans and include plan types C, F and J. Adherence rates for Medigap insureds in these plans were compared to rates for insureds in Medigap plans without full first-dollar coverage. Data on 161 EBM measures pertaining to adults age 65 and older were used in the analysis. These measures covered medical or pharmaceutical treatment for common chronic conditions. For each measure, a logistic regression model estimated adherence related to plan type, controlling for patient demographics and health status. Population Studied: About 2.8 million Medigap insured were included in the analyses. Principle Findings: When considering only EBM measures where statistically significant (p<0.05) differences existed, individuals in full first-dollar coverage plans had higher rates 86% of the time. However, when we applied a notion of "practical significance" by assuming adherence rates must differ by more than 5% to be meaningful, the EBM adherence rates were similar for those with and without full first-dollar coverage. Conclusions: Full first-dollar coverage plans accounted for 63% of the sample, so while the actual percentage increases in adherence may be small, the potential for impacting many numbers of beneficiaries may be large.

### AN EXPLORATION OF MEDICATION ADHERENCE AMONG INDIVIDUALS WITH HIV

T. Davis, S.N. Munk, F. Zanjani, *Gerontology, University of Kentucky, Lexington, Kentucky*

Older adults often are required to take numerous medications, and having HIV increases that burden. For individuals with HIV, adherence to medication regimens is especially important to the success of drug therapy and can perhaps delay transitions in care. The purpose of this secondary data analysis was to explore the difference in HIV medication adherence in older adults as compared to younger adults. Specifically, we sought to identify factors that differentially contribute to medication adherence among 109 participants (young= 21-49, and old=50-88) from the University of Pennsylvania Center for AIDS. We hypothesized that medication adherence would be influenced by social support, apathy, and/or sleep (as measured by the Duke Social Support index, the Apathy Scale, and the Medical Outcome Sleep Scale, respectively) and that older adults would be less adherent to their HIV medication regimens (as measured by the HIV Medication Adherence Measure). We conducted chi-squares and ANOVAs to assess the relationship among these variables, using SAS 9.1. The results indicate that older adults are more likely to be adherent and that social support, apathy, and sleep do not significantly impact medication adherence in this sample. Further research is needed to better understand medication adherence among older adults with HIV. If it is the case that older adults with HIV are more likely to be adherent to their medications, then perhaps we can take what we learn from older adults with HIV and increase medication adherence among other groups.

### PAIN HURDLES IN LONG TERM CARE: A LITERATURE REVIEW

S.G. Robinson, *1. Wayne State University, Detroit, Michigan, 2. Hospice of Michigan, Detroit, Michigan*

Chronic pain is a significant problem that affects the quality of life of institutionalized elders. Much research has been completed linking chronic pain to psychological distress and overall patient declines. Of particular concern within the long term care (LTC) industry is the need to address pain control within a highly regulatory environment, despite a variety of patient, practitioner, and institutional barriers preventing progress. An evaluation of peer-reviewed articles published in the last decade was completed to identify pain management barriers and best practices. Using EBSCOhost Database search terms “pain” and “long term care” were used to isolate 27 English, peer-reviewed articles published from January 1999 to November 2009 that specifically addressed barriers and best practices of pain management LTC. The most common types of pain management barriers present in LTC facilities may be categorized into three major groups including personal, institutional, and professional. Common themes to improve programming included: increasing knowledge of patients, families, and practitioners regarding pain and pain treatments, increasing interdisciplinary involvement in the pain management process, and setting both measureable and achievable goals. As patient advocates with expertise in human science and health, nurses are best prepared to further the body of work in chronic pain—specifically by identifying whether or not chronic pain is the most significant factor in quality of life for institutionalized elders as well and what quality of life factors may need to be addressed prior to or in conjunction with pain control issues.

### THE IMPACT OF MEDICATION USE AND MEDICAL MORBIDITY ON SYMPTOM BURDEN IN OLDER PATIENTS

M.A. Han, L.M. Walke, M. Tinetti, *Yale University School of Medicine, New Haven, Connecticut*

Background: Older patients have more medical morbidities, consume a greater number of prescribed medications, and report lower levels of quality of life than their younger counterparts. Symptom burden directly contributes to the physical component of quality of life; thus, factors associated with symptom burden may influence perceived quality of life. Objectives: To determine whether there is 1) an association between medical morbidity and symptom burden or 2) an association between medication use and symptom burden. Methods: This cross-sectional study included 159 community-dwelling male patients who were 65 years of age or older. Correlations were drawn using linear regression analysis. Results: On average, the participants in this study had 2.56 +/- 1.36 medical morbidities, were prescribed 7.91+/- 2.83 medications, and reported 3.17 symptoms at any severity level. We found a direct correlation between the number of medical morbidities and symptom burden (R2 = 0.94) but did not find a significant correlation between medication use and symptom burden (R2 = 0.20). Conclusions: Our results suggest that the number of medical morbidities has a stronger negative impact on symptom burden than the number of medications used. Efforts to improve quality of life for older patients may prove more successful if increased attention is paid to the treatment and alleviations of symptoms associated with medical morbidity.

### SUBOPTIMAL LABORATORY MONITORING OF CHRONIC MEDICATIONS IN OLDER VETERANS ADMINISTRATION NURSING HOME PATIENTS

S.M. Handler[1,2], X. Wang[2], S.L. Aspinall[2], R.A. Stone[2], M. Pugh[3], T. Semla[4], J.T. Hanlon[2], *1. Biomedical Informatics, University of Pittsburgh, Pittsburgh, Pennsylvania, 2. VA Healthcare System, Pittsburgh, Pennsylvania, 3. VA VERDICT, San Antonio, Texas, 4. VA PBM, Hines, Illinois*

Objective: To estimate the prevalence and identify factors associated with suboptimal laboratory monitoring of certain chronic medications prescribed to older Veterans Administration (VA) Nursing Home Care Unit (NHCU) patients. Design: Longitudinal study. Setting: 133 VA NHCUs. Participants: Cohort of 1,059 patients ≥ 65 years old, admitted between January 1, 2004 and June 30, 2005, who were prescribed ≥ 1 of the 9 chronic oral medications of interest for a period of ≥ 90 days. Main Outcomes Measure: Frequency of suboptimal laboratory monitoring of these chronic medications defined as less than that recommended by consensus guidelines developed by a national panel of nursing home clinicians. Results: Overall, 19.0% (201/1,059) of patients had suboptimal laboratory monitoring for chronic medications of interest. Few (26/201) had problems with ≥ 2 medications. Narrow therapeutic index medications commonly had suboptimal laboratory monitoring (i.e., 53.6% for theophylline, 26.5% for warfarin, 20.0% for lithium, 17.5% for phenytoin, and 14.3% for valproate). Suboptimal laboratory monitoring was also common for NSAIDs (39.1%) and corticosteroids (16.2%). Fewer laboratory monitoring problems were seen with diuretics (10.0%) or ticlopidine (0%). Only patients ≥ 85 years old (Adj. OR 0.52; 95%CI 0.31-0.88), and those who were prescribed ≥ 13 medications (Adj. OR 0.49; 95%CI 0.31-0.78) were less likely to have suboptimal laboratory monitoring. Conclusions: Suboptimal laboratory monitoring of medications is common in VA NHCU patients and frequently involves narrow therapeutic index medications. Future research is needed to estimate the association between suboptimal laboratory monitoring on health outcomes.

### EFFECTS OF BMI ON QUALITY OF LIFE AMONG RACIAL SUBGROUPS WITH CHRONIC MEDICAL CONDITIONS

M.J. Huisingh-Scheetz, S. Bilir, W. Dale, *University of Chicago, Chicago, Illinois*

Background: Obesity decreases health-related quality of life (HRQOL) independent of age and associated chronic medical conditions. It is unclear how race/ethnicity affects this relationship. We analyzed how race/ethnicity impacts the impact of Body Mass Index (BMI) on HRQOL, accounting for chronic medical conditions (CMC). Methods: The Chicago-based Improving Community Health Survey (2002-2003) collected self-reported health information and over-sampled for minorities. BMI was calculated for each participant. HRQOL was measured using scores from the validated SF-12 questionnaire. We used multivariate linear regression to assess the relationship of BMI to HRQOL. After stratifying by race/ethnicity, models were adjusted for age, gender, income, and education, and then were compared to models further adjusted for CMC (arthritis, asthma, diabetes, hypertension, heart problems) and smoking status. Results: Data from 324 non-Hispanic whites, 742 non-Hispanic blacks, and 546 Hispanics were included. Increasing BMI was associated with poorer physical HRQOL similarly among subgroups (B= -0.36, H= -0.38, W=-0.31, $p \le 0.05$). After adjusting for CMC and smoking, this relationship remained significant only among blacks and Hispanics (B= -0.20 and H= -0.31, $p \le 0.05$; W=-0.13, $p > 0.05$). Increasing BMI was significantly associated with poorer mental HRQOL only among whites. After adjusting for CMC and smoking, this relationship was no longer significant (B= -0.04, H= -0.0001, W=-0.16, $p > 0.05$). Discussion: Controlling for age and CMC, overweight/obese minorities have worse physical HRQOL than whites, but no worse mental HRQOL. Future studies investigating this disparity are needed to better understand the impact of obesity on minority HRQOL.

### THE ASSOCIATION BETWEEN HEALTHY EATING INDEX-2005 AND GAIT SPEED AMONG OLDER AMERICANS

B. Xu, C. Zizza, *Auburn University, Auburn, Alabama*

Although nutritional status is one of the major determinants of successful aging, the relationship between overall diet quality and physical functioning among older adults has not been previously examined. Using data from the 1999-2002 National Health and Nutrition Examination Survey, we examined the association between overall diet quality, measured by USDA's Healthy Eating Index-2005 (HEI-2005), and gait speed over 20 feet, a performance-based measure of physical functioning, in 3,380 adults (≥ 50 years old). The HEI-2005 assesses compliance with dietary recommendations over a range of food- and nutrient-based components including total fruit; whole fruit; total vegetables; dark green and orange vegetables and legumes; total grains; whole grains; milk; meat and beans; oils; saturated fat; sodium; and calories from solid fats, alcoholic beverages, and added sugars (SoFAAS). The 12 individual components are summed to yield the HEI-2005 scores ranging from 0 to 100, with a higher score indicative of a more health promoting diet. A multiple linear regression model controlling for age, gender, race/ethnicity, education, smoking status and marital status was used. Compared to those older adults with HEI-2005 scores in quartile 1, there was a 0.03 meters/second increase ($P = 0.035$) for those with HEI-2005 scores in quartile 3 and a 0.04 meters/second increase ($P = 0.009$) for those with HEI-2005 scores in quartile 4. The clear association between overall diet quality and physical functioning suggests adherence to dietary recommendations among older adults should be endorsed.

### AN HERBAL LOLLIPOP FOR ORAL CARE IN NURSING HOME RESIDENTS

J. Mentes[1], S. Kang[1], S. Spackman[2], J. Bauer[2], *1. UCLA Center for the Advancement of Gerontological Nursing Science, Los Angeles, California, 2. UCLA School of Dentistry, Los Angeles, California*

Oral bacteria can cause dental caries and systemic infections in older adults. The purpose of this pilot study was to examine whether an herbal lollipop containing licorice root decreases streptococcus mutans bacteria that cause cavities and respiratory infections in older adults. Two nursing homes in the greater Los Angeles area were utilized as the setting for this study. A total of 9 participants, 3 men and 6 women, with a mean age of 85 years consented to participate in this pilot study. The participants were given two lollipops a day for 21 days. Saliva samples were collected at baseline and days 1, 3, 7, 14 and 21 then analyzed for the numbers of streptococcus mutans. Participant's teeth, gums and mucus membranes were examined for overall condition at baseline and follow up. Using linear mixed models analysis with difference in numbers of strep mutans from baseline to any time point as the dependent variable, and number of lollipops consumed with the effect of time controlled as the predictor variable, participants who consumed more lollipops over the 21 day time period were more likely to have fewer numbers of strep mutans ($\beta = -8.703$, $p=0.067$). There was a trend toward reduction of Streptococcus mutans with consumption of more lollipops over the 21-day period and an improvement in the condition of the participant's teeth and gums on examination. Recruiting a larger sample may demonstrate significant reductions in bacteria and further improvement in dental status.

### ORAL HEALTH AND AGING: COMMUNITY-UNIVERSITY PARTNERSHIPS FOR HEALTH, EDUCATION, AND RESEARCH

L. Tepper, *1. Columbia University, New York, New York, 2. Mercy College, Dobbs Ferry, New York*

Project Elder Smile is a university-community partnership sponsored by grants from private foundations which seeks to promote improved health care services for the medically underserved members of urban communities. The College of Dental Medicine at Columbia University is engaged in an innovative outreach program in northern Manhattan, which seeks to improve the oral health care status of older minority elders within these communities. ElderSmile has provided a series of interative educational presentations about aging and oral health, and free dental screenings by dental school faculty and students in each of their four years of dental school to over 600 older residents of public housing units and senior centers within these neighborhoods. These screenings are followed by free treatment in four community dental clinics including the College of Dental Medicine. This presentation will discuss the rationale, development, protocol, and evaluation of this three-year program, an analysis of the oral health needs of this population, and suggestions and recommendations for the establishment of similar university-community partnerships that promote improved oral health for medically and dentally underserved minority elders.

## SESSION 550 (SYMPOSIUM)

### BIOMARKERS OF PRESERVED NEUROLOGICAL FUNCTION

Chair: *C. Rosano, University of Pittsburgh, Pittsburgh, Pennsylvania*
Discussant: *L. Lipsitz, Institute for Aging Research, Boston, Massachusetts*

Preserved neurological function is a key factor to maintain independence late in life. There is preliminary evidence that inflammatory and cardiometabolic factors are associated with neurological changes in the elderly. Exposure to these factors may cause subclinical structural changes in the central and peripheral nervous systems, which in turn impair function and lead to disability. The goal of this symposium is to identify the factors related to preserved neurological function in older adults. The discussants will utilize integrated neuroepidemiological approaches to characterize protective and at-risk factors in the context of multiple neurological domains. Data from four large longitudinal cohort studies will be presented: Cardiovascular Health Study, Health, Aging and Body Composition Study, Rush Memory and Aging Project and Mobilize Boston. Understanding the determinants of preserved neurological function may help identifying new targets for intervention and preventive strategies and thus reduce the burden of disability in older adults.

### RESILIENCE TO BRAIN AGING: A SECOND LOOK

C. Rosano, L.H. Kuller, A.B. Newman, *University of Pittsburgh, Pittsburgh, Pennsylvania*

One hypothesis to explain why older people remain high functioning late in life is that they have a greater "brain reserve". However, brain reserve has not been objectively quantified, as it has mostly relied on gross measures of whole-brain abnormalities that are largely non specific manifestation of brain aging. Additionally, the determinants of brain reserve have not been characterized systematically, in relationship to objective measures of brain integrity. We propose to identify the main biomarkers of brain reserve by using longitudinal extensive data on risk factors in a sub-cohort of older adults participants of the Cardiovascular Health Study at the Pittsburgh field site, followed from 1994 through 2004-05. We define brain reserve using objective quantitative measures based on repeated brain magnetic resonance imaging.

### DO TRADITIONAL OR NON-TRADITIONAL RISK FACTORS FOR NEUROPATHY PREDICT NERVE FUNCTION DECLINE IN OLDER ADULTS?

E.S. Strotmeyer[1], R. Boudreau[1], S. Zivkovic[1], A.I. Vinik[2], A.V. Schwartz[3], S. Satterfield[4], T.B. Harris[5], A.B. Newman[1,6], *1. Epidemiology, University of Pittsburgh, Graduate School of Public Health, Pittsburgh, Pennsylvania, 2. Eastern Virginia Medical School, Norfolk, Virginia, 3. University of California, San Francisco, San Francisco, California, 4. University of Tennessee Health Science Center, Memphis, Memphis, Tennessee, 5. National Institute on Aging, Bethesda, Maryland, 6. University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania*

Peripheral nerve impairments occur with aging. Diabetes is a major risk factor but does not entirely explain age-related impairments. We evaluated the association of traditional (age, diabetes, height, alcohol use, smoking) and non-traditional (IFG, subclinical vascular disease, high lipids, renal function) factors to greater sensory and motor nerve declines in Health ABC (N=3075 well-functioning persons, 70-79 years in 1997-98). Vibration threshold (sensory) and peroneal nerve conduction velocity and amplitude (motor) were assessed in 2000-01 and 2007-08 (N=1017; 52.9% women, 32.5% black; 76.0±2.7 years; 18.5% diabetes). With adjustments including baseline nerve function, baseline diabetes, taller height and high cystatin-C predicted greater motor nerve decline. Older age and taller height predicted greater sensory nerve decline. Subclinical vascular disease or incident diabetes/IFG was not related to decline. Largely traditional risk factors predicted peripheral nerve decline. Older age remained important for sensory nerve decline but the relationship with motor nerve decline was attenuated.

### HYPERTENSION AND COGNITIVE FUNCTION: ROLE OF THE RENIN ANGIOTENSIN SYSTEM

I. Hajjar[1], V. Novak[2], L. Lipsitz[1], *1. Institute for Aging research, Hebrew SeniorLife, Boston, Massachusetts, 2. Beth Israel Deaconess Medical Center, Boston, Massachusetts*

We present findings, suggesting that the renin angiotensin system (RAS) presents a potential biomarker for the impact of hypertension on cognitive function. We demonstrated using arterial spin labeling MRI that hypertension was associated with low perfusion and impaired ability to respond to CO2, a measure of cerebral vasomotor reserve. Both linked to cognitive impairment. We reported that a polymorphism (M235T) in the gene that code angiotensinogen was associated with CO2 vasoreactivity and that M235T is also related to decline in executive function. Higher levels of RAS biomarkers were also associated with worse executive function. Treatment with angiotensin converting enzyme inhibitors (ACEI) was associated with slower cognitive decline and Alzheimer's disease progression and improved cerebral blood flow. Finally, the M235T polymorphism modified the cognitive outcome of treatment with ACEI. Evidence is accumulating that RAS activity, through its cerebrovascular role, maybe a biomarker for the risk of cognitive impairment in hypertension.

### ASSOCIATION OF HEMOGLOBIN AND NEUROPATHOLOGY: A COMMUNITY COHORT, CLINICAL-PATHOLOGY STUDY OF AGING

R.C. Shah, J.A. Schneider, S. Leurgans, D. Bennett, *Rush University Medical Center, Chicago, Illinois*

Background: How hemoglobin links to neuropathology associated with cognitive function in older persons is uncertain. Methods: Hemoglobin and neuropathology measures were available for 113 deceased Rush Memory and Aging Project participants. Neuropathology assessment included an Alzheimer's disease (AD) pathology summary score of amyloid plaque and neurofibrillary tangle counts along with presence of gross infarcts, microscopic infarcts, or Lewy Bodies. Results: Mean AD pathology score was 0.56 unit (SD=0.56; range=0, 2.34). Thirty-five, twenty-nine, and eleven participants had gross infarcts, microscopic infarcts, or Lewy Bodies. Mean hemoglobin level was 13.0 g/dL (SD=1.4). In a multiple regression model, hemoglobin was not associated with AD pathology (parameter estimate=-0.02, SE=0.03, p=0.55). Using logistic regression models, each g/dL decrease in hemoglobin increased odds for having gross infarcts by 39% (95% CI=1.03-1.87) but not microscopic infarcts (OR=1.15, 95% CI=0.85-1.55) or Lewy Bodies (OR=1.09, 95% CI=0.70-1.70). Conclusion: Lower hemoglobin is associated with gross infarcts but not other neuropathology.

## SESSION 555 (PAPER)

## DIRECT CARE WORKER PRACTICE IN RESIDENTIAL CARE FACILITIES

### SUPPORTING MEMORY AND COMMUNICATION IN PEOPLE WITH DEMENTIA: AN EDUCATIONAL PROGRAM FOR CAREGIVERS

M. Broughton, E.R. Smith, R. Baker, N.A. Pachana, A.J. Angwin, G. Byrne, M.S. Humphreys, H.J. Chenery, *University of Queensland, Brisbane, Queensland, Australia*

Background: Strategies to support memory and communication function in people with dementia are important. However, cognitive rehabilitation approaches are often overlooked within the framework of a largely medical approach to dementia, particularly in residential care. We designed DVD-based educational programs entitled RECAPS and MESSAGE, encapsulating sets of straightforward, evidence-based strategies to assist caregivers in maximising everyday memory and communication abilities, respectively, in people with dementia. Method: 60 caregivers from residential aged care facilities participated in a trial of RECAPS and MESSAGE. Of these caregivers, 38 also completed questionnaires assessing knowledge of strategies for supporting memory and communication in dementia at baseline, and immediately after training. Results: Results from an evaluation survey of the utility of the programs were positive. Specifically, 97% considered the information useful; 92% thought the strategies would not be difficult to apply in everyday life; 94% would definitely recommend the training to a colleague or friend; and 74% reported that they had learned a lot from the program. Caregivers demonstrated a significant increase in their knowledge of strategies to support memory and communication post-training (p = .001). Discussion: Initial results indicate that professional caregivers find the RECAPS and MESSAGE strategies clear, practical and easily applied in the residential aged care environment. Furthermore, the program significantly enhanced caregiver knowledge. Future development of the materials, incorporating consumer feedback, will focus on web-based dissemination to allow wider access to the program. This has the potential to lead to sustainable changes in practice in these important aspects of dementia care.

### WORK STRESS AND INTENTION TO QUIT THE JOB AMONG DIRECT CARE WORKERS: DO WORK SOCIAL SUPPORT AND LOCUS OF CONTROL MAKE A DIFFERENCE?

J. Gray-Stanley[1], N. Muramatsu[2], *1. Public Health & Health Education, Northern Illinois University, Dekalb, Illinois, 2. University of Illinois at Chicago, Chicago, Illinois*

Direct care workers (DCWs) provide substantial services for adults with intellectual and developmental disabilities (ID) by assisting with basic needs and facilitating independent living. Though work stress has been shown to limit these capacities and contribute to turnover, the external resources of work social support and the internal resources of an internal locus of control can help DCWs work more actively. We examined if work stress affects intentions to quit the job, and whether these resources can lessen the effects of work stress on plans to exit the workplace. DCWs (n = 323) serving adults with ID from 5 community-based organizations which provide residential, vocational, and personal/respite/foster care services completed a cross-sectional, self-administered survey. Multiple regression analyses then examined the main and moderating effects of work support and locus of control on intent to turnover. Work stress was positively associated and work social support was negatively associated with intentions to quit. Interestingly, the effects of an internal locus of control depended on how DCWs perceived their participation in work-related decision making. Among those perceiving limited participation, an internal locus of control had a negative association with intention to quit; however, among those perceiving more participation, locus of control had no effect. While work support may deter some workers from quitting, internal control beliefs may help DCWs who perceive limited participation in decision-making. Such findings suggest the importance of work support and teamwork development for all DCWs, as well as their participation in decision-making processes.

### INTEGRATING EXERCISE INTO HEALTH CARE AIDES' PRACTICE: MOBILITY OF VULNERABLE ELDERS (MOVE)

S. Slaughter, C. Estabrooks, *University of Alberta, Edmonton, Alberta, Canada*

Introduction: Several rehabilitative approaches involving dedicated research assistants or highly trained health care aides have been tested in long-term care (LTC) settings. Such approaches are unlikely to be adopted or sustained in the resource constrained environments of LTC facilities. Objective: The purpose of this study was to evaluate a knowledge translation intervention (reminder system) to integrate a simple mobility activity (repeating sit-to-stands) into the routines of health care aides. Methods: This ethnographic study was conducted in two LTC facilities. We gathered data through non-participant observation data before and after the introduction of the sit-to-stands, semi-structured interviews, adherence questionnaires, and health record documentation. We compared data from the various sources to understand the process factors associated with the uptake of the sit-to-stands. Results: The documentation flowsheet reminded everyone, 66% benefited from visual reminders in residents' rooms, and few benefited from posting resident participant names. Everyone agreed that the activity was a good idea but identified barriers to completing the sit-to-stand activity both for themselves and the residents. Factors influencing performance included time availability, knowing residents well enough to elicit their cooperation, and residents' willingness to participate. Health care aides described strategies to persuade the residents to exercise: explaining, making it a game, using music, encouraging competition, avoiding distracting locations, and providing one-step instructions. Conclusions: It is possible to integrate sit-to-stand repetitions into the daily practice of health care aides and residents. We plan to assess other methods (interactive education, and audit and feedback) to facilitate the adoption of this mobility innovation.

### DEVELOPMENT OF A MENTAL HEALTH-RELATED TRAINING FOR ASSISTED LIVING FACILITY DIRECT CARE STAFF

E.K. Dakin, *School of Social Work, Colorado State University, Fort Collins, Colorado*

In addition to already high rates of depression, a Medicaid Mental Illness waiver in Colorado has led to a rising number of persons with mental illness as a primary diagnosis residing within assisted living facilities (ALFs). Reflective of changes such as Medicaid waivers providing for non-nursing home placements, it is believed that ALFs will increasingly be serving a resident population contending with complex mental health diagnoses such as depression, dementia complications, various anxiety disorders, and schizophrenia (Bartels, 2001). The growing level of mental health concerns and the co-housing of frail elders and persons with severe mental illness create many challenges for ALF staff. A mental health-related training module and associated knowledge test for direct care staff was developed and pilot-tested based on results of a needs assessment that examined the education and training histories and perceptions of mental health training needs among ALF administrators and direct care staff in Larimer County, CO . This module focuses on the development of specific skills related to difficult behaviors, the development of empathy for causes of difficult behavior, exploration of myths related to mental illness, and stresses the importance of self-care and self-awareness of triggering people and behaviors. The training and knowledge test were pilot-tested and further refined based on feedback from focus groups and a community advisory board. The knowledge test was also refined based on frequency analysis of its questions. Further testing of the training and knowledge test using an experimental design are the next phase for this project.

## SESSION 560 (PAPER)

## INTERNATIONAL PERSPECTIVES ON DISABILITY & MOBILITY

### SENSORY-MOTOR AND PSYCHOSOCIAL DETERMINANTS OF ADAPTIVE LOCOMOTOR PERFORMANCE: THE INCHIANTI STUDY

N. Deshpande[1], E. Metter[2], L. Ferrucci[2], *1. Queen's University, Kingston, Ontario, Canada, 2. National Institute on Aging, NIH, Baltimore, Maryland*

The ability to adapt basic locomotor pattern to suit environmental challenges is critical for mobility. However, factors associated with efficacy of adaptive locomotor performance (ALP) are not known. This study identified sensorymotor and psychosocial determinants of ALP under different challenges and examined differences in ALP between older persons with and without self-reported mobility disability. Cognitively intact 1060 InCHIANTI participants (age:21-98 years) who could walk 7 mt were included. Four challenging conditions were administered: 1.walking on a narrow path, 2.crossing an obstacle while walking, 3.walking while performing a cognitive verbal task and 4.walking as fast as possible. Walking speed represented global ALP. The sensorymotor and psychosocial parameters included vision and lower limb somatosensory impairment, knee extensor strength, lower limb coordination, depression, cognition, personal mastery, social support and education. Backward linear regression models revealed two primary determinants ($P<0.05$) with highest relative weighting as follows: condition 1:vision and knee strength, condition 2:vision and somatosensory impairment, condition 3:knee strength and cognition and condition 4: knee strength and coordination. The walking speed of the elderly with mobility disability was significantly slower ($p<0.05$) in all 4 conditions even after adjusting for normal walking speed and age, however, the effect size was highest for fast walking followed by walking on a narrow path that increased demands on medio-lateral stability. In conclusion, determinants of adaptive locomotor performance are specific to the challenge induced. Elderly with self-reported mobility disability possibly have more difficulty for increasing walking speed on demand and when demands on medio-lateral body stability are increased.

### ACTIVITIES OF DAILY LIVING AND HEALTH STATUS OF THE ELDERLY IN KOREA

M. Park, J. Ha, *College of Nursing, Keimyung University, Daegu, Republic of Korea*

This study analyzed data from the 2008 national study of Korean elderly to investigate health status according to activities of daily living of the elderly in Korea. The 2008 national study of Korean elderly surveyed 15,146 elderly people (Male: 6,452, Female: 8,694) over 60 years who were living in community and investigated their health and economic condition, and welfare status. This study focused on their chronic disease, perceived health status, depression, fall, and physical function according to ADL and IADL status. About 23% of the Korean elderly had disabilities on one or more ADL and IADL items and the disability rate significantly grows higher according to age. The number of chronic disease was positively correlated with the disability on ADL and IADL. Increased number of disability on the ADL & IADL appeared to be associated with negative perceived health status. The elderly who met the depression criteria had higher disability rate on ADL and IADL. The number of fall was more frequent and the fear of falling was higher among the elderly who had disability on one or more ADL and IADL items. There are also a definite correlation between physical function and activities of daily living: the upper, lower, and total physical functions were significantly different according to the degree of disability on ADL and IADL. This study supports that evaluation on the elderly people's ADL and IADL is very important to estimate their physical and emotional health status.

### EDUCATIONAL GAP IN LIFE EXPECTANCY AND DISABILITY-FREE LIFE EXPECTANCY AMONG OLDER ADULTS IN SãO PAULO, BRAZIL

F. Andrade[1], P.E. Guevara[1], M.L. Lebrão[2], J.L. Santos[3], *1. Kinesiology and Community Health, University of Illinois at Urbana-Champaign, Champaign, Illinois, 2. Universidade de Sao Paulo, Sao Paulo, Sao Paulo, Brazil, 3. Universidade de Sao Paulo, Ribeirao Preto, Sao Paulo, Brazil*

Objectives: The aim of the present study is to investigate the relationship between socioeconomic (SES) status, measured by education, and total life expectancy (TLE), disability-free life expectancy (DFLE), disabled life expectancy (DLE). Methods: The sample was drawn from two waves of the Survey on Health and Well-being of the Elderly (SABE), which followed 2,143 older adults from 2000 to 2006 in São Paulo, Brazil. Disability was assessed through Activities of Daily Living (ADL) measure. Education was assessed based on literacy status. The Interpolation of Markov Chains method was used to estimate the impact of education on TLE and DFLE. Results: Among individuals aged 60 and over in São Paulo, 25.5% were illiterate in year 2000. Illiteracy rates are higher among women than among men (29.6% and 19.6%, respectively) ($p<0.0001$). Illiteracy was associated with higher disability prevalence (32.1% versus 20.7% among those who are literate) ($p<0.0001$). TLE at age 60 reached 19.8 years (95% CI: 18.0-21.6) among those who are literate and 17.2 years (95% CI: 16.1-18.2) among those who are illiterate. There are significant SES differentials in DFLE, but small differences are found in DLE. At age 60, DFLE is estimated in 15.3 years (95% CI: 13.7-16.8) among those who are literate and 12.5 years (95% CI: 11.6-13.4) among those illiterate. Discussion: Among older adults in Brazil, higher education is associated with longer TLE and DFLE. A positive SES gradient in TLE and DFLE was found for both males and females in São Paulo, Brazil.

### ADL AND IADL DISABILITY TRENDS IN SHANGHAI OLDER ADULTS, 1998 TO 2008

Q. Feng[1], D. Gu[2], Z. Zhen[3], Z. Xiong[3], P.W. Duncan[1], J. Purser[1], *1. Medicine-Geriatrics, Duke University Medical Center, Durham, North Carolina, 2. United Nations - Population Division, New York, New York, 3. Shanghai University for Finance and Economics, Shanghai, China*

Background: Few studies document disability trends of older adults in developing societies. Objectives: This study estimated ADL and IADL disability trends for older adults in Shanghai (the most aged city of China) from 1998 to 2008, and how this time trend was influenced by selected risk factors. Methods: We used panel data from four waves of Shanghai's Longitudinal Survey of Elderly Life and Opinion (1998, 2003, 2005, and 2008). Respondents included 9,680 registered residents in Shanghai aged 65 or older. ADL was measured as a dichotomous variable based on any reported difficulties in eating, dressing, moving on/off bed, indoor transferring, cleaning face and teeth, toileting, bathing, and moving up/downstairs; likewise, any IADL difficulty with cooking, washing, cleaning house, taking medicine, nailing, managing money, making phone calls, getting out in raining, shopping, or going to the doctor were also recorded. Years were categorical indicators referenced to the baseline wave. Covariates included age, gender, rural/urban residence, marital status, social support, social welfare entitlement, comorbidity, symptoms, depression and cognition impairment. Nested random-effect models were applied for estimation. Results: When covariates were controlled progressively, in comparison with elders in 1998, elders in 2008 had 28-39% lower odds of being ADL disabled ($P<0.01$); elders in 2003, 2005, and 2008 were 20-26%, 27-38%, and 59-64% less likely to be IADL disabled respectively ($P<0.001$ for all). Conclusions: The functional health of Shanghai elders has significantly and consistently improved over the recent decade. ADL and IADL results will be discussed in light of recent trends in developed countries.

## SESSION 565 (PAPER)

## ORGANIZATIONAL STRUCTURE AND POLICY

### EFFECT OF NURSING UNIT MANAGER'S TRANSFORMATIONAL LEADERSHIP STYLE ON WORK ENGAGEMENT THROUGH CORE WORK ENVIRONMENT RESOURCES

M. Simpson, *College of Nursing, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin*

Understanding what factors of the nursing work environment best predict nurses' performance has practical implications for improving nursing home resident quality outcomes. The purpose of this study was to test a model (derived from the Models of Job Demands-Resources, Work engagement, and Transformational Leadership) linking nursing unit manager transformational leadership style to work engagement through core work environment resources. A cross-sectional survey study design was employed. The study sample included 147 nursing staff (RNs, LPNs, CNAs) working in 24 nursing homes in one Midwestern state. Structural equation modeling techniques were used to test the hypothesized model using AMOS 7.0 and model fit indices were used to evaluate the fit of the model. The hypothesized model revealed a good fit. Nursing unit manager's transformational leadership style was shown to influence work engagement in two ways: 1) Direct effect on work engagement (.293) and, 2) Indirect effect on core nurse resources (.121). Total model effects demonstrate 41% of the variance in work engagement is explained transformational leadership style and core work environment resources. The effect of nursing unit manager transformational leadership practices on work engagement is further understood through core work environment resources. This finding has important implications for the development of an innovative approach to improving nursing home residents' quality of care outcomes.

### CLASSIFICATION AND DISTRIBUTION OF SERVICES FOR OLDER ADULTS IN US HOSPITALS OVER TIME

A.I. Arbaje[1], Q. Yu[1], B. Leff[1,2], *1. Medicine, Division of Geriatric Medicine and Gerontology, Johns Hopkins School of Medicine, Baltimore, Maryland, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland*

Background: Older adults admitted to acute care hospitals often require specialized services. The patterns of these services nationwide are not well understood. Objective: Describe trends in the classification and distribution of services in US hospitals relevant to the care of older adults. Data and Methods: Retrospective cohort study, 1999 and 2006 rounds of American Hospital Association Annual Survey of Hospitals, a national database of self-reported hospital characteristics (n= 4,998 and 4,831 hospitals, respectively). Services identified as relevant to older adults: adult day care, assisted living, case management, geriatric medicine, geriatric psychiatry, home health, hospice, intermediate care, long-term care, pain management, palliative care, rehabilitation, retirement housing, and social work. Analysis: exploratory and confirmatory factor analysis. Results: Two factors emerged as important categories of services for older adults: inpatient specialty care (pain management, palliative care, geriatric medicine, hospice, social work, geriatric psychiatry, case management, home health, rehabilitation) and post-acute community care (assisted living, retirement housing, intermediate care, adult day care, long-term care). Conclusion: As the population of older adults increases, it is important to understand patterns of services in US hospitals. This study begins to develop a classification scheme clustered into two factors. An important factor related to post-acute community care, a type of service not traditionally viewed as offered by hospitals. This information may be useful to hospital administrators evaluating new service lines, third-party payers configuring benefits, and policymakers restructuring reimbursement, all with the goal of preparing the US healthcare system to adequately care for an increasing number of older adults.

### A USER-CENTERED DESIGN APPROACH TO THE DEVELOPMENT OF A CLINICAL INFORMATICS SYMPTOM ASSESSMENT TOOL

S. Ahluwalia, R. Leos, J.R. Goebel, K. Lorenz, *Veterans Administration Greater Los Angeles, Los Angeles, California*

Background: Although clinical informatics (CI) solutions in healthcare can facilitate quality improvement, there remain considerable challenges to the development of CI tools for palliative care (PC). Effectively embedding the process of symptom assessment within a CI tool is particularly difficult, due to the subjective nature of both the patient experience and provider response. In order to adequately assess end-user needs, we undertook an effort to understand the clinical context within which the tool would be used from the PC provider perspective. We sought to characterize PC provider perspectives on, and approaches to, the assessment and management of dyspnea, as an exemplar symptom, using the qualitative framework of grounded theory. Methods: Semi-structured in-depth interviews of PC physicians and nurses Results: Three themes emerged: 1) The clinical tradeoff between having a simple symptom tool that reflected actual assessment practices and did not contribute to workload, and using an existing, comprehensive tool validated by research; 2) the reliance on qualitative visual observations to assess the presence and intensity of symptoms, rather than a quantitative standardized rating scale; and 3) the considerable variability among providers in their approaches to documentation of symptom assessment. Conclusions: We have illustrated a qualitative approach to developing a user-centered, CI symptom assessment tool for PC practice that considers both the clinical flow and context in which the tool is used. Such a tool may need to incorporate research-validated symptom assessment instruments modified for use in clinical practice to improve ease of use and simplicity, and to allow for both categorical and free text responses in order to be effective and maximize end-user adoption.

## SESSION 570 (PAPER)

## PATIENT AND FAMILY EDUCATION FOR THE END OF LIFE

### PRACTITIONERS' PERCEIVED USEFULNESS AND ACCEPTABILITY OF A FAMILY BOOKLET ON COMFORT CARE IN DEMENTIA

J.T. van der Steen[1], F. Toscani[2], T. de Graas[1], S. Finetti[2], C.M. Hertogh[1], M. Nakanishi[3], T. Nakashima[3], M. Arcand[4], *1. Department of Nursing home Medicine, and Department of Public and Occupational Health, VU University Medical Center, EMGO Institute for Health and Care Research, Amsterdam, Netherlands, 2. Lino Maestroni Foundation-Palliative Medicine Research Institute, Cremona, Italy, 3. Institute for Health Economics and Policy, Tokyo, Japan, 4. University of Sherbrooke, Sherbrooke, Quebec, Canada*

Families of dementia patients may know little about the course of the dementia and comfort care. Conditional for health care providers educating families is them feeling comfortable with doing so. We evaluated a Canadian family booklet explaining comfort care in dementia in physicians and nurses caring for dementia patients in a Southern and Northern European country. Perceived usefulness and acceptability of the booklet was evaluated in 14 nursing homes in Lombardy, Italy, and 21 in the Netherlands, in 2009. Physicians and nurses received a questionnaire and a translated version adapted to local practice. In 10 Dutch homes, physicians evaluated the original Canadian version in English. Acceptability was assessed as a 15-item scale summing rating of agreement with statements regarding, for example, decision-making support and nurses education. Perceived usefulness was defined as usefulness to proportion of families of dementia patients. A total of 168 evaluations were available for multivariable regression analyses. Evaluations of the translated and English version were similar. The booklet was found useful for the majority of families. Profession (nurses) and country (Netherlands) were independently associated with better acceptability. Usefulness was associated with these characteristics in unadjusted analyses only, explained in part by higher educational needs among Italian respondents. Overall, the booklet was welcomed by practitioners of European countries differing in attitudes towards end-of-life care. The booklet may help empower nurses in providing palliative care for dementia patients and their families. Further work will focus on acceptability to families and integration into a training program to also educate practitioners.

### END-OF-LIFE CARE: AN EDUCATIONAL INITIATIVE IN A CONTINUING CARE COMMUNITY

K. Ondus[1,2], E. O'Toole[1,2], *1. Case Western Reserve University - Western Reserve Geriatric Education Center, Cleveland, Ohio, 2. Metrohealth Medical Center, Cleveland, Ohio*

Objective: In the United States, residential care and assisted living communities have increasingly become sites of death for older adults. Yet, several barriers impede the delivery of optimal end-of-life care in theses settings including: variable education, discomfort with delivering end-of-life care and symptom management, communication difficulties, conflicts with families and providers, time constraints and emotional attachment to residents. Method: A multi-educational intervention consisting of: a four-part series of monthly sessions was presented to all employees regardless of department and position, a 6-hour seminar was held for 25 employees respresentative of all disciplines, and ongoing point-of-care education. Evaluation: Evaluation measures consisted of pre-and post measurements at the time of the intervention and follow-up at 18 months. Measures include knowledge, attitude and change in practice related to end-of-life care. Statistical analyses for the initial educational intervention including a paired samples t-test showed significance ($p<.05$)in increased knowledge by participants at all monthly sessions and the all day seminar. Pre- and post-attitudinal survey indicated a significant change (p<.05)in attitudes related to treatments and decision making at end-of-life. The 18-month follow-up is currently being completed. Conclusion: Curricula such as this one with ongoing education can equip staff with knowledge to relieve suffering and improve the quality of life for the residents and their families who are living or dying with life-threatening illnesses in residential care.

### YOU'RE PART OF THE COMMUNITY : OLDER RURAL CANADIAN PALLIATIVE PATIENTS' TRANSITION EXPERIENCES

W.D. Duggleby[1], K. Penz[2], D. Goodridge[3], B. Leipert[4], P.H. Berry[5], *1. Nursing, University of Alberta, Edmonton, Alberta, Canada, 2. SIAST, Regina, Saskatchewan, Canada, 3. University of Saskatchewan, Saskatoon, Saskatchewan, Canada, 4. University of Western Ontario, London, Ontario, Canada, 5. University of Utah, Salt Lake City, Utah*

Background: Older rural persons who are receiving palliative care experience multiple co-existing transitions that can be distressing such as changes in: a) environment, b) roles and relationships, and c) physical and mental health. These transitions do not occur in a vacuum, but occur in a context that reflects the complexities of end of life care and the nature of rural Canadian life. Purpose: The purpose of this study was to explore the context or conditions under which rural palliative care patients experience transitions. Following a study of the transition experiences of older rural palliative patients, an in-depth thematic analysis was conducted of the context in which transitions occurred. Sample/Setting: Six persons with advanced cancer, 10 family caregivers and 12 rural health care professions from three rural health regions in a western Canadian province were interviewed. Design /Method: Interpretive Description qualitative approach was used. Twenty-seven open-ended individual audio-taped qualitative interviews and four focus group interviews were conducted. All interviews were transcribed verbatim, coded, and analyzed. Results: Emerging themes of the context were: a) isolation, b) fatigue and stress, c) lack of information, d) poor communication with health care providers, and e) lack of accessibility to services. At the same time participants described valuing individuality and community connectedness. The findings provide insight into the lives and values of rural older adults who are receiving palliative care services. They also provide the foundation for strategies to support older rural palliative patients as they experience multiple transitions.

### THE EVALUATION OF THE PREPARED (PREPARING RESIDENTS FOR END-OF-LIFE PLANS AND RESPECTING END-OF-LIFE DECISIONS) STUDY

D. Dosa[1,2], P. Gozalo[1], C. Russell-McGregor[3,4], J. Citko[4], J.M. Teno[1], *1. Medicine, Brown University, Providence, Rhode Island, 2. Providence VA Medical Center, Providence, Rhode Island, 3. California Coalition for Compassionate Care, Sacramento, California, 4. Sutter Health-Sacramento, Sacramento, California*

Background: Hospitalization of nursing home (NH) residents during the last months of life is associated with significant risk to the patient, and increased overall cost to the health care system. The PREPARED project was a 2-year collaboration of four hospital systems and 18 NHs in the Sacramento region designed to increase advance care planning and reduce hospitalizations. Methodology: A member of the PREPARED team (a registered nurse or social worker) was detailed to participating NHs for 6 months to provide a weekly half-day educational curriculum related to improving advance care planning. Both process measures and the rate of hospitalizations were examined prior to and after the intervention by independent auditors. Focus groups and indepth interviews were conducted to identify aids and barriers to the intervention. Results: Overall, there was a trend towards reduced hospitalizations (10.7 per facility per month prior versus 9.3 per facility per month) that did not reach statistical significance (p=0.094; CI=-2.03 to 0.16). Pre-post chart review identified no changes in orders to restrict hospitalization (p=0.55), resuscitation (p=0.188), or hospice use (p=0.55). A total of 189 telephone interviews were conducted with decedent family members revealing no statistically significant changes in perceptions of care. Barriers to the intervention included high NH staff turnover, lack of front office and physician buy in, and significant fear of state regulations. Discussion: An educational intervention to improve advance care planning was not sufficient to overcome the considerable barriers in NHs.

## SESSION 575 (SYMPOSIUM)

### PRACTICE CHANGE FELLOWS: FOSTERING LEADERSHIP TO IMPROVE CARE TO OLDER ADULTS

Chair: *E. Coleman, University of Colorado at Denver, Aurora, Colorado*

The Practice Change Fellows program was established to address the critical shortage of effective leaders or "champions" from medicine, nursing, and social work who have the capacity to develop and implement innovative geriatric programs and service lines that meet the unique needs of older adults. Through participation in this program, Fellows enhance their leadership skills and complete projects aimed at improving care for older adults. The program further recognizes its potential to play a strategic role at the interface between health policy and healthcare practice, given that delivery system reform cannot be successful without the experience, expertise and voice of practice leaders. Opinion leader interviews and longitudinal study of Fellows show positive outcomes on leadership skills and organizational impact. Additionally, Fellows are achieving national recognition for their contributions to the field and their projects have demonstrated meaningful impact on improving the lives of older adults.

### THE COACHING APPROACH FOR PERSON-DIRECTED CARE IN HOME CARE AND NURSING HOMES

S. Dawson, *PHI National, Bronx, New York*

Person-directed care is increasingly part of health reform rhetoric, but lacks specifics. The health care workforce has received modest attention, yet—despite accounting for 70% of the eldercare workforce—direct-care workers are rarely embraced as central to reform. The Coaching Approach model builds upon evidence of change management, adult learner-centered education and leadership development to drive person-directed change throughout an entire home care/long-term care organization. This model creates "cross functional leadership teams" and includes a suite of interventions to change the core organizational operating system— communications, decision-making and leadership. This model is currently being tested by PHI, a national nonprofit, in a range of home care agencies and nursing homes. Quantitative and qualitative assessments suggest improvements in efficiency, satisfaction and retention among staff, and in client satisfaction. PHI is working with foundations, researchers, practice leaders and policy makers to support adoption and to study its impact on care systems.

### SUSTAINABLE SYSTEMS FOR EVIDENCE-BASED COMMUNITY HEALTH PROGRAMMING

N. Whitelaw, *NCOA, Washington, District of Columbia*

Community-based prevention and self-management support are part of health reform rhetoric but there is no organized delivery model for this type of health "care." The Sustainable Systems model engages state/regional aging and public health organizations from eight states to establish permanent systems for efficient diffusion of evidence-based health programs to reach diverse vulnerable elders through community organizations. Under this model, strong partnerships with health care providers, health plans, and diverse public/private organizations build statewide systems for participant engagement, training, implementation fidelity, quality assurance and financing. RE-AIM provides an organizing framework for highly interactive shared learning and tailored onsite consultation. Findings include engaging over 20,000 participants;

emerging regional coordinating /management organizations; statewide diffusion with progress on long-term financing. Outcome studies indicate improvements in health status, communication with providers and reductions in utilization. Success of this model contributed to federal and state policy initiatives, including Communities Putting Prevention to Work.

# SESSION 580 (PAPER)

## CIVIC ENGAGEMENT

### ASSESSING BENEFITS OF VOLUNTEERING AND EDUCATIONAL ACTIVITIES AMONG CAREGIVERS OVER 50

J.C. Greenfield, N. Morrow-Howell, *Brown School of Social Work, Washington University in St. Louis, St. Louis, Missouri*

Outcomes associated with participation in educational activities and volunteering were assessed to increase understanding about the effects of social engagement on older adults. The subpopulation of participants who were caregivers are of particular interest, given the challenges that caregiving poses to social activities outside of the home. Study participants were active in the OASIS Institute, a national organization dedicated to enriching the lives of older adults through education and service. The 5,500 respondents represented OASIS participants across 22 cities; they had a mean age of 71 years, were 80% female, 15% non-White, 13% low-income, and 41% living alone. Approximately 21% (n=975) self-identified as caregivers, with 37% of those providing daily care, and 31% providing care at least once each week. Using OLS and logistic regression, and controlling for demographic differences and clustering by location, caregivers were found to report higher perceived benefits from the educational and volunteer engagement than non-caregivers. Benefits included participants' perceived health improvement, increased social engagement, increased desire to continue learning, and attainment of useful skills and knowledge. Higher benefit scores were found among both class takers and volunteers. Findings suggest that while most older adult participants reported some benefit from volunteer and educational activities, caregivers benefited more. However, among respondents who said they had not participated in the last 6 months, nearly 10% cited caregiving responsibilities as the primary reason for non-participation. Further study is needed to understand how caregiver engagement can be supported and benefits maximized for this vulnerable population.

### DOES VOLUNTEERING HELP PROTECT MENTAL HEALTH WHEN IT REALLY COUNTS?

K.J. Johnson, *Gerontology, University of Massachusetts Boston, Boston, Massachusetts*

The purpose of this study was to investigate whether formal volunteering moderates the negative stress-related outcome of increased depressive symptoms associated with the death of a spouse. Previous studies indicate that volunteering reduces depression among older adults. Volunteering was conceptualized as an activity that helps to maintain social support, and it was expected that volunteering would decrease depressive symptoms among the bereaved. Data from four waves of the Health and Retirement Study (HRS) were used for this research. A sample of 8,203 respondents age 60 and older was observed over three transitional periods: 1998-2000, 2000-2002, and 2002-2004. Analyses were based on 21,369 participant observations of respondents who either remained married or became widowed over the three time periods. Ordinary least squares (OLS) regression was used to estimate the effect of transitioning to widowhood and volunteering on the number of depressive symptoms with additional covariates held constant. Generalized estimated equations (GEE) were used to adjust the standard errors for the parameter estimates to account for the non-independence of observations. The results indicate that participating in community-based volunteer work significantly reduces depressive symptoms (-0.16, $p < .01$). However, the positive impact of volunteering among widows is found only among females. Volunteering moderates the negative effect of the death of a husband on the number of depressive symptoms (-.29, $p < .05$) with additional covariates held constant. These findings add to our understanding of the positive effects of volunteering and suggest that volunteering assists some older adults in maintaining social support during stressful transitions.

### SPILLOVER EFFECTS OF VOLUNTEERING ON FAMILY, FRIENDS AND COMMUNITY

E. Gonzales, N. Morrow-Howell, A.M. McBride, S. McCrary, *George Warren Brown School of Social Work, Washington University in St. Louis, St. Louis, Missouri*

AIM. Research has examined the effects of volunteering on the recipient or the volunteer. However, there may be "spillover effects." The purpose of this study is to examine the perceived effects of older adults volunteering in a high intensity program on their family, friends, and greater community. METHODS. Experience Corps (EC) participants consisted of new volunteers from 18 cities in two waves. Wave one respondents (n=227) were queried in an open-ended item as to perceived effects of their EC participation on their family, friends and greater community. Qualitative categories informed closed-ended item development for wave two respondents (n=208), which are reported here. FINDINGS. Positive effects included bringing additional resources, information and new skills back to the family (86%); reducing concern about the older adult because of their involvement with EC (91%); improving relationships or communication with family and friends (83%); increasing family awareness of social issues (90%); and involving family and friends in volunteering (57%). Perceived negative effects on family included interfering with family plans (5%) or having less time with family (29%).Volunteers also reported that they were more likely to vote in favor of public education (95%), more interested in public education (98%), and more likely to advocate for public education (95%). IMPLICATIONS. Positive spillover effects, and few negative effects, are evidenced among the family, friends, and larger community from older adults volunteering, suggesting this is a productive direction for future inquiry. Creating or enhancing certain program features may influence these outcomes directly.

# SESSION 585 (PAPER)

## FINANCIAL ASPECTS OF ELDER ABUSE

### POLICIES AND GUIDELINES ON DEALING WITH SUSPECTED FINANCIAL ELDER ABUSE IN ENGLAND: A POLICY ANALYSIS PERSPECTIVE

D. Stanley[1], A. Gilbert[2], B.L. Penhale[3], D. Cairns[4], M. Davies[4], E. Notley[4], M.L. Gilhooly[4], *1. School of Health, Community & Education Studies, Northumbria University, Newcastle upon Tyne, United Kingdom, 2. School of Applied Psycho Social Sciences, University of Plymouth, Plymouth, United Kingdom, 3. Centre for Health and Social Care Studies & Service Development, University of Sheffield, Sheffield, United Kingdom, 4. School of Health Sciences & Social Care, Brunel University, London, United Kingdom*

This Presentation Will Report on the Method, Content and Findings of an Analysis of Social Policy Documentation as One of Three Phases of an English Study Examining Decisions Made by Managers and Professionals in Health, Social Care and Banking Relating to Detecting and Preventing Financial Elder Abuse. UK Government Policy Places Lead Responsibility for Co-ordinating Local Multi-Agency Responses to Protect Vulnerable Adults From Abuse With Local Social Services Authorities. Despite a Government Commitment to Introduce Legislation, Currently Safeguarding Adults Boards in England Do Not Enjoy Statutory Status. Origins and Definitions of the Terms 'Vulnerable

Adults' and 'Significant Harm' Will Be Discussed in the Context of Developing Legal Instruments and Practice Guidance. Generally, There Is Limited Adult Safeguarding Material in Existence Which Specifically Relates to Financial Abuse and How It Should Be Dealt With or Prevented, to the Extent that Sometimes Even National Reports Are Silent on the Subject, whilst Much of the Financial Sector's Documentation is Subject to Restricted Insider Access. Commonalities and Differences of Views Amongst Stakeholder Communities (Local Authorities, Health, Financial Sector and Law Enforcement) Will Be Explored, Together with Some Implications of the Role of the Office of the Public Guardian and the Potential Contribution of the Recently Introduced Independent Safeguarding Authority. Whilst the Presentation Will Focus on English Systems, Brief Contextual Reference Will Be Made Where Necessary to the Other Three Jurisdictions Within the UK. The Presentation Will Provide Opportunities for Transnational Debate, Comparison and Learning.

### ELDER FINANCIAL ABUSE: OUTCOMES USING A MULTIDISCIPLINARY TEAM

A.E. Navarro[1], K. Wilber[1], D. Schneider[2], *1. Davis School of Gerontology, University of Southern California, Los Angeles, California, 2. Keck School of Medicine, University of Southern California, Los Angeles, California*

Arriving at a remedy for a victim of financial abuse can be time-consuming and complex, requiring interagency cooperation from a diverse array of professionals. Multidisciplinary teams (MDT) offer a critical approach, yet are lacking empirical evidence. This presentation focuses on several outcomes made possible by a specific type of MDT, referred to as an elder abuse forensic center (the Center). This model is defined as a diverse group of professionals that meet weekly to address difficult elder abuse cases through highly focused, problem-solving collaboration, and referrals to appropriate remedies. These efforts are possible in California due to the MDT legal provisions in place, allowing disciplines to share case information across agencies without violating HIPAA, or other privacy statutes. This was an observational study, using administrative data from the elder abuse forensic center and Adult Protective Services (APS). Our anonymous sample consists of community-dwelling victims, age 65 years or greater, residing in Los Angeles County, California. Subjects are those reported to APS from January 2007 to December 2008. The APS clients referred to the Center during this study period (n=171, "enhanced care") are compared, using propensity score calculations to determine APS case matches ("usual care") not involved with the Center with which to compare outcomes. Covariates included socio-demographic data from APS, the Center; and outcome data from several sources, including APS, Public Guardian, and the District Attorney. Empirical evidence has implications for both policy and practice, related to national replication of elder abuse forensic centers designed to protect older adults.

### FINANCIAL EXPLOITATION OF CARE FACILITY RESIDENTS: MODEL PROTOCOL FOR IDENTIFICATION AND INTERVENTION

I.C. Freeman, A. Helgason, *William Mitchell College of Law, Minneapolis, Minnesota*

This paper introduces a model protocol for care facility staff to recognize and intervene when a resident in their facility may be a victim of financial exploitation. Care providers and advocates have long recognized the effects of this type of exploitation, often perpetrated by family members or trusted others. The resident loses a life's savings; the facility is unpaid for months on end; the resident risks discharge for nonpayment; and public assistance is pressed to pick up the pieces. The model protocol, geared to nursing facilities and assisted living, begins with definitions and strategies for preventing financial exploitation of these vulnerable adults. The core includes: Signs of possible financial exploitation of a resident; Action steps for facility staff…emphasizing early intervention; Communication and documentation; Working with families; and the roles and limitations of public agencies. From 2007-09, the Center coordinated a statewide collaborative of more than 50 organizations and agencies to amend Minnesota's Vulnerable Adult law and data practices laws affecting financial institutions to improve investigations and outcomes. This broad interdisciplinary group known as the Vulnerable Adult Justice Project (VAJP) continues to meet on a monthly basis and provided expert advice throughout the process to develop a protocol that is practical from the perspectives of health care workers, social services, and law enforcement.

## SESSION 590 (SYMPOSIUM)

### LIVING ARRANGEMENT, CARE NEEDS, AND WELL-BEING OF OLDER ADULTS IN CHINA

Chair: *T. Lum, University of Minnesota, St. Paul, Minnesota*
Co-Chair: *B. Wu, University of North Carolina at Greensboro, Greensboro, North Carolina*

China is facing a formidable and growing challenge of population aging. By 2050, China will have the largest elderly population in the world with more than 400 million older people. This symposium will focus on living arrangement, care needs, and well-being of older adults in China. The first paper entitled "Co-residence with aging parents in contemporary China: Attitudes and behaviours." Using matched data from the 2002 Chinese Longitudinal Healthy Longevity Survey and the 2002 Dynamic Family Social Survey, the authors examined factors associated with co-residence between adult children and their aging parents. The second paper entitled "Social care needs and life satisfaction among Chinese childless elderly." Using data from the 2005 Chinese Longitudinal Healthy Longevity Survey, the author examined the association between social care needs and life satisfaction of older adults in China. The last paper entitled "Economic development, social support, and well-being of older people in urban China." Using data from the 2004 Urban Household Survey in China, the authors examined how levels of economic development were associated with living arrangement, social support, health and mental health, and life satisfaction of older adults in urban China. Bei Wu, our discussant, will discuss the implications of these findings on the transitions of care of older adults across the aging continuum in China.

### ECONOMIC DEVELOPMENT, SOCIAL SUPPORT, AND WELL-BEING OF OLDER PEOPLE IN URBAN CHINA

T. Lum[1], Y. Xu[2], X. Zhang[2], *1. University of Minnesota, St. Paul, Minnesota, 2. Beijing Normal University, Beijing, China*

China has achieved a spectacular success in its economic development since it started to reform its centrally-planned economy in 1978. However, economic reform also led to large scale population migration as younger adults left less developed areas to seek jobs in more developed coastal cities, leaving older people behind and weaken their social support system. Using data from the 2004 Urban Household Survey, we studied how economic development affected the living arrangement, social support, and well-being of elderly in urban China. Multivariate analyses, including OLS regression and ordered logit regression, were used. We found that lower levels of economic development were associated with lower social support and poor well-being, but the relationship was not linear: More developed cities had significantly better social support and well-being than less developed cities. However, older people in mid-level developed cities have the lowest well-being.

### CORESIDENCE WITH AGING PARENTS IN CONTEMPORARY CHINA: ATTITUDES AND BEHAVIORS

Z. Zhang[1], D. Gu[2], *1. Michigan State University, East Lansing, Michigan, 2. Portland State University, Portland, Oregon*

Coresidence has been the primary means through which aging parents' material, physical, and emotional needs are met in China. Using the 2002 Chinese Longitudinal Healthy Longevity Survey (parents' questionnaire) and its companion data set- the 2002 Dynamic Family Social Survey (adult children's questionnaire), we created 4,003 matched parent-child pairs to examine the follow questions: 1. How does adult children's SES influence their attitude toward coresidence? 2. How are children's characteristics and parental characteristics associated with coresidence? Our preliminary results show that adult children who are more educated and who own their apartments are less likely to agree with patrilocal residence. Those who own their apartments are also significantly less likely to coreside with their parents. Married sons and those who do not have brothers are more likely to coreside. Adult children are also more likely to coreside with parents who are widowed, older, and who have good relationship with the adult child.

### SOCIAL CARE NEEDS AND LIFE SATISFACTION AMONG CHINESE CHILDLESS ELDERLY

J. Sun*, School of Sociology and Population Studies, Renmin University of China, Beijing, China*

Based on the 2005 wave data from the Chinese Longitudinal Healthy Longevity Survey(CLHLS) conducted in 22 provinces in China(n=16093), The study examines the demographic characteristics, social care needs of the childless elderly aged 65 and above, and explores the effective factors of their life satisfaction. Findings suggest that male, the oldest-old, never married are more easily to be the childless elderly. 30.5% of the childless elderly living alone, 18.5% of them living in institutions. The study also finds the social care will be more necessary for childless elderly because of their poor health and shortage of family care. Multiple regression analyses indicated that the childless elderly are less satisfied with their lives and feel more anxious and lonely than do parents. Gender, marriage, individual education, place of residence, living arrangements, economic security and access to medical services are consistently related to life satisfaction among the childless elderly in China. The study indicates that institutional care should be paid attention and economic security and medical insurance for the old persons without child or with only one child should be strengthened.

## SESSION 595 (SYMPOSIUM)

### NURSING HOME QUALITY INITIATIVES – MEASUREMENT AND EVALUATION

Chair: *A. Muma, Abt Associates Inc., Durham, North Carolina*
Discussant: *T. Moore, Abt Associates Inc., Cambridge, Massachusetts*

The Centers for Medicare & Medicaid Services (CMS) oversees the quality of care in our nation's nursing homes. This session will provide background on some current CMS initiatives in evaluating nursing home quality. These initiatives cover a broad range of topics. The Nursing Home Compare Five-Star Rating System: With over a year of data since its introduction in 2008, we present results on the stability and trends in the ratings and underlying components. Additionally, we provide an analysis on whether the methodology used to generate the five-star ratings for quality measures should account for facilities that serve special populations, such as mental illness and pediatric residents. The Quality Indicator Survey (QIS): CMS designed this survey to improve consistency and accuracy by using a more structured process and focusing on areas within facilities with greater quality concerns. We discuss how survey findings differ between the QIS and the traditional survey process in 15 states where the QIS has been introduced. Nursing Home Residents' Satisfaction With Care: This is an important dimension of quality and we report on our recent environmental scan to describe State initiatives that measure and report nursing home satisfaction. We also discuss implications for federal reporting of these data. Use of Therapists and Physician Extenders in Nursing Homes: We present results from an analysis that examines issues for publicly reporting use of these staff and assesses their relationship to nursing home quality and possible inclusion in the Five-Star Rating system.

### NURSING HOME COMPARE FIVE-STAR QUALITY RATING SYSTEM: THE FIRST 12 MONTHS

C. Williams[1], T. Moore[2], A. Muma[1], M.R. Plotzke[2], A.J. White[1]*, 1. Abt Associates Inc., Durham, North Carolina, 2. Abt Associates Inc., Cambridge, Massachusetts*

In December 2008, the Centers for Medicare & Medicaid Services enhanced its Nursing Home Compare website to include "star" ratings for each US nursing home, measuring multiple dimensions of quality. Now that the ratings have been published for one year, we examined rating stability and longitudinal changes in the underlying components. Nationwide, 81% of facilities had their overall rating change by at most one star during 2009. Stability was high in all rating domains: health inspections (91%), MDS quality measures (79%), and staffing (85%). More facilities improved in their ratings than declined. Facilities with extreme initial ratings (1 or 5 stars) had the most stable ratings. Trends toward higher ratings are due primarily to lower reported prevalence of post-acute pressure ulcers, physical restraints and pain in long-stay residents, as well as slight upward trends in adjusted staffing levels. Further scrutiny is needed to evaluate whether changes reflect true quality improvements.

### QUALITY MEASURES FOR SPECIAL POPULATIONS

M.R. Plotzke[2], A.J. White[1], C. Williams[1], T. Moore[2]*, 1. Abt Associates Inc., Durham, North Carolina, 2. Abt Associates Inc., Cambridge, Massachusetts*

We analyze whether the Nursing Home Compare Five-Star ratings for quality measures (QMs) needs to be adjusted to account for nursing facilities that serve special populations. Specifically, we analyze two subsets of specialized facilities, those focusing on: (1) mental illness and (2) pediatric residents. We identify mental illness from diagnoses such as Alzheimer's/dementia, depression, and schizophrenia found on the Minimum Data Set (MDS) and information on residents' mental status from CMS Form 672. We also use the MDS to measure resident age. We examine the number and characteristics of facilities serving these special populations and analyze how these facilities compare to others on the QMs reported on Nursing Home Compare and their QM rating on the Five-Star Rating. Since the QM rating is based on a facility's performance relative to other facilities, we are particularly interested in the impact of specialized facilities on the overall distribution of ratings.

### USE OF THERAPISTS AND MEDICAL SERVICES STAFF IN NURSING HOMES

A.J. White[1], C. Williams[1], M.R. Plotzke[2], R.M. Bertrand[2]*, 1. Abt Associates Inc., Durham, North Carolina, 2. Abt Associates Inc., Cambridge, Massachusetts*

We investigated the use of therapists and physician extenders in nursing homes. The goals of this research were to develop a methodology for publicly reporting information on use of these staff and to assess whether they should be considered in the Five-Star rating system. CMS OSCAR data were used for these analyses. We analyzed staffing levels for therapists and medical services staff (physicians, physician extenders) and the extent to which these individuals are nursing home employees vs. agency staff. Relatively few nursing homes reported the use of physician extenders and fewer than 5% reported having physicians or physician extenders as regular nursing home employees. The majority of nursing homes also reported that therapists worked as contract staff rather than nursing home employees. Findings have implications for the feasibility of including these staff in a payroll-data based public reporting system, as contract hours are not typically included in payroll data.

### THE QUALITY INDICATOR SURVEY – HOW DO FINDINGS COMPARE TO TRADITIONAL NURSING HOME SURVEYS?

C. Williams, A.J. White*, Abt Associates Inc., Durham, North Carolina*

CMS designed the Quality Indicator Survey (QIS) with several goals in mind, including improving survey consistency and accuracy by using a more structured process and focusing survey resources on areas within facilities with greater quality concerns. This new survey strategy has now been implemented to varying extents in fifteen states. We used survey results (cited deficiencies) from more than 3,000 QIS and 16,000 traditional surveys to examine whether survey findings differ between the two processes. Our primary analyses focused on paired analyses for providers that have had both types of surveys. There is no overall trend towards more or fewer deficiencies being cited by the two types of surveys, but substantial state-to-state variation is observed. For example, in Florida, QIS surveys tend to find fewer deficiencies, while in Kansas, QIS surveys cite more deficiencies. It is clear that these trends are evolving as states gain more experience with the QIS.

### NURSING HOME SATISFACTION: EFFORTS AT PUBLIC REPORTING

T. Moore[2], D.T. Hurd[2], A. Edwards[1], *1. Abt Associates Inc., Durham, North Carolina, 2. Abt Associates Inc., Cambridge, Massachusetts*

The nursing home (NH) resident's satisfaction with, or experience with, care, is recognized as an important dimension of quality, and of quality of life, in particular. Though several states have mandated the collection of nursing home resident and/or family satisfaction surveys and publicly report the results of those surveys (e.g., Maryland, Ohio, Rhode Island), CMS's Nursing Home Compare website does not present nursing home satisfaction data or other information about satisfaction. Results of an environmental scan will be presented that describe various federal, state and other initiatives to measure and to publicly report nursing home consumer satisfaction information. Implications for federal reporting of consumer satisfaction will be discussed.

## SESSION 600 (SYMPOSIUM)

### PHILOSOPHY AND AGING: THE PAST, PRESENT AND FUTURE CONSIDERED

Chair: *S. Wright, Gerontology Program, University of Utah, Salt Lake City, Utah*
Discussant: *A. Achenbaum, University of Houston, Houston, Texas*

The symposium will address a variety of topics through a philosophical lens to examine the human condition in the context of an aging body, aging mind, and aging society. It is proposed that the essence of philosophy – the love of wisdom – and its plethora of archetypes and primary areas (e.g., metaphysics, epistemology, ethics, and social and political philosophy) is still relevant today in as it has been for centuries by seeking understanding and meaning of the aging experience through rational discourse in both the existential and scientific domains. This symposium will illustrate, but not exhaust, the robust properties of a philosophical approach to 1) understanding intergenerational obligations and the importance of "legacy" in the context of an aging society; 2) the dimensions and characteristics for a wisdom of aging in an aging society; 3) the process and effects of the temporal dimension on life course processes and the various concepts of time that influence the aging experience; and 4) to examine the potentiality and consequences of a post aging in the near future which may alter the aging experience entirely and have us consider the prospect of existence beyond the limits we assume construct human "being."

### AGING AS LIVING THROUGH DIFFERENT TIMES

J. Baars, *University for Humanistics, Utrecht, Netherlands*

In a culture where chronological time is over-emphasized because of its instrumental value in the planning and acceleration of activities, it comes as no surprise that aging is mainly measured in terms of chronological time. Its result, chronological age, figures in all kinds of tables and overviews concerning 'the aged' although it is unreliable and rudimentary. Moreover, the focus on 'age' tends to occlude the processes that are decisive in determining the characteristics that are statistically related to 'age'. Against this background of an under-reflected overemphasis of chronological time this paper will explore other ways to experience and understand time. The guiding assumption is that aging is, basically, living over a relatively long time but may gain in meaning and content when it is approached as living in or through different times, instead of reducing the understanding of this process to measuring the length of life since birth.

### EARLY-LATE JUDGMENT CONFLICTS: AN EPISTEMOLOGICAL DILEMMA

P.L. McKee, *philosophy, colorado state university, Fort Collins, Colorado*

Old age retrospective judgments present an epistemological challenge. If at the time of choosing a behavior, I judge it to be morally permissible, and then, in old age retrospect, reverse that judgment, which of these conflicting judgments has stronger epistemological credentials? Such early-late judgment pairs present a dilemma, because each has epistemological merits and demerits that seem to offset those of the other. Drawing on passages in Plato and Aristotle, and on the theory of delayed choice in physics, I articulate a feature of our ordinary conception of the past – its "openness" - that resolves the dilemma. After attending this presentation, participants will be better able to observe early-late conflict pairs in judgment, and better able to coherently describe the epistemological basis of old age reversals of judgment.

### POPULATION AGING AND INTERGENERATIONAL JUSTICE

H. Moody, *AARP, Washington, District of Columbia*

There is considerable anxiety among policy-makers about the consequences of population aging, chiefly because of fears that an aging society costs too much in terms of health and pension expenditures. Such fears about the costs and benefits of public programs have for some time fueled debates around the ethical issues of justice between generations. Environmentalists have approached the topic of justice between generations from a different point of view: for example, emphasizing risks to future generations created by problems such as global warming. Here, it is argued that these two discrete domains of intergenerational justice need to be treated together. A major reason for this unified view is the prospect that population aging, and outright population shrinkage, would help to shrink the "ecological footprint" of humanity, permitting high levels of economic productivity enjoyed by a smaller global population. An aging society, in sum, is indispensable for living within the carrying capacity of planet earth. Contrary arguments about intergenerational justice that lead to pro-natalist policies are rejected in favor of an approach emphasizing population aging as a positive strategy for environmental justice.

### POST-AGING: A PROLEGOMENA TO ANY FUTURE TECHNOLOGIES

S. Wright, K. Felsted, *Gerontology, University of Utah, Salt Lake City, Utah*

This presentation will offer a philosophical examination and critique for understanding the emergent and expanding role of technologies that hold both promise and peril for transforming the aging process in this century. This presentation is for participants who wish consider how a new inflection point in our field - post aging – is emergent and has the potential to affect the epistemology and ethics, the expectations and educational practices for the aging experience in our lifetime. We will review five inflection points leading toward post-aging and discuss the continuum of varied intersects and constructs of technologies, that range from purporting to enhance the "activities of daily living" in older adults to those that propose to extend longevity and make senescence negligible, and ultimately claim to transcend "aging" itself - moving toward a transhumanist domain. It is proposed that we have reached critical mass in both the literature and in technological outcomes, and therefore, we can begin to address the actual and speculative impacts on the aging experience.

## SESSION 605 (POSTER)

## POLICY AND EDUCATIONAL PROGRAM

### THE SIGNIFICANCE OF POLICY AND HISTORICAL TIME IN CREATING POSSIBILITIES AND LIMITATIONS FOR DISABLED PEOPLE TO AGE AS A COUPLE

C. Guerrero*, 1. National Institute for the Study of Ageing and Later Life, Norrköping, Sweden, 2. Linköping University, Linköping, Sweden*

This poster looks at life course and aging from the perspective of aging disabled couples, where both partners have lived a long life with disability. Accounting for the experiences of aging disabled people is one of the new emerging topics in gerontology, since disabled people are now living longer lives and it has become possible to observe the aging experiences of this cohort. Little is known about disabled people's family relations outside the original nuclear family, especially when it comes to couplehood, a chosen relation. The aim of this poster is to elaborate on the significance of historical time – of policies, ideologies and social change, mostly in the context of Sweden – in the ability of disabled people to pursue a "normal life course" and "normal aging" which may include building partner relationships, or aging with a partner disabled like oneself. A life course perspective that acknowledges the limits and possibilities of human agency over time and within the individual's historical context is used as a theoretical frame. A country's policies can make certain relationships possible, and some policies may act as hinders. By shedding light on the aging experiences of a subgroup of the aging population (aging disabled people), the study supports the view that the aging population is far from a homogenous group. Historical changes, which in this case are related to disability politics, can affect the experience of individual aging and the life possibilities of aging disabled couples in living a life like others.

### CUTTING MEDICAID HCBW PROGRAMS TO BALANCE STATE BUDGETS: LOW HANGING FRUIT OR POISON APPLE?

T. Jankowski[1], Y. Li[2]*, 1. Institute of Gerontology, Wayne State University, Detroit, Michigan, 2. Indiana University-Purdue University Indianapolis, Indianapolis, Indiana*

The State of Michigan has been struggling with annual budget deficits for several years, and each year the Governor and Legislature review the budget to identify areas in which expenditures can be cut easily and with the least amount of harm to the state and its people. Medicaid is the largest single category in Michigan's budget, and although large portions of the Medicaid budget support mandatory entitlements, a number of programs under Medicaid are optional, making them recurrent candidates for cuts. One such program is Michigan's Medicaid Long Term Care Home and Community Based Waver program, known as the MI Choice program. This study assesses the total direct and indirect cost of proposed cuts to MI Choice expenditures, taking into account not only the Federal matching dollars that would be lost but also the economic multiplier effect of MI Choice expenditures using the RIMS II model, the tax revenue lost from the workers who provide in-home services, and the additional costs that would result from potential MI Choice clients instead seeking institutional long term care under conventional mandatory Medicaid. We find that direct cuts to MI Choice would result in an indirect net loss of jobs and revenue and an increase in other Medicaid expenditures that negate the justification for such cuts.

### AN EVALUATION OF STATE-INITIATED NURSING HOME TECHNICAL ASSISTANCE PROGRAMS

R.M. Bertrand[1], J.S. Gerteis[1], T. Moore[1], Y. Li[3], D.B. Mukamel[2], W. Spector[4]*, 1. Domestic Health, Abt Associates, Cambridge, Massachusetts, 2. University of California, Irvine, Irvine, California, 3. University of Iowa, Iowa City, Iowa, 4. Agency for Healthcare Reserach and Quality, Rockville, Maryland*

Nursing home (NH) quality is a major concern for patients, their families, and health care regulators and policy makers. Federal and state governments have addressed this concern through initiatives including standardization of resident assessment tools, reforms of the regulatory process, publication of NH quality measures, and Quality Improvement Organizations' national quality improvement (QI) activities. However, a paucity of research exists linking QI programs to resident outcomes. The QI state-initiated technical assistance (TA) programs, providing collaborative consultation and training to NH staff, present a unique opportunity to study this relationship given the natural variation in between-state program implementation. The primary objective of this two-phase study was to explore the structural and process variation across TA programs and to evaluate the impact of key components on resident health outcomes. Fifty states and the District of Columbia were contacted and screened; 17 programs met study criteria and representatives were invited to participate in the Phase I web-based survey. Of the 14 programs in the final sample, six provided only telephone or on-site feedback; eight provided telephone, on-site, and mail-based feedback. In all programs, 100% of NHs requesting TA received it; three programs provided assistance without a specific request. Over fifty percent of programs provided formal on-site training (n=9); conducted medical record reviews (n=8); and/or reviewed facility practices (n=9). One state mandated participation. These and other findings confirm the wide variability in TA program implementation. Implications for the variation in the scope and intensity on health outcomes and policy will be examined and discussed.

### A MODEL PROGRAM FOR EDUCATING MIDDLE SCHOOL SCIENCE EDUCATORS IN AGING

C.R. Green, J. Evans, M. Morden, M. Wells, D. Stinson, L.A. Chadiha*, University of Michigan, Ann Arbor, Michigan*

Purpose: Few middle school science educators are trained to teach aging content in their curriculum. As the population of ethnic and racial elderly persons grows, science educators may be a valuable resource for training younger generations of students in minority aging. This presentation's purpose is to describe the recruitment, development, and implementation of an innovative program, African American Aging Summer Immersion for Science Teachers (AASIST), designed to offer middle school science educators a unique opportunity to learn about minority aging and health disparities. Methods: Science educators from greater Detroit were recruited for a 1-year professional development experience focused on minority aging. Program curriculum provided participants with aging knowledge, with a specific focus on African American aging. Fellows attend two GSA annual meetings, participate in an 8-week training module where they learn special topics in aging (bio-medical, behavioral, and social) and design a curriculum module on minority aging for their students. Results: Four inaugural science educators were recruited and participated in the AASIST orientation program and attended the 2009 GSA. Program evaluations revealed the fellows have significantly increased their knowledge about minority aging research, outreach, and policy. Implications: A cadre of science educators who recognize the centrality of minority aging to high quality science is essential. Introducing a cohort of science educators to cutting-edge knowledge about minority aging, research, and practice through the novel AASIST program has significant policy and practice implications by creating additional pipelines for disseminating minority aging to students, science educators, and the community.

### REQUIREMENTS IMPOSED BY IRBS TO RESEARCH INVOLVING DECISIONALLY INCAPACITATED OLDER ADULTS

G. Bravo[1], M. Dubois[1], S. Wildeman[2], J.E. Graham[2], C. Cohen[3], K. Painter[1], S. Bellemare[1], *1. Research Centre on Aging, University Of Sherbrooke, Sherbrooke, Quebec, Canada, 2. Dalhousie University, Halifax, Nova Scotia, Canada, 3. University Of Toronto, Toronto, Ontario, Canada*

Older adults who are solicited for dementia research but who are unable to give direct consent to participation are vulnerable. Existing regulations and guidelines provide little directions to Institutional Review Boards (IRBs) about how best to protect this population. Objectives: To investigate the practices of IRBs regarding research protocols that may involve such individuals and explore the opinions of IRB Chairs on related issues, including longitudinal studies and research advance directives. Methods: Semi-structured telephone interviews with 46 Chairs from 4 Canadian provinces. Results: All IRBs that had reviewed protocols involving decisionally incapacitated older adults allowed these subjects to be enrolled, under certain conditions. Requirements imposed on researchers included seeking subjects' assent where possible, in addition to third-party consent (80%), identifying those responsible for assessing subjects' decisional capacity (60%), and describing the criteria on which determination of capacity would be based (60%). Among the 21 IRBs that had reviewed protocols for longitudinal studies involving older adults at risk of losing capacity, 15 reported requiring researchers to revisit consent at least annually and obtain consent from a legally authorized representative for subjects found to be incapacitated. Most Chairs supported a role for research advance directives in enrolling a person who is incapable of consenting or in retaining a participant who has become incapacitated. Conclusion: We observed significant variability in the oversight activities of IRBs that review protocols involving decisionally incapacitated older adults. We conclude that clearer and more comprehensive regulatory criteria are required for involving this population in research.

## SESSION 610 (SYMPOSIUM)

### PROMOTING HEALTHY URBAN AGING: IDENTIFYING HEALTH RISKS AND INTERVENTION OPPORTUNITIES IN NEIGHBORHOOD SENIOR CENTERS

Chair: *N. Giunta, Brookdale Center for Healthy Aging & Longevity, New York, New York, Hunter College School of Social Work, New York, New York*
Co-Chair: *W. Gallo, Brookdale Center for Healthy Aging & Longevity, New York, New York*
Discussant: *J. Berman, New York City Department for the Aging, New York, New York*

Innovative community-based models are urgently needed to target effective risk prevention and health promotion among urban older adults. The Brookdale Demonstration Initiative in Healthy Urban Aging is a three-year project to contribute to evidence-based program and policy development led by in New York City's Department for the Aging. In Years One and Two, a comprehensive survey was developed and conducted with a representative sample of older adults (n = 1,870) from a stratified sample of 56 senior centers citywide. In-person interviews were conducted in five languages using standardized individual and neighborhood-level instruments. Descriptive data identify targeted areas for program implementation to reduce health disparities. In addition, using an ecological public health approach, determinants of health risks are predicted using multilevel models. In Year Three, the project introduced and assessed targeted evidence-based interventions addressing diabetes and depression among ethnically and racially diverse senior center participants. This symposium will demonstrate The Brookdale Center for Healthy Aging & Longevity's translational approach to inform research, practice, and policy. A multidisciplinary panel will (a) discuss empirical findings from the survey identifying structural and individual predictors of depression and diabetes, and (b) describe the process of implementing two evidence-based programs in senior centers: the IMPACT model of depression care and the DSMP. We incorporate a "research to practice to policy" framework, and encourage discussion from the audience. This pioneering public private partnership provides a rigorous methodological approach to designing and implementing evidence-based interventions for healthy urban aging and risk prevention.

### RESEARCH TO PRACTICE TO POLICY: ECONOMIC BENEFITS OF BRIDGING AGING SERVICES WITH PUBLIC HEALTH

M.C. Fahs[1,2], W. Gallo[1,2], N. Parikh[1], D. Friedman[1], L. Evans[1], M. Ruiz[1], M. Caron[1], *1. Brookdale Center for Healthy Aging & Longevity, New York, New York, 2. Hunter College School of Public Health, New York, New York*

In this presentation, we analyze prevalence rates for the NYC senior center population by ethnicity, for the CDC top seven preventable chronic conditions among older adults. Estimates of large economic benefits of evidence-based interventions are derived. For instance, the NYC senior center population experiences 6,000 falls per year, with 50% requiring medical attention. Using published results from the Medical Expenditures Panel Survey and effect sizes for fall prevention interventions from a comprehensive analysis of literature, we predict a decrease in the fall rate by 30-44% (outcomes established in the literature) will increase quality of life and save $18-26 million in fall-related health expenditures. In addition to public health impact analyses, we developed a Brookdale evidence-based toolkit, as a practical guide for innovative practice development in senior centers. These translational activities, following original research, can help inform decisions by policy makers and program managers facing severe economic constraints.

### EXPLORING A PREDICTIVE MODEL FOR ELDERLY DEPRESSION

W.D. Cabin[1], M.C. Fahs[1,2], W. Gallo[1,2], N. Parikh[1], *1. Brookdale Center for Healthy Aging & Longevity, New York, New York, 2. Hunter College City University of New York, New York, New York*

This paper presents the results of an initial exploration into the interrelationship between neighborhood and individual-level variables and elderly depression. Using data from the Brookdale Demonstration Initiative, a stepwise linear regression was conducted to determine predictors of depression (measured by the PHQ-9). The following eight variables emerged as significant (r-square = .18): low neighborhood satisfaction; little leisure-time physical activity; lower income; visual impairment; hearing impairment; frequent falling; arthritis/rheumatoid arthritis; and presence of a physical disability. These potential predictors of depression require more attention in designing interventions to reduce the risk of depression and improve quality of life among the growing older adult population. The findings suggest the need to design evidence-based models of community-based care to cost-effectively provide early identification, treatment, and management of depression or other chronic conditions which increase the risk of depression among older adults. Limitations and implications for policy, practice, and research will be discussed.

### IDENTIFYING AND ADDRESSING HEALTH RISKS IN SENIOR CENTERS: THE BROOKDALE DEMONSTRATION INITIATIVE (BDI)

C. Morano[1,2], N. Giunta[1,2], N. Parikh[1], D. Friedman[1], M. Caron[1], A. Valencia[1], M.C. Fahs[1,3], *1. Brookdale Center for Healthy Aging & Longevity, New York, New York, 2. School of Social Work, Hunter College, New York, New York, 3. Hunter College School of Public Health, New York, New York*

The purpose of this paper is twofold: (a) describe how BDI survey data were used to identify health risks, specifically depression, to inform a targeted implementation of evidence-based intervention among a diverse population of urban elders; and (b) describe the process of adapting and implementing an evidence-based depression intervention (IMPACT) with Latino and white elders (N=30). The BDI study found that approximately one in four of all BDI respondents (24.9%) exhibited mild to moderate depression symptoms and the prevalence of mild to moderate depression in Latino elders was greater than 30% (32%). This session will focus on the implementation strategy that required a parallel process of training center staff to identify those who might benefit from early intervention and training mental health providers trained in traditional long-term therapeutic approaches. The session concludes with a discussion of the challenges and opportunities associated with implementing evidence-based models of care in community-based settings.

### LINKING AGING AND MEDICAL SERVICE PROVIDERS: UNDERSTANDING BARRIERS IN DIABETES MANAGEMENT AMONG OLDER LATINOS

N. Parikh[2,1], A. Valencia[2], M. Ruiz[2], D. Friedman[2], M. Caron[2,1], M.C. Fahs[2,1], *1. Hunter College City University of New York, New York, New York, 2. Brookdale Center for Healthy Aging & Longevity, New York, New York*

Diabetes is the sixth leading cause of death by disease in the U.S., contributing to increased rates of morbidity, including heart disease, blindness, kidney failure, and other chronic conditions. Results from the Brookdale Demonstration Initiative found that about one in five senior center attendees (21.7%) had diabetes with significant racial/ethnic differences. For example, Latinos compared with non-Latino whites were more likely to report having diabetes (26.5% vs. 14.2%; $p < 0.001$). An evidence-based diabetes intervention, the Diabetes Self-Management Program (DSMP) was implemented to improve self-management activities and behaviors among Latino participants living with diabetes. This paper describes a mixed method approach to better understand linkages between the aging network and the health care delivery system. Cultural (language), social (friends and family networks) and personal (self-efficacy) factors were identified as either facilitating or impeding diabetes self-management strategies. Implications for future research and practice will be discussed.

## SESSION 615 (SYMPOSIUM)

### THE FISCAL CRISIS OF THE STATE AND THE POLITICS OF AGING

Chair: *L. Polivka, The Claude Pepper Foundation, Inc., Tallahassee, Florida*

Politics in the U.S. have become increasingly fractured since the 2008 elections with the emergence of a hyper conservative movement on the right and disillusioned liberals on the left. This fracturing has made it difficult for President Obama and party leaders to generate majorities needed to pass a range of important policy issues from health care to climate change and management of the economy. Support for legislation has been further eroded by the spreading perception that large budget deficits caused by tax cuts, rising military expenditures, and the 2008-10 recession are potentially greater threats to the nation's economic future than low consumer spending, the housing crisis and a greatly weakened financial sector. These perceived threats have fueled renewed efforts to contain federal spending and raised questions about whether or not the politics of policies on aging and the federal budget deficit will lead to a dismantling of the U.S. old age welfare state that was constructed in the 20th century. The panel will address these perceived threats through an analysis of voting and public opinion polling results and a critique of the neoliberal economic model that continues to limit political choices and economic policy options.

### THE POLITICS OF AGING : PRE- AND POST- THE 2010 ELECTION

R. Binstock, *Case Western Reserve University, Cleveland, Ohio*

During the health reform saga of 2009 an overarching message of President Obama from the outset was that the costs of health reform would be offset through savings and cutbacks in Medicare, such as reducing the subsidies to Medicare Advantage plans. During the summer, fears among seniors about Medicare cuts were amplified at town meetings where the specters of "death panels" and "pulling the plug on granny" were added to the mix. Early in 2010, the Senate, the Chairman of the Federal Reserve, and President Obama zeroed in on controlling spending on entitlements (read Social Security and Medicare) as the pathway to reduced and responsible federal deficits. Did all this have an observable impact on older voters in the 2010 election? Will the politics of policies on aging in 2011 lead to a dismantling of the U.S. old-age welfare state that was constructed in the 20th century?

### PUBLIC SUPPORT FOR PROGRAMS FOR OLDER AMERICANS IN DIFFICULT TIMES: CONTINUITY AND CHANGE

F.L. Cook, *Institute for Policy Research, Northwestern University, Evanston, Illinois*

Although support for programs for older Americans has traditionally been high, the debate in 2009-10 over the Obama Administration's health care reform proposals revealed deep fractures in views about the role of government in protecting citizens. Partisan politics reached new highs of fractiousness. The purpose of this paper is to step back and assess what the public's views of Medicare and Social Security are and the level of confidence that the public has in the future viability of these programs. We find that support continues to be strong but that the public is very concerned about the future of these programs. We conclude by discussing the importance of the public's lack of confidence in the financial strength of Social Security and Medicare and what it might mean for the public's support for the programs.

### THE POLITICAL ECONOMY OF GROWTH AND THE POLITICS OF AGING AND SECURITY

L. Polivka, *The Claude Pepper Foundation, Inc., Tallahassee, Florida*

Retirement benefits for the elderly depend on the kind of equitable economic growth that characterized the U.S. economy from the end of World War III until the late 1970's. With the election of Ronald Reagan in 1980 the equitable growth model of managed capitalism rapidly gave way to a conservative model of the political economy (neoliberalism) designed to reduce the role of government in the economy and curtail the welfare state through deregulation of finance and other facets of the economy, tax cuts on higher income earners, privatization of public sector services, and reductions in funding for social programs. The neoliberal model has generated relatively slow economic growth and the deepest recession since the Depression. This presentation will include a description of the kind of alternative economic model the U.S. needs to restore equitable growth and security for future retirees.

## SESSION 620 (SYMPOSIUM)

### THINKING CRITICALLY ABOUT INTERDISCIPLINARY TEAMWORK IN GERIATRICS: PAST, PRESENT, AND FUTURE

Chair: *P. Clark, Gerontology, University of Rhode Island, Kingston, Rhode Island*
Discussant: *C. Langston, The John A. Hartford Foundation, New York, New York*

Recent reports from the Institute of Medicine, as well as professional association recommendations, have highlighted the increasing importance of training current and future health care professionals in interdisciplinary geriatric teamwork. How do we understand the challenge of designing educational programs to address this need? How can lessons of past attempts to develop and continue such efforts be applied to the future? What unique issues confront higher education in addressing this challenge? What types of teamwork models will be needed to meet future needs? These questions, and potential answers to them, are the focus of this symposium. The first paper discusses the history of interdisciplinary teamwork, examines the contributions made by team initiatives, and reviews lessons learned from a variety of programs in the public and private sectors. The second paper develops a typology of potential barriers to designing effective programs in higher educational settings and integrates these into a conceptual framework suggesting potential ways of addressing them. The third paper develops an analytical framework based on teamwork structures and processes to analyze different types of geriatric teams in differing settings. The final paper summarizes lessons from a recent initiative in Canada to build capacity in frailty-focused care within primary care teams. These include the use of network theory and analysis to inform team development, and the application of team constructs to diverse types of health care organizations. Implications and recommendations for developing, implementing, and sustaining interdisciplinary geriatric teamwork education and practice to meet future health care needs will be developed.

### INTERDISCIPLINARY TEAMWORK: LESSONS HISTORY CAN TEACH US FOR THE FUTURE

R. Tsukuda, *Portland VA Medical Center, Portland, Oregon*

With over 40 years of effort devoted to promoting interdisciplinary teamwork in health care settings, why do we continue to ask the same questions? There is a rich body of literature discussing health care teams. Despite this, issues of team productivity, effectiveness, outcomes, process, and barriers remain focal points for inquiry. At the same time, we continue to advocate for teams to exist and promote them as the “best” way to deliver care. This paper will discuss the history of interdisciplinary teams, examine the contributions made by team initiatives, and review lessons learned from a variety of programs in the public and private sectors. Learning from the past, implications for the future of interdisciplinary practice and education in a volatile health care environment will be discussed.

### PERILS, PITFALLS, AND PROBLEMS OF INTERDISCIPLINARY TEAM TRAINING PROGRAMS IN HIGHER EDUCATION

P. Clark, *Gerontology, University of Rhode Island, Kingston, Rhode Island*

Higher education presents unique challenges for the development, implementation, and continuation of interdisciplinary geriatrics team training programs. In spite of recent calls for the expansion of such programs, significant barriers remain to their long-term success. This paper develops a typology of such factors and integrates them into a conceptual framework suggesting some potential solutions. Barriers and facilitators are conceptualized within the following categories: (1) high-level administrative support without appreciation of resources necessary for success, (2) low-level administrative support with high faculty involvement, (3) external pressures created by training grants, and (4) external forces such as certification, licensure, and accreditation. Implications for the successful continuation of programs include: (1) the importance of a strong administrative, faculty, and resource foundation, (2) the presence of champions or advocates for interdisciplinary training, (3) pressures applied by accrediting and licensure bodies, and (4) the need for a strong theoretical and research base for the field.

### TEAM STRUCTURES AND PROCESSES AS TEAMWORK DOMAINS: IMPLICATIONS FOR EDUCATION AND PRACTICE

K. Hyer, *University of South Florida, Tampa, Florida*

Interdisciplinary care models evolved from VA geriatric inpatient assessment teams that began in the 1970s to review multiple domains for comprehensive assessment. While “interdisciplinary team care” is espoused as the standard for geriatric patients, teamwork structures and processes vary by setting. Hartford’s Geriatric Interdisciplinary Team Training (GITT) program identified team structure and process as key elements of team training. Using structure (purpose of team, physical proximity of members, size and composition of team, and role of patient) and team process (communication processes, frequency and regularity of team meeting, establishment of meeting goals and objectives, and audit of team outcomes) as teamwork domains, this presentation compares and contrasts: (1) geriatric assessment teams, (2) primary care teams in managed care, and (3) Program for All-Inclusive Care for Elderly teams caring for complex, long-term care patients in different settings. Implications for developing models and methods of interdisciplinary education and teamwork practice are explored.

### GERIATRICS, INTERPROFESSIONAL PRACTICE AND INTERORGANIZATIONAL COLLABORATION: LESSONS FROM PRIMARY CARE TEAMS

D.P. Ryan[1,2], B. Liu[1,2], W. Dalziel[7], C. Cott[2], D. Jewel[3], M. Kelley[6], J. Puxty[5], I. Gutmanis[4], *1. Regional Geriatric Program of Toronto, Toronto, Ontario, Canada, 2. University of Toronto, Toronto, Ontario, Canada, 3. McMaster University, Hamilton, Ontario, Canada, 4. University of Western Ontario, London, Ontario, Canada, 5. Queens University, Kingston, Ontario, Canada, 6. Lakehead University, Thunder Bay, Ontario, Canada, 7. Regional Geriatric Program of Eastern Ontario, Ottawa, Ontario, Canada*

Compelled by population aging and chronic disease, federal and provincial governments in Canada have designed strategies to develop interprofessional training and practice. In Ontario, family health teams are part of these strategies, and a province-wide initiative to build capacity for geriatric care within these teams reveals important teamwork issues. Health professionals continue to have scant preparation in geriatrics, and while interprofessional education is growing, transfer into practice remains challenging. Training continues to be largely hospital-based, while the structure of community teamwork may be unique and dependent on skills—inter-organizational teamwork—not presently in curricula. Team metrics blended with network theory and analysis add value in the community context, and edumetric approaches to measurement informs both research and practice. Finally, the team construct continues to be applied to diverse health care organizations and the idea of teams as emergent individualized practice networks is an important new theme to inform team theory.

## SESSION 625 (SYMPOSIUM)

### AGE TRANSITIONS IN SOCIAL RELATIONS: AN INTERNATIONAL PERSPECTIVE

Chair: *K.J. Ajrouch, Eastern Michigan University, Ypsilanti, Michigan*
Co-Chair: *M. Broese Van Groenou, VU University, Amsterdam, Netherlands*

This symposium capitalizes on detailed social relations measures available in five diverse parts of the world: The Netherlands, Eastern Europe, China, Mexico, and the U.S. We investigate whether socio-demographic and health factors influence social relations across the life course similarly or differently within each country. Broese van Groenou and colleagues address the issue in The Netherlands. Using multilevel models, they find that cognitive functioning was most strongly associated with network changes, but health indicators did not fully explain the effects of age and time. de Jong Gierveld disentangles cultural, socio-economic, and health predictors of co-residence in Eastern Europe to find that cultural values explain co-residence to a certain extent, but socio-economic norms and needs of the younger and middle generation also influence the likelihood of co-residence. Cong and Silverstein address changes in support networks of grandparents who care for grandchildren in rural China. They find that changes in support exchanges are most aptly detected within spousal relations, not parent-adult child relations. Fuller-Iglesias examines age differences in social relations using data from Mexico. Multi-level regression analyses demonstrate that age differences in social relations are mediated by education level and health status. Finally, Webster and Antonucci examine transitions in social relations among adults 50+ in the U.S. Findings suggest changes in health status predict changes in the frequency with which adults have contact with key network members. In sum, a systematic examination of age transitions in social relations across various national contexts provides an international perspective and distinctive insights into growing older.

### CO-RESIDENCE IN GEORGIA: OLDER AND YOUNGER ADULTS' PERSPECTIVES

J. Gierveld, *NIDI, Den Haag, Netherlands*

Support relationships between older and younger generations differ between countries. In some regions support is predominantly organised via co-residence of older people and their adult children, based on a cultural context of interdependent family lives. In this paper the theoretical ideas of Reher, of Adams c.s. and others are investigated, to disentangle cultural, socio-demographic, socio-economic and health predictors of co-residence. Data come from the Generations and Gender Survey of Georgia (N=10.000; age 18-79 years).Taking the perspective of the older and the younger generations, respectively, a nuanced outcome is shown. Cultural values do explain co-residence to a certain extent, but additionally socio-economic norms and needs of the younger and middle generation were associated with the prevalence of supportive relationships; resulting in decreasing risks of co- residence situations.

### LOSING AND GAINING PERSONAL RELATIONSHIPS IN LATER LIFE: THE EFFECTS OF HEALTH

M. Broese Van Groenou, E. Hoogendijk, T. Van Tilburg, *Sociology, VU University, Amsterdam, Netherlands*

The study examined changes in network size by distinguishing between continued and new relationships and studying the effects of physical and mental health. The Longitudinal Aging Study Amsterdam interviewed older adults up to seven times over a time period of 17 years (N = 2819). The number of continued and new relationships were calculated between the waves. Results from multilevel analyses showed significant effects of age, time, age * time and health. Continued relationships decreased and new relationships increased over time, but less so at higher age. Cognitive functioning was most strongly associated with network changes, but the health indicators did not fully explain the effects of age and time. It is concluded that a decrease in network size in old age is the result of reduced replacement of lost network members. Health plays an important role, but other explanations must also be investigated.

### AGE DIFFERENCES IN SOCIAL RELATIONS IN MEXICO: GENERATIONAL OR TRANSITIONAL EFFECTS?

H. Fuller-Iglesias[1], T. Antonucci[2], *1. Human Development and Family Science, North Dakota State University, Fargo, North Dakota, 2. University of Michigan, Ann Arbor, Michigan*

Cross-cultural studies have identified differences in how social relations change over the life course; however, little is known about trends in Mexico. Though age differences in social relations have been documented in Mexican samples, it is unclear whether these differences reflect age transitions or generational differences. Using data from the Survey of Social Relations and Well-being in Mexico (Fuller-Iglesias & Antonucci, 2009), this study examines whether education and health have a mediating effect on age differences in social network structure and support quality in Mexican adults aged 30-99 (N=933). Multi-level regression analyses indicate that age differences in network size and family makeup of network were mediated by education level. Age differences in frequency of contact were mediated by health status. Moreover, further analyses suggest mediating effects of education level for age differences in support quality. Findings and implications will be discussed within the context of generational and transitional effects.

### CHANGES IN THE SUPPORT NETWORKS OF GRANDPARENTS WHO CARE FOR THEIR GRANDCHILDREN IN RURAL CHINA

Z. Cong[1], M. Silverstein[2], *1. Human Development and Family Studies, Texas Tech University, Lubbock, Texas, 2. University of Southern California, Los Angeles, California*

Elders in rural China often take custody of their grandchildren when their adult children migrate to urban areas for employment. This study examined how elders' support network size (number of people) and volume (frequency) changed when grandchild-care was initiated. Using data from 1,640 elders from a four-wave longitudinal study (2001-2009) in Anhui Province, China, we used robust regression on 4,000 person-intervals and found that caring for grandchildren reduced the number of people from whom they received instrumental support, reduced the volume of support received from children, but increased support from spouses. Caring for grandchildren increased the number of people to whom elders offered help. In terms of volume, elders provided less support to children and more to their spouses. Providing and receiving support from siblings, friends and neighbors were not influenced. Our findings suggest that realignment in support networks initiated by the care for grandchildren remains primarily in the stem-family.

### WHO'S THERE TO CARE? SOCIAL NETWORKS, AGING AND HEALTH TRANSITIONS IN THE U.S

N.J. Webster, T. Antonucci, *Life Course Development Program, Institute for Social Research, University of Michigan, Ann Arbor, Michigan*

This study examines how longitudinal changes in the number of chronic illnesses are related to later life structure and composition of social networks. Data come from two waves (1992; 2005) of the Social Relations, Aging and Health Study, a regionally representative sample of the Detroit Metropolitan area. Respondents age 50 and older at wave 2 were selected (N=543) for analysis. Regression analyses reveal that respondents who reported an increase in the number chronic illnesses had networks comprised of a greater proportion of family and had less frequent contact with network members at wave 2. Findings highlight the distinction in the U.S. between family and friends. Family relationships are often considered obligatory and include expectations to meet demands (i.e., caregiving), an aspect evermore apparent in the context of later life health transitions. Sick older adults' less frequent contact with networks suggests more needs to be done to help them stay connected.

## SESSION 630 (SYMPOSIUM)

### AGING AND THE LIFESPAN: THE ROLE OF HEALTH IN TIME AND CONTEXT

Chair: *N. Ram, Department of Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania*
Co-Chair: *D. Gerstorf, Department of Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania*
Discussant: *M. Sliwinski, Department of Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania*

Health holds a prominent role in how individuals' lives progress – day-to-day and decade-to-decade. In this symposium, we highlight work that targets health at multiple time scales and in multiple contexts and consider explicitly the interplay between theory and methods. D. Gerstorf and N. Ram illustrate the potential and limits of long-term panel data in their examination of mortality-related health processes in late-life development, and how between-person disparities in those processes are shaped by individual and macro-contextual factors, including disability, living environment, and historical time. S. Zarit and colleagues illustrate the utility of controlled interventions and intensive observation in their study of the immediate and discrete effects of treatment on health-related effects of exposure to and appraisals of stress among caregivers. Almeida and colleagues demonstrate the usefulness of diary methods in their evaluation of the dynamic interplay between day-to-day psychological stress and hormonal reactivity and how such chronic stress processes may contribute to an increased risk of illness and mortality. L. Martire and colleagues illustrate how micro-longitudinal assessments can be used to understand the associations among health behaviors (daily physical activity) and well-being measures (pain, negative mood, and positive mood), and how those associations progress along different time intervals. M. Sliwinski integrates the four empirical papers and discusses how the various types of longitudinal research contribute to further understanding of the role of health for adult development and aging.

### THE MULTIDIMENSIONAL NATURE OF LATE-LIFE DECLINE: INSIGHTS OBTAINED THROUGH THE INTERPLAY OF THEORY AND METHODS

D. Gerstorf, N. Ram, *Department of Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania*

Lifespan research focuses on how and why individuals, as multidimensional entities, grow and decline. We illustrate how the alignment between longitudinal methods and research hypotheses is targeting and prompting further refinement of long-standing questions about late-life physical and mental health. Specifically, using data from multiple longitudinal studies we highlight how (1) alternative time metrics are being used to test whether late-life development is primarily driven by age-related or mortality-related processes; (2) explicit modeling of multiple phases of development provide for more refined evaluation of between-person differences in onset and progression of physical and mental health declines; and (3) incorporation of individual and macro-contextual factors, including disability, living environment, and historical time allows for identification of the possible antecedents and correlates of between-person disparities in late-life change. We conclude by outlining how integrated multivariate inquiries may provide for an additional set of insights into the complex dynamics of late-life health.

### REPEATED DAILY ASSESSMENTS AS AN EVALUATION STRATEGY: THE CASE OF ADULT DAY CARE

S.H. Zarit, K. Kim, E. Femia, L.C. Klein, D. Almeida, *Human Development & Family Studies, Penn State University, University Park, Pennsylvania*

Clinical interventions have long used repeated daily observations for guiding and evaluating treatment. Daily observations provide immediate evidence of the effectiveness of treatment components and can be integrated into a within person, A-B-A-B design, in which treatment is alternately administered and withdrawn. This approach is particularly promising for evaluation of adult day care and similar services for family caregivers, where randomized trials are not usually feasible. We present findings from two studies of adult day care that compare exposure to stressors for caregivers of people with dementia across multiple days on which their relative either uses or does not use day care. Exposure to care-related stressors and stress appraisals are greatly reduced without commensurate increases in non-care related stressors, with implications for immediate and longer-term outcomes. These results suggest that daily observations may be useful for identifying the effects of intermittent interventions such as adult day care.

### DAILY STRESSORS AND DIURNAL CORTISOL: TOWARD A DYNAMIC VIEW OF ALLOSTATIC LOAD

D. Almeida[1], R.S. Stawski[1], J.R. Piazza[1], K.E. Cichy[2], *1. Penn State University, Univeristy Park, Pennsylvania, 2. Kent State Univerisity, Kent, Ohio*

Current stress theories suggest that chronic exposure to hormones elicited by stressors leads to accumulated wear and tear on the body, referred to as allostatic load. In this paper we use diary methods that obtain repeated measurements from individuals during their daily lives to assess associations between real-life stressors and salivary cortisol in the National Study of Daily Experiences. Respondents completed nightly interviews about daily stressors at two time points across a 10 year period. The analyses differentiated between individuals who were high at both occasions versus low at both occasions in stressor exposure and reactivity. The results showed that individuals who were high in their stressor exposure at both time points had dysregulated cortisol rhythms. Compared to their younger counterparts, chronically stressed older adults showed the greatest amount of cortisol dysregulation. Discussion will focus on how daily stress processes may contribute to an increased risk of illness and mortality.

### DAILY PHYSICAL ACTIVITY AND CHANGE IN PAIN AND MOOD OVER DIFFERENT TIME INTERVALS

L. Martire[1], M.P. Stephens[2], J. Brach[3], F. Keefe[4], R. Schulz[3], *1. Penn State University, State College, Pennsylvania, 2. Kent State University, Kent, Ohio, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, 4. Duke University, Raleigh, North Carolina*

Exercise programs for older adults are successful in reducing joint pain, enhancing function, and maintaining weight over the long term. However, the short-term effects of daily physical activity are likely to be more complex. More activity may exacerbate pain on the same day but lead to decreased pain on the next day or across several days. In addition, daily physical activity may benefit mood but little is known about the time frame for this effect. We will use data from a dyadic study of older adults with knee osteoarthritis and their spouses to explore these research questions. In this study. participants used an electronic diary to provide daily data for 21 days regarding mood and patient pain, and wore an accelerometer to measure daytime physical activity over the same 21 days. Presented findings will focus on associations among daily activity, pain, negative mood, and positive mood across different time intervals.

## SESSION 635 (POSTER)

## ATTITUDES TOWARD AGING AND OLDER ADULTS

### ADOLESCENTS' ATTITUDES TOWARD WORKING WITH OLDER ADULTS: STUDENTS WHO STUDIED THE HELPING PROFESSION COURSES IN TEXAS HIGH SCHOOLS

S. Lin[1], J. Scott[2], K.L. Alexander[2], *1. Applied Science of Living, Chinese Culture University, Taipei, Taiwan, 2. Texas Tech University, Lubbock, Texas*

By year 2040, the older population in Texas will reach 8.1 million, comprising 23% of the total population in the United States (Texas Department of Aging, 2003). Services for older adults, such as home health care and community care for elderly, have been identified as having the highest projected employment growth rates among other occupations in Texas by year 2014 (Texas Workforce Commission, 2008). The purpose of the study was to identify adolescents' attitudes toward working with older adults upon completion of high school. The sample included adolescents between 8th and 12th grade (N = 715) from 20 school districts in Texas who had studied the helping profession courses, including courses from Family and Consumer Sciences and Health Science Career Clusters. They were asked to complete a 69-item questionnaire and the data were analyzed with structural equation modeling (SEM). The results showed that the adolescents' attitudes toward working with older adults were positively influenced by their prior experiences with older adults ($\beta = .22$, $p < .001$) and by their course experiences that included gerontology content ($\beta = .82$, $p < .01$). However, they showed little interest in considering seeking a job specifically focused on older individuals/clients. The findings support continued need for career based curriculum at the high school level which provides experiences with older adults and knowledge of jobs that serve older adults. Future research should focus on identifying the reasons students lack an interest in jobs exclusively focused on older adults.

### HOW DIFFERENT INDICATORS PREDICT GENERAL ATTITUDES TOWARDS AGING AND SELF-PERCEIVED AGING

C.M. Strickland, D. Kotter-Gruehn, *Psychology, North Carolina State University, Raleigh, North Carolina*

Positive attitudes toward aging and optimistic self-perceptions of aging can help individuals adapt to age-related changes throughout the life span and add to longevity and quality of life. This study examined (a) whether one's general attitude towards aging and one's self-perceived aging are predicted by different indicators and (b) whether the predictive pattern differs as a function of age group. A total of 180 young, middle-aged and older adults responded to questionnaires assessing, among others, our predictor variables life satisfaction, future-orientation and age anxiety as well as our outcome variables attitudes towards aging and self-perceived aging. Preliminary results support the notion of concept- and age-group-specific predictors. High anxiety about aging was related to more negative attitudes towards aging in all age groups whereas it predicted self-perceptions of aging only in old age. Positive future-orientation predicted positive self-perceptions of aging in all age groups but was only relevant for general attitudes towards aging in middle-aged adults. Life satisfaction was positively correlated with self-perceptions of aging for middle-aged adults, but for older adults it better predicted general attitudes toward aging. These findings suggest that individuals perceive their own aging differently than aging in general. Furthermore, the identification of age-group specific factors explaining interindividual differences in perceptions of aging can help guide future research.

### BARRIERS TO SYMPTOM MANAGEMENT IN OLDER ADULTS: AGEIST BELIEFS, ATTITUDES, AND COMMUNICATION DIFFICULTIES

H. Yeom, S.M. Heidrich, *School of Nursing, University of Wisconsin-Madison, Madison, Wisconsin*

According to the Common Sense Model, beliefs about a health threat guide health behaviors and these behaviors influence health outcomes. This study investigated three types of belief about symptom management that may act as barriers to better health outcomes in older adults: negative symptom management beliefs (SMBQ), perceived ageism from health care providers (CommA), and difficulties in communicating about symptoms (CommD). They reflect negative aging stereotypes on the part of both older adults and health care providers. The specific aims of this study were to investigate the direct and indirect effects of barriers on quality of life (QOL) and whether communication difficulties mediate the influence of SMBQ and CommA on QOL. A secondary data analysis was conducted using baseline data from a randomized clinical trial testing the effects of an Individualized Representational Intervention (IRIS) in reducing symptom distress and improving QOL in 190 older breast cancer survivors (M age=70.4 yrs). QOL measures included the SF-36 physical and mental scales, purpose in life (PIL), and positive relations with others (PR). Results of path analyses indicated significant direct effects of SMBQ and CommA on CommD (path $\gamma$=.86, p <.01; $\gamma$=.16, p=.011, respectively), after adjusting for age, comorbidities, and number of symptoms. Significant indirect paths from CommA to QOL supported the mediating effects of CommD for SF36-mental ($\gamma\beta$= -.035, p=.05), PIL ($\gamma\beta$ = -.042, p=.041), and PR ($\gamma\beta$= -.044, p=.039). The findings suggest the importance of effective communication with health care providers about symptoms to enhance quality of life in older cancer survivors.

### FOLLOW UP "OLD TALK" FINDINGS: FURTHER EXPLORATION OF THE MOTIVATION OF INTERNALIZED AGEIST SPEECH

A. Stripling, M.(. Heesacker, *Psychology, University of Florida, Gainesville, Florida*

The goal of this investigation was to identify people's motivations for engaging in "old talk," defined as ageist, self-referential statements, regardless of one's chronological age. Flanagan's Critical Incident Technique was employed to examine the old talk of 293 individuals ages 18-80, 58% of whom identified at least one old talk incident, and thus were included in the analysis of motivations. Analysis of participants' self-reported motivations for engaging in old talk revealed seven motivation categories (1) Ipsative (32.4% of the events; e.g., "Because it didn't happen when I was younger."), (2) Instrumental (27.8%; e.g., "As justification for not remembering names"), (3) To Describe Personal Experience (14.1%; e.g., "I was forgetful."), (4) To Compare with Others (7.9%; e.g., "I felt old in comparison to the others"), (5) Self Stereotyping (6.9%; e.g., "'cause old people have back pain"), (6) To State Facts, (3.2%; e.g., "Because it's true!") and (7) To Minimize Aging (0.9%; e.g., "I never refer to being old, just older"). The mean age of participants citing Instrumental motives (M = 47.06, SE = 2.11) was significantly older than the mean age of those reporting other motives (M = 39.97, SE = 1.27; t (205) = 3.024, p = .003). No other age differences in motivations were discovered. Ipsative and instrumental motives together accounted for over 60% of the total motivations provided. These results begin to uncover potential motivations that drive individuals' internalized self-directed ageism and pave the way for experimental and other studies.

### PARTICIPANTS' AND MEDICAL PROFESSIONALS' ATTITUDE TOWARD AND PREFERENCES FOR DISCUSSING AND MAKING DECISIONS ABOUT PHYSICAL FUNCTIONING

R. Beeco[1], J.O. Brooks[1,2], W.C. Logan[3], M. Cress[4], J. Gomer[1],
A.K. DeArment[1], *1. Clemson University, Clemson, South Carolina, 2. Greenville Hospital System University Medical Center, Greenville, South Carolina, 3. Palmetto Health, Columbia, South Carolina, 4. University of Georgia, Athens, Georgia*

Evaluation of older adult's functional status is an essential component of assessing functional independence and decision making for therapeutic modalities. A critical evaluation of seniors' acceptance of performance based testing is lacking. The Continuous-Scale Physical Functioning Performance Test (CS-PFP 10) was administered to 67 seniors (M=69.4, SD=8.0 yrs) with a broad range of functioning. A survey assessing the attitudes and preferences for discussing physical functional performance was also completed by the participants and medical professionals (N=32) familiar with the CS-PFP 10. When asked with whom they preferred to speak regarding their physical functioning, the majority of participants indicated that they would most prefer speaking with and would be most likely to listen to their spouse or doctor, but would also speak with a member of their family (e.g., child), a close friend, or other healthcare professional. The medical professionals reported that the tasks in the CS-PFP 10 provided a useful measure of physical function and were clearly connected to independent living. Of the medical professionals who had spoken with someone about their physical function, nearly all felt having the results of the CS-PFP 10 would have changed the conversation to allow the discussion to revolve around more specific and objective information.

### WHEN I GROW UP: EXAMINING PROJECTED GAINS, MAINTENANCE, AND LOSSES IN AGING ADULTS

G.P. Freeman[1], S.K. Whitbourne[1], G. Westerhof[2], *1. University of Massachusetts Amherst, Amherst, Massachusetts, 2. University of Twente, Enschede, Overijssel, Netherlands*

There has not been much research on the future perspective of aging adults. We therefore used six open-ended sentence completion stems, derived from the SELE questionnaire (Dittmann-Kohli, 1995; Dittman-Kohli & Westerhof, 1999), to examine respondents' projections of possible gains, maintenance, and losses regarding aging and the future. A gain was defined as an event or circumstance the participant characterized as an improvement, a loss defined as deterioration, and maintenance defined as a continuation of the status quo. Respondents were 133 adults (54 male) with ages ranging from 40 to 84 years of age (M = 60.2). With 133 respondents and 6 stems, 798 responses were coded for future perspective. Three-hundred thirty-three responses were coded as a gain (i.e., In the next few years... "I will spend more time on me"), 104 indicated maintenance (i.e., Later when I'm older... "life will be just as enjoyable"), 227 were coded as anticipated losses (I am afraid that I... "will not be there to see my grandchildren grow"), and 134 did not fit into these categories. Further coding separated projections into specific content areas. Examining gains, statements concerning increased enjoyment of life were most common (N = 97, 29.1%). Examining losses, statements of physical decline were most frequent (N = 59, 26.0%). Additionally, other psychological variables were assessed—identity processes, self-esteem, and aging experience. Systematic relations with these variables were found, e.g., self-esteem and projected gains (r = .185, p < .05). This research underscores the benefit of utilizing open-ended and traditional inventories in tandem.

### HUMAN SERVICE PROFESSIONALS INTERACTION WITH THE AGING POPULATION: IMPLICATIONS FOR PRACTICE

M. Horn Mallers, J. Ruby, *Human Services, CSU Fullerton, Fullerton, California*

Research indicates that the growing population of older adults currently outnumbers the amount of trained persons who can provide assistance. Population growth trends are resulting in a demand for professionals with knowledge and expertise in aging. Unfortunately, many direct workers, or those who already work with or on behalf of older adults, have limited knowledge about gerontology and related practices. Additionally, given other demographic shifts among the aging population, many people are working indirectly with older adults (such as childcare providers given the increase of grandparents rearing grandchildren), or in non-traditional ways (such as therapists treating older adults with addictions, a growing occurrence). Little is known, however, regarding the training and experience of such workers. A baseline understanding of aging-related attitudes and knowledge is therefore critical. The present research is based upon data collected from over 100 professionals, including academic faculty, non-profit personnel psychologists, social workers, day care workers, and graduate students whose work intersects with older adults. Using the Palmore Facts on Aging, Attitudes Toward Older Adults survey (based on Rosencranz & McNevin, 1969), and open-ended questions of previous gerontological experience, preliminary data indicates that many of those surveyed have limited and incorrect factual information about aging or lack motivation and knowledge regarding how to improve aging outcomes. Implications for recruiting and training more professionals in aging-related fields are discussed, as well as mechanisms for educating service providers are provided.

### GENDER, AGE, AND PERSONAL LONGEVITY: HOPES AND FEARS ABOUT LIVING A VERY LONG LIFE

C. Adams-Price[1], L. Morse[3], R. Smith[2], *1. Psychology, Mississippi State University, Mississippi State, Mississippi, 2. University of Georgia, Athens, Georgia, 3. Mississippi State University, Mississippi State, Mississippi*

In previous research, it has been discovered that individuals differ in attitudes about living to advanced old age. The Personal Longevity Scale (e.g., Smith, Adams-Price, Morse, & Giesen, 2006) contains two primary factors, Hopes and Fears. In this study, gender and other predictors of "Hopes" and "Fears" were examined in adults aged 18-92. Results indicated that younger adults were significantly more hopeful about later life than older adults, and women were more hopeful than men. Similarly, men, and especially older men, had significantly more fears about extreme old age. However, there were no gender differences on a separate question about the desire to live to age 100. Older adults were less likely to report that they wanted to live to be 100. The role of health, education, and depression on attitudes toward living a very long life will also be explored.

### AGE DIFFERENCES IN COMPOUND STEREOTYPES ACROSS THE LIFESPAN

C. Andreoletti[1], A. Bruno[1], J.P. Leszczynski[2], *1. Psychology, Central Connecticut State University, New Britain, Connecticut, 2. Eastern Connecticut State University, Willimantic, Connecticut*

Although stereotypes about gender, race, and age have been studied independently, few researchers have examined the content of compound stereotypes, which consider these characteristics together (e.g., White, 25-year-old females). Further, most research on age stereotypes has been limited to old age. To consider gender, race, and age irrespective of one another does little to capture the complexities inherent in social groups. This study examined age differences in the content of compound stereotypes involving gender, race, and age across the lifespan. Using bipolar scales, 70 young (M age = 19.3 years) and 44 older adults (M age = 75.3 years) rated target groups (Black/White, male/female, 15-, 25-, 45-, 65- and 85-year-olds) on 10 characteristics, representative of either an agentic orientation (aggressive, ambitious, skilled at business, competitive, dominant) or a communal orientation (aware of others feelings, considerate, devoted to others, home-oriented, understanding). Preliminary results revealed many interesting main effects and interactions. For example, consistent with traditional gender role stereotypes, young adults perceived male targets as more dominant than female targets, whereas older adults' perceptions of dominance did not vary by target gender. Furthermore, in comparison to young adults, older adults were more likely to perceive White targets as more dominant than Black targets, especially during middle-age (45, 65). By contrast, young adults perceived young (15) and old (85) Black targets as more dominant than White targets.

### ATTITUDES OF NURSING STUDENTS TO OLDER ADULTS

R.M. Phillips, *Nursing, Towson University, Towson, Maryland*

Nurses, and nursing students, can expect to work with older adults during their nursing careers. Nursing students' attitudes to older adults affects overall quality of patient care. Nursing students working with older adults often identify misconceptions and misunderstanding about the older adult population. In addition, many come to nursing with experiences, both positive and negative, that potentially impact this attitude and knowledge. The purpose of this project is to describe the knowledge and attitudes of a group of first year nursing students. Using Kogan's Attitudes toward Aging Scale and an adapted version of the Palmore's Facts on Aging quiz, entry level nursing students were evaluated for attitudes and knowledge of aging prior to their first clinical experience with the older adult and at the conclusion of this experience. Previous interactions with older adults were assessed. Ultimately, this information can be used to revise existing nursing courses or for the development of new nursing courses or clinical experiences.

## MEASURING ATTITUDES TOWARD AGING WITH THE AGING SEMANTIC DIFFERENTIAL: A SAMPLE OF YOUNGER AND OLDER ADULT AFRICAN AMERICANS

B. Brookover[1], A. O'Hanlon[2], *1. Xavier University of Louisiana, New Orleans, Louisiana, 2. University of New Orleans, New Orleans, Louisiana*

Studies on attitudes toward aging have not often examined whether racial differences exist in the attitudes of younger and older adults. Research suggests aging attitudes may differ as studies have reported that African Americans (AA) viewed old age less positively than Caucasian Americans (CA). The present study focused on measuring attitudes of younger and older AA using the Aging Semantic Differential (ASD). Results were also compared to studies employing this scale with predominantly CA samples. The ASD was completed by a sample of 188 AA classified into two groups: 131 younger adult college students (M age = 21) and 57 community-dwelling older adults (M age = 68). Both three factor (Instrumental, Autonomy, Acceptability) and four factor (Instrumental, Autonomy, Acceptability, Integrity) scores were computed for both age groups. Significant age group differences were found on all ASD scores with older adults reporting more favorable attitudes than younger adults, a finding supported in other research. Comparison of three factor scores of the young AA to a sample of young CA revealed no significant racial differences. However, comparison of young AA four factor scores to published research with samples of beginning medical and dental students revealed significant differences for all scores. Medical students reported more positive attitudes than the AA, but dental students reported more negative attitudes. Thus, age group differences in the current study are similar to other research, but additional research should include younger and older groups across race to better examine this issue and explore possible race by age differences.

## ATTITUDE TOWARD AGING IN TWO CULTURES: KOREAN AND AMERICAN VIEWS ON AGING

M. Seo[1], I. Lee[2], B.F. Streets[3], *1. SUNY at Oswego, Oswego, NY, 2. Han-Seo University, Seo-San, Republic of Korea, 3. SUNY Oswego, Oswego, New York*

The purpose of this study was to examine whether attitude toward aging vary by culture and to identify relationships between psychological factors (depression, anxiety, and stress) and attitude toward aging. The participants in this study were a total of 610 American (N = 310, mean age = 20.9, SD = 3.51) and Korean (N = 303, mean age =20.8, SD =3.06 ) college students from a university in central New York and universities in a mid-sized city, Korea respectively. Questionnaires included the Depression, Anxiety and Stress (DASS), the Reaction to Aging (RAQ), and a general questionnaire. Data were analyzed using Pearson correlations, one-way analysis of variance, and multiple regression analyses. Results showed that education was correlated with total attitude toward aging. Compared to Koreans, American young adults showed significantly higher in overall positive attitude toward aging [F (1, 603) = 17.51, P < .000] and a positive aspect of aging [F (1, 603) = 50.74, P < .000]. In addition, Korean young adult showed significantly higher depression [F (1, 609) = .025, P < .000] and anxiety [F (1, 609) = 9.06, P < .003] than American counterparts. Pearson correlations showed that depression, anxiety, and stress were correlated with the total and the three subscale of RAQ. Multiple regression showed that depression is negatively associated with positive attitude toward aging [(F (1, 591) = 1.49, P < .05]. These findings suggest that more intervention programs targeting Korean young adults that facilitate more positive attitude on aging need to be implemented.

## AWARENESS OF AGE-RELATED CHANGE (AARC): DEVELOPMENT OF A SELF-REPORT QUESTIONNAIRE

M.K. Diehl[1], H. Wahl[2], C. Konieczny[2], *1. Human Development & Family Studies, Colorado State University, Fort Collins, Colorado, 2. University of Heidelberg, Heidelberg, Germany*

The experience that one is growing older is a natural part of adult development. The assessment of adults' Awareness of Age-Related Change (AARC), however, has received limited systematic attention. This presentation reports findings from a German study on the development of a self-report questionnaire for the assessment of AARC. The study included 166 adults (58 men, 108 women) with an average age of 53 years (SD = 19 years). Based on semi-structured interviews a total of 60 items were generated to capture positive and negative facets of AARC in 5 behavioral domains: Health and physical functioning, cognitive functioning, interpersonal relations, social-cognitive and social-emotional functioning, and lifestyle and engagement. Analyses showed that the subscales had satisfactory internal consistencies (Cronbach's alphas ranged from .51 to .82). Scores on the positive AARC subscales were mostly uncorrelated with age and personality traits, but were positively associated with several indicators of attitudes towards and satisfaction with one's own aging. Scores on the negative AARC subscales were positively associated with age and neuroticism and negatively associated with extraversion; negative facets were negatively associated with several indicators of attitudes towards one's own aging and the future. Regression analyses, controlling for the effects of age, education and subjective health, showed that positive and negative AARC were significant predictors of aging attitudes and attitude toward one's own future.

## WHAT MAY BE DEPENDS ON WHO I AM: ETHNICITY DIFFERENCES IN ATTITUDES TOWARD AGING

P.W. Foos[1], C. Clark[2], *1. Psychology, University of North Carolina at Charlotte, Charlotte, North Carolina, 2. Queens University of Charlotte, Charlotte, North Carolina*

Given recent research on the importance of positive self perceptions of aging predicting mortality, understanding attitudes toward aging is important. While attitudes have improved, they are not universally positive. This report on gender and ethnic group difference is part of a large scale examination of attitudes toward aging. The sample includes 275 African American (70% female), 122 Asian (56%), 574 White (62%), 86 Hispanic (72%) and 16 Native (75%). The data reported here are from responses made to several questions using a 5-point scale of agreement. Few gender or ethnicity by gender interactions were found, but several ethnic differences emerged. Among differences found were that White Americans believe they will be able to still do most things themselves when they are old F (4, 1041) = 5.72, p < .001 and that they will have plenty to do, F (4, 1041) = 3.68, p < .01. African Americans also believe they will be able to do most things but that they will have little to do. Asian, Hispanic, and Native Americans are most likely to believe that older adults are confused or disoriented while White respondents are the least likely to believe this, F (4, 1043) = 8.23, p < .001. These and other differences to be reported suggest a more positive attitude toward aging on the part of White Americans and more complex, and often more negative views on the part of other ethnic groups. An exploration of why and the implications of these results will be discussed.

## SESSION 640 (POSTER)

## COGNITION I

### MELANCHOLIC DEPRESSION SUBTYPE AND THE RELATIONSHIP TO COGNITIVE FUNCTIONING IN LATE LIFE

E. Corsentino[1], N. Sachs-Ericsson[1], D.C. Steffens[2], *1. Florida State University, Tallahassee, Florida, 2. Duke University, Durham, North Carolina*

Whereas some studies have found prior depressive symptoms to predict cognitive decline (CD) later in life, not all studies have found this association. Methodological differences between these studies may be one important reason for these inconsistent results. Specifically, depression is a heterogeneous disorder, and thus, depression subtype may play an important role in whether or not this relationship is observed. Indeed, melancholic depression has a distinct symptom presentation from other forms of depression, and evidence suggests that melancholic depression has unique effects on the brain and HPA axis. The purpose of the present study was to determine whether participants meeting criteria for melancholic depression would experience greater CD over 5 years compared to individuals with non-melancholic depression and normal healthy controls. Participants consisted of 248 older outpatients at a university medical center with major depression (155 melancholic; 93 non-melancholic) and 147 healthy control participants, and we used latent growth curve analysis to examine differential change in cognitive functioning over time. Comparing the effects of melancholic and non-melancholic depression on CD over time may help us better understand the critical features of depression that confer risk for CD.

### AGE DIFFERENCES IN COGNITIVE WORKLOAD DURING A SIMULATED DRIVING ASSESSMENT COURSE

A. Stinchcombe, S. Gagnon, J. Zhang, P. Montembeault, *University of Ottawa, Ottawa, Ontario, Canada*

Older adults are at a high risk of being implicated in motor vehicle collisions once distance driven is considered. It has been proposed that driving difficulties among this population occur when the driving environment becomes complex, which, in turn, strain attentional resources and increase the opportunity for error. One method of capturing the difficulty associated with driving is through the cognitive workload approach. In this method participants complete a secondary task, known as peripheral detection task (PDT), while driving. The purpose of this study was to explore age-related differences in cognitive workload in response to driving situations of varying complexity within the context of a simulated driving assessment protocol. Consistent with the literature, it was hypothesized that older drivers would demonstrate significantly greater workload in complex situations within the simulated assessment course. Moreover, it was anticipated that older adults would exhibit longer response times in comparison to young and mid-aged drivers. A total of 112 participants belonging to three age groups (young, mid-aged, and older) completed a simulated assessment protocol. While participants drove, they responded to a series of 27 PDT, occurring at a variety of driving situations (e.g., left-turns, right-turns, driving straight, changing lanes, etc). Preliminary analyses indicated that older drivers exhibited significantly greater workload in comparison to the other age cohorts and that workload varied according to complexity for all age groups.

### RELATIONSHIP BETWEEN REASONING ABILITY AND LIST RECALL OVER A 9 YEAR SPAN

S. Hindin, E. Zelinski, *University of Southern California, Los Angeles, California*

Cognitive training studies have suggested that training to increase working memory, which is closely correlated with reasoning, improves recall. Nine-year data from the Long Beach Longitudinal Study were used to test the leading-lagging relationship between reasoning and list recall. Participants tested for the first time in 1994 were included. The sample (N=679) ranged in age from 30-98 (mean=69), 52% female, 75% reported as Caucasian, and 13.8(sd=2.8) mean years of education. Maximum likelihood estimation used all available data. Both reasoning and recall were Rasch-calibrated to a scale of 0-100. We employed cross-lag regression with latent difference scores (LDS) to test the hypothesis that reasoning led recall change. The sample was split into age groups: those over 60 in 1994 (N=504) and those under (N=146). The 60+ group declined from 1994-2003 in letter series (LDS intercept=8.1) and list recall (LDS intercept=14.3). The under-60 group did not experience significant change so their data were not evaluated. Reasoning combined with time one list recall accounted for 18 percent of the variance in the latent list recall difference with good model fit (RMSEA=.03). Model fit was worse for list recall as a predictor of latent reasoning difference (RMSEA=.08). Reasoning leads nine-year latent list recall difference for those 60+.

### AGE DIFFERENCES IN RISK PREFERENCE

T. Queen, T.M. Hess, *Psychology, North Carolina State University, Raleigh, North Carolina*

Young, middle-age, and older adults' preference for risky versus sure outcomes were examined. Participants were presented with 28 gambling situations, half of which were presented in a gain frame and the remaining in a loss frame. The outcomes varied in magnitude, with 7 of the options being large (e.g. receive $400 dollars for sure, or flip a coin to receive $2000) and 7 being smaller (e.g. receive $20 for sure, or flip a coin to receive $100). A risk preference score was calculated for each set of options by examining at which point participants switched from the gamble to the safe option. The overall pattern of performance replicated previous results: Participants expressed a higher preference for risk in the loss frame and a higher preference for the safe choice in the gain frame. An Age Group X Frame X Numeracy interaction was also obtained. Specifically,younger adults with low numeric ability showed no differentiation in risk preference between the gain and loss frames, whereas numeracy played a lesser role in middle aged and older adults' risk preference. Numeracy scores were significantly correlated with vocabulary (r = 0.6) but not working memory or speed, which may indicate an impact of crystallized ability on the task. Further analyses regarding the impact of these abilities will also be reported.

### APOE ε4 STATUS MODERATES THE EFFECT OF HIPPOCAMPAL VOLUME ON COGNITIVE DECLINE IN DEPRESSED OLDER ADULTS

N. Sachs-Ericsson[1], K. Sawyer[1], E. Corsentino[1], N. Collins[1], D.C. Steffens[2], *1. Florida State University, Tallahassee, Florida, 2. Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, North Carolina*

This study examines the ApolipoproteinE epsilon-4 (APOE ε4) allele, hippocampal volume, and their interaction as predictors of cognitive decline in a population of depressed older adults. Both the APOE e4 allele and smaller hippocampal volumes are documented risk factors for cognitive decline; this study adds to the literature by examining the interaction of these two risk factors in predicting cognitive decline. The study examined data from 61 older adult outpatients participating in a longitudinal study at Duke University. At baseline, participants underwent assessment of cognitive functioning (by Mini Mental State Examination), left and right hippocampal volume (by structural MRI of the brain), and APOE genotype. At four-year follow-up, cognitive functioning was re-assessed. Regression analyses were performed to examine the influence of baseline hippocampal volume, APOE ε4 allele status, and their interaction on change in

MMSE score over time. The APOE ε4 allele and left hippocampal volume, but not right hippocampal volume, were independently associated with CD. Importantly, the APOE ε4 allele moderated the effects of left hippocampal volume on CD such that the allele had least effect among those with larger left hippocampal volumes at baseline and greatest effect among those with smaller hippocampal volumes at baseline. Thus, we suggest that future studies of cognitive impairment and decline should examine both individual and conjoint effects of putative risk factors.

### THE FEASIBILITY OF COMPUTERIZED MEMORY TRAINING FOR OLDER ADULTS RESIDING IN INDEPENDENT-LIVING RETIREMENT COMMUNITIES

E.M. Hudak, R. Manno, J. Edwards, *School of Aging Studies, University of South Florida, Tampa, Florida*

Objectives: A pilot study was conducted to examine the feasibility of computerized memory training for older adults using the Dakim BrainFitness system in an independent-living retirement community. Methods: Memory performance was measured by the Auditory Verbal Learning Test (AVLT), Hopkins Verbal Learning Test (HVLT), and WMS-III Family Pictures at baseline and 10 weeks later. Inclusion criteria were a score on the MMSE > = 23, a MoCA score > = 26, and Near Visual Acuity of 20/80 or better. Participants were randomized to either the training (n = 6) or control (n = 5) condition. The training protocol consisted of 25 minute sessions, 5 days a week, over a 10 week period for a total of 20.8 hours. Results: Among those randomized to the training condition, all successfully followed protocol and completed training. Participants trained an average of 21.07 hours with a standard deviation of 3.35 hours. Medium training effect sizes for HVLT (d = .64) and AVLT (d = .53) were observed. However, no potential training gains were evident with the WMS-III Family Picture Test. Conclusions: The Dakim BrainFitness system can feasibly be completed by older adults in independent-living retirement communities and has the potential to improve memory as indicated by HVLT and AVLT. Ongoing data collection will further examine the efficacy of this cognitive intervention.

### PREFERENCES FOR PROFESSIONAL AND SOCIAL COLLABORATORS IN DECISION MAKING

C.L. Ortz, J.M. Jacobs-Lawson, C.C. Gayer, *Gerontology, University of Kentucky, Lexington, Kentucky*

Often when making decisions, older adults seek advice from members of their social network and/or professionals. The purpose of this study was to examine how older adults' preferences for collaboration varied based on the type of decision being made and their gender. Participants (N= 202; age: M = 68.10, SD = 8.25, range 55 - 90) completed a questionnaire assessing their preferences for collaboration when making financial, medical, and purchasing decisions. A 2 (age) x 2 (sex) x 2 (collaborator: professional, social group member) x 3 (decision domain) mixed ANOVA with repeated measures on the latter two variables revealed four significant interactions, three of which involved collaborator. The interactions involving collaborator revealed that (a) age was not related to preferences for a social collaborator but that old participants preferred professional collaboration more than young-old participants; (b) men and women did not differ in terms of preferences for collaborating with a professional but men were more likely to prefer collaborating with a member of their social network; and (c) within medical decisions, participants preferred to collaborate with a professional, but within purchasing decisions, they wanted to collaborate with a member of their social group. The fourth significant interaction revealed that men and women did not differ with respect to preferences for collaboration on financial decisions but that men preferred to collaborate more than women when making medical or purchasing decisions. These results suggest that age, sex, and decision domain are important when examining older adults' preferences for professional and social collaborators.

### THE RELATIONSHIP OF EXECUTIVE AND ADAPTIVE FUNCTIONING TO BEHAVIOR PLANS FOR AGGRESSION IN LONG TERM CARE

M. Smith, C.E. Gould, C.M. Ciliberti, M.R. Nadorff, B. Edelstein, *West Virginia University, Morgantown, West Virginia*

Older adults with dementia or psychotic disorders often exhibit deficits in executive functioning, which can be related to increased aggressive or disinhibited behavior. Royall and colleagues (1992) found that patients with greater executive dysfunction exhibited more aggression and emotional volatility. A chart review was conducted to identify residents of a long-term care facility who were administered the Executive Interview (EXIT-25; n = 79) and the Adult Behavior Adaptive Functioning Scale (AFABS). Data on behavior plans were also collected. The EXIT-25 score was related to the AFABS (r = -.55) in all participants. Neither the AFABS nor EXIT-25 score were related to the presence of a behavior plan to address verbally or physically aggressive behavior. The EXIT-25 score had a small relation with the presence of a behavior plan in participants with a dementia diagnosis(r = .22). The disinhibition factor had a relatively modest relation with the presence of a behavior plan in participants with dementia (r = .27). However, the EXIT-25 score and disinhibition were not related to behavior plans in participants with either a psychotic disorder or a mood disorder. The imitation factor had a small negative relation with behavior plans in participants with a psychotic disorder (r = -.16), and a modest negative relation for participants with a mood disorder (r = -.32). Our findings suggest deficits in executive functioning may be related to behavior plans for aggression in long-term care. The relation between specific deficits in executive functioning and aggressive behavior may vary by type of diagnosis.

### MEASURES OF READING SKILL DISSOCIATE ONLINE READING PROCESSES AMONG OLDER ADULTS

B.R. Payne[1,2], X. Gao[1,2], E. Stine-Morrow[1,2], *1. University of Illinois at Urbana Champaign, Urbana, Illinois, 2. Beckman Institute, Urbana, Illinois*

Among older adults, higher levels of literacy and reading skill are associated with preserved cognitive function, knowledge growth, and self-regulation in reading. However, reading skill is not a homogenous construct. This study focuses on two different measures of reading skill, the Nelson-Denny Reading Test (ND), a speeded measure of reading comprehension (process), and the Author Recognition Test (ART), a measure of print exposure (knowledge), and their relationships to encoding processes and recall in sentence memory among older adults. Participants (N=198, Mean age=72) read sentences word-by-word for immediate recall. Reading times were recorded and decomposed into components representing linguistic processes operating at the word/lexical and semantic (textbase) level. Age was negatively associated with the ND, but not the ART. Patterns of resource allocation to word and textbase processes were differentially predicted by ND and ART scores: high print exposure readers were facilitated only in orthographic processing, suggesting that habitual reading engagement fosters efficiency of lexical decoding; readers with high ND scores were not only facilitated in orthographic processing, but also in lexical access and textbase processing, suggesting that effective reading comprehension with aging is underpinned by efficiency of both lexical and semantic analysis. Controlling for age, verbal working memory, and education, ND and print exposure independently predicted sentence memory. These findings suggest that processing efficiency of component reading skills and knowledge contribute independently to maintaining skilled reading among older readers.

### RELATIONSHIP BETWEEN COGNITIVE ABILITIES AND OUT-OF-HOME MOBILITY IN OLD AGE

M. Wettstein[1], H. Wahl[1], E. Voss[1], F. Oswald[2], M.K. Diehl[3], *1. Ruprecht Karls University, Heidelberg, Germany, 2. Goethe University, Frankfurt, Germany, 3. Colorado State University, Fort Collins, Colorado*

Previous studies have rarely addressed the relationship between out-of-home mobility and cognitive performance in old age in an objective and differentiated way. This is particularly true when it comes to a broader understanding of out-of-home mobility and cognitive impairment. The aim of this presentation is to explore specific links between cognitive performance and out-of-home mobility in cognitively impaired and unimpaired community-dwelling elders. In the project "SenTra" (Senior Tracking), highly differentiated data on out-of-home mobility, assessed with advanced GPS tracking technology, as well as diary-based mobility data are collected over a 4–week period. Furthermore, cognitive functioning, including indicators of fluid and crystallized intelligence, memory, and executive control, is assessed. Preliminary results from mobility diaries of 74 study participants without cognitive impairment (mean age = 69.8 years, SD = 3.8 years) and 42 study participants with mild cognitive impairment and first-stage dementia (mean age = 70.7 years, SD = 5.3 years) show differential relationships between mobility indicators and specific cognitive variables. Specifically, in cognitively unimpaired persons, controlling for age and subjective health, cognition indicators did not predict the mean number of trips per day and mean number of trips by foot per day. However, verbal memory performance significantly predicted the frequency of social and physical out-of-home activities. In the group of cognitively impaired participants, relationships between mobility indicators and cognitive variables were more pronounced. These findings suggest the need to consider complex relationships between cognitive measures and of out-of-home mobility in everyday life among community-dwelling elders.

### MEMORY SELF-EFFICACY PREDICTS LONGITUDINAL CHANGES IN RESOURCE ALLOCATION AND TEXT MEMORY IN SENTENCE READING

X. Gao, B. Payne, E. Stine-Morrow, *University of Illinois at Urbana-Champaign, Urbana, Illinois*

Cross-sectional studies examining adult age differences in sentence processing often find that aging is associated with reduced allocation of attentional resources to conceptual processing and semantic integration (i.e., textbase construction). Such data suggest that differences in reading engagement may contribute to text memory deficits (Stine-Morrow et al., 2008). Meanwhile, other studies indicate meta-cognitive control may partly mediate age differences in memory performance (Dunlosky & Connor, 1997). We report data exploring the role of individual differences in memory self-efficacy in changes in online textbase construction and text memory among older adults. In this study, we tracked longitudinal changes (with a six-month interval) in resource allocation and sentence memory among an older population (N=137; 60-89 yrs, M =72.0, SD=7.3). Participants read 24 18-word sentences as word-by-word reading time was measured, and produced immediately recall. Memory self-efficacy was measured using the Metamemory in Adulthood (MIA) questionnaire (Dixon et al., 1988). Resource allocation to textbase processing was derived using regression to isolate the time allocated to conceptual instantiation and integration. Participants showed reduced resource allocation to textbase construction over time, which was related to reduced sentence recall. Although neither of these effects was associated with age or verbal working memory, elders with higher scores on MIA at pretest were more resistant to declines in textbase allocation with time and showed relatively better sentence recall. These results suggested that meta-cognitive control in later adulthood is crucial to effective attentional allocation in sentence reading and memory performance for text.

### INCREASED DAILY PHYSICAL ACTIVITY MAY HAVE SIGNIFICANT COGNITIVE BENEFIT FOR AFRICAN-AMERICANS

T.R. Patterson[1], S.R. Kennedy[2], J.C. Allaire[1], *1. North Carolina State University, Raleigh, North Carolina, 2. innovation Research and Training, Durham, North Carolina*

The purpose of the current investigation was to examine the within-person relationship between daily physical activity and cognitive performance, specifically within African- American older adults. The sample consisted of 189 community-dwelling older adults (32% African-American, 68% European-American) with a mean age of 73 years (range = 60 – 94; SD = 7.00). Participants were tested over a three-week period, across eight occasions, providing a total of 936 observations. Analyses revealed that there was significant within and between-person variability for overall cognitive performance and physical activity. After controlling for age, gender, income, and general health, multilevel modeling analyses revealed a significant ethnicity X physical activity interaction; on days when individuals reported greater than average within-person levels of physical activity, cognitive performance was significantly greater as compared to days characterized by less than average within-person levels of physical activity. This relationship was stronger in African-American participants, who showed an even greater gain in cognitive performance than did European-Americans.

### NEUROPSYCHOLOGICAL AND FUNCTIONAL COMPARISONS OF OLDER AND YOUNGER ADULTS WITH AND WITHOUT HIV

P.L. Fazeli, D. Vance, L.A. Ross, M.L. Ackerman, *Psychology-Graduate School, University of Alabama at Birmingham, Birmingham, Alabama*

Despite the ability of anti-retroviral viral medications to extend life, those aging with HIV may be more vulnerable to cognitive and functional deficits. In this study, we examined the cognitive and functional performance of younger (21 to 49 years) and older (50+ years) adults with and without HIV. Participants (N = 172) were administered a cognitive battery and the Timed Instrumental Activities of Daily Living test. ANCOVA's were used to test the main effects of age and HIV status and the interaction, after controlling for gender and education. For psychomotor speed, there was a significant effect of age, with those who are younger performing better. For speed of processing, there was a significant main effect of both HIV status and age for 3 measures, with those who are older and HIV-positive performing worse. Another speed of processing measure only yielded HIV status as a main effect, and age emerged as a trend (p =. 06). For the memory and executive functioning domains, no statistically significant differences across groups were detected. In the Timed Instrumental Activities of Daily Living test, there was an HIV x age interaction, as well as a main effect of HIV status, with those who are older with HIV performing worse on such everyday tasks (e.g., looking up a phone number). The results of this study indicate that those with HIV may be at risk of poorer cognitive performance compared to their HIV-negative counterparts and this deficit may transfer to performing everyday tasks.

### BRAIN PATHOLOGY AND MENTAL STATUS: FINDINGS FROM THE GEORGIA CENTENARIAN STUDY

J. Cho[1], P. Martin[1], M. Gearing[2], M. MacDonald[3], J. Margrett[1], R. Green[4], J.L. Woodard[5], L. Poon[6], *1. Iowa State University, Ames, Iowa, 2. Emory University, Atlanta, Georgia, 3. Kansas State University, Manhattan, Kansas, 4. Boston University, Boston, Massachusetts, 5. Wayne State University, Detroit, Michigan, 6. University of Georgia, Athens, Georgia*

This study examined the relationship between brain pathology and cognitive functioning for 45 centenarians of the Georgia Centenarian Study. In terms of brain pathology, Braak stages, amyloid plaques, and a consensus-diagnosis (i.e., agreement between pathology and neuropsychological testing) were included in the analysis. The number of errors of the SPMSQ (Short Portable Mental Status Questionnaire) were used to assess mental status functioning of centenarians. Braak stages were categorized into three groups (low, medium, high). Analysis of variance yielded mean differences for number of errors of the SPMSQ scores for Braak stages, $M = 3.36$ for the stage I&II, $M = 4.53$ for stage III&IV, and $M = 8.31$ for stage V&VI, $F(2, 41) = 10.29, p < .001$; amyloid plaques, $M = 6.03$ for having amyloid plaques and $M = 3.11$ for not having amyloid plaques, $F(1, 41) = 5.52, p < .05$; and the consensus-diagnosis, $M = 5.96$ for those who were diagnosed with Alzheimer's disease, $M = .57$ for normal individuals, and $M = 6.40$ for those with disagreement between pathological and neuropsychological findings, $F(2, 44) = 10.28, p < .001$. Centenarians who were in Braak stage III&IV, with diagnosed amyloid plaques, and who had disagreement between pathological and neuropsychological findings had more errors in SPMSQ than those who were low and medium in Braak stages, and were not diagnosed with amyloid plaques. This result suggests that the SPMSQ is a useful tool for the diagnosis of dementia and specially, highlights high levels of positive relationship between the SPMSQ and Braak stages in very old group.

### THE ASSOCIATION BETWEEN MEMORY AND HEALTH TRAJECTORIES IN LATE ADULTHOOD: THE ROLE OF SOCIOECONOMIC AND RACIAL OR ETHNIC STATUS

K. Kwag[1], K. Wickrama[2], P. Martin[2], J. Lempers[2], *1. University of South Florida, Tampa, Florida, 2. Iowa State University, Ames, Iowa*

The objectives of this study were to examine (a) the cumulative influences of socioeconomic status (SES) and racial or ethnic status on the baseline level and change of trajectories in memory and (b) the dynamic associations between memory and health trajectories during the late adult years. The data for this study come from 5 waves of the Health and Retirement Study (N = 5,710 older adults). We estimated latent growth curves of memory and health problems with predictors. The findings from this study demonstrated that (a) SES and racial or ethnic status had cumulative influences on memory decline over time and (b) trajectories of memory and health problems were associated and influenced each other. Our findings elaborated the long-term progression of memory and health processes.

### BEYOND THE COGNITION/PERCEPTION DICHOTOMY: SOURCES OF AGE-RELATED DECLINES IN SPEECH COMPREHENSION

R.M. Stanley, A. Wingfield, *Neuroscience, Brandeis University, Waltham, Massachusetts*

Older adults often witness a decline in speech comprehension that is especially salient during dynamic social conversations. Many researchers in the psychoacoustics and audiology field cite declines in auditory acuity as the cause for this decline. Researchers in the cognitive psychology field, however, cite changes in cognition as the cause for this decline. Recent literature reviews have proposed that the decline in speech comprehension is due to declines in both perception and cognition, and that future research should take into account the interaction between the two. We will extend the conclusions of previous reviews by presenting a comprehensive model of selective listening that explains age-related declines in terms of specific factors at a multitude of levels. This model will identify specific factors nested within cognition and perception, as well as factors in between. The factors described will include spatial hearing sensitivity, stream segregation cues in the time and frequency domain, attentional speed, inhibitory mechanisms, echoic memory, working memory, short term memory, and long term memory. In addition to describing hypothesized loci of declines, this model will also serve to organize previous research and direct future research by identifying specific testable hypotheses that can be used to ascertain the relative contribution of each of these specific factors. It is hoped that the presentation of this model will also serve to facilitate discussions between people from different fields about factors that contribute to the age-related decline in speech comprehension.

## SESSION 645 (SYMPOSIUM)

### CURRENT LIFESPAN PERSPECTIVES ON EMOTIONAL EXPERIENCES AND COMPETENCIES

Chair: *M. Riediger, Max Planck Research Group "Affect Across the Lifespan", Max Planck Institute for Human Development, Berlin, Germany*

Co-Chair: *A. Rauers, Max Planck Research Group "Affect Across the Lifespan", Max Planck Institute for Human Development, Berlin, Germany*

This symposium focuses on current conceptual and methodological perspectives in investigations of the multi-faceted phenomenon of emotional aging. Various aspects of emotional aging will be addressed, such as age-related differences in processing costs of emotions, in fluctuations of emotional experiences, and in emotional competencies of regulating, expressing, or understanding emotions. The symposium will emphasize the contribution of novel research approaches to the understanding of emotional development. Daniel Gruehn will provide evidence on age-differential processing costs of emotions stemming from an emotion-switching memory paradigm. Shevaun Neupert will present evidence from a diary study showing age-differential effects of daily control beliefs on younger and older adults' fluctuations in emotional experiences. Riediger et al. will demonstrate how a mobile-phone based experience-sampling method was used to investigate age differences in everyday affect-regulation effectiveness. Stanley and Isaacowitz will demonstrate that age differences in physiological responding to emotional material are related to emotion recognition, thus showing how psychophysiological paradigms can be used to further our understanding of emotional aging. Rauers and Riediger, finally, will report on age-related differences in younger and older couples' accuracy in communicating emotions in daily life, using a dyadic experience-sampling approach. Presented empirical results will be discussed with regard to their implications for the field of emotional-aging research.

### EMOTION SWITCHING AS A PARADIGM FOR EMOTION RESEARCH

D. Grühn, *Psychology, NC State University, Raleigh, North Carolina*

Do emotions involve "costs"? Does it take time to switch from one emotional state to another emotional state? Does it take processing resources to activate an emotion? If emotions involve costs, these costs should be apparent when emotions are switched. In an emotion switching memory paradigm, we investigated the effect of switching between positive, negative, and neutral material in 48 young (18-30 years) and 48 older adults (60+ years). In the memory paradigm, participants were presented with six different lists with different lengths of valence-homogeneous pictures. The lengths varied from 1 (mixed), 2, 3, 4, 6, to 12 valence-homogeneous pictures in a row. Pictures were better remembered, the longer the valence-homogeneous sequences were. This indicates that memory is impaired when emotions are switched. The emotion switching paradigm is discussed in the broader context of emotion research and its implication for aging-oriented research.

### AGE DIFFERENCES IN DAILY AFFECT FLUCTUATIONS: DAILY CONTROL BELIEFS MATTER

S.D. Neupert, *North Carolina State University, Raleigh, North Carolina*

While we know from previous research that individual differences in control beliefs are related to emotional well-being, less is known about the daily coupling of these constructs across the adult lifespan. An 8-day daily diary study of 43 older adults and 50 younger adults assessed control beliefs, positive affect, and negative affect. Results revealed no age differences in daily fluctuations (within-person standard deviations) for control beliefs or negative affect, but older adults were less variable in positive affect than younger adults. Subsequent multilevel models revealed a benefit of increased daily control on positive affect for both age groups. However, the daily relationship between daily control and negative affect differed by age; increases in daily control were associated with decreases in negative affect for younger adults, but there was no relationship for older adults. It is possible that older adults rely less on daily contextual variation to regulate their negative affect.

### MASTER OF MY EMOTIONS: DOES AFFECT-REGULATION COMPETENCE INCREASE WITH AGE?

M. Riediger[1], C. Wrzus[1], S. Scheibe[2], G.G. Wagner[3,1], U. Lindenberger[1], *1. Max Planck Research Group "Affect Across the Lifespan", Max Planck Institute for Human Development, Berlin, Germany, 2. Stanford University, Palo Alto, California, 3. German Socio-Economic Panel Study, Berlin, Germany*

Emotional competencies have been claimed to improve with age, but empirical evidence is still scarce. We provided 378 participants aged 14 to 86 years with mobile phones that they carried with them in their natural environment and that prompted them 54 times throughout 3 weeks to report their momentary feelings and whether they wanted to influence them. Lagged multilevel analyses showed that the more participants wanted to maintain positive feelings on a given day, the more stable their positive affect was between that day and the next. Conversely, the more participants wanted to dampen negative feelings, the less stable their negative affect was across days. These associations were moderated by age, suggesting highest effectiveness of maintaining positive affect in older, and of dampening negative affect, in middle adulthood. These results provide first evidence of age differences in the realization of affect-regulatory goals in people's natural environments.

### AGE DIFFERENCES IN EMOTION RECOGNITION AS A FUNCTION OF PHYSIOLOGICAL EXPERIENCE?

J.T. Stanley, D. Isaacowitz, *Brandeis University, Waltham, Massachusetts*

The degree to which someone simulates an emotional expression is related to quality of processing. Twenty-six young and 25 older adults completed, 1) an emotional decoding task identifying facial expressions, and 2) an emotion encoding task watching film clips to elicit facial expressions. Consistent with past work, young adults ($M = 5.15$, $SE = .19$) were more accurate than older adults ($M = 4.12$, $SE = .20$) at recognizing sad expressions, $p < .001$. Young adults' skin conductance levels (SCLs) in the two sad-type tasks were related, $r(26) = .86$, $p < .001$, while older adults' were not, $r(25) = .26$, $p > .05$. For most emotions, both age groups' SCLs were correlated in the two tasks. For sadness, however, older adults may not be instantiating the emotion to the same degree as young adults in the decoding task. Possible motivating factors, like familiarity of the target, will be discussed.

### DO YOU KNOW HOW I FEEL? EMOTION COMMUNICATION IN YOUNGER AND OLDER COUPLES' DAILY LIVES

A. Rauers, M. Riediger, *Max Planck Institute for Human Development, Berlin, Germany*

Does communicating emotional experiences become more difficult with age? Experimental studies suggest that the abilities both to unambiguously express ones own emotional states and to accurately understand emotional expressions in others decrease across adulthood. Although this could possibly impair a person's social adjustment, both individual and relationship functioning are typically preserved into late adulthood. To address this ambiguous evidence, we investigated 50 younger (20–30 years of age), and 50 older (70–80 years) couples' emotion communication in their everyday lives, using cell phones as assessment instruments. Both partners simultaneously rated their current own, and their partners' current emotional states six times daily for 15 days. Overall, younger adults were more accurate in judging their partners' emotions. However, emotion-communication accuracy was differentially associated with situational factors in younger and older couples, suggesting that laboratory settings may underestimate older adults' emotion-communication competencies in everyday life.

## SESSION 650 (SYMPOSIUM)

### DUAL PROCESS MODEL OF BEREAVEMENT: MEANINGS, MEASUREMENT, INTERVENTIONS

Chair: *R. Utz, University of Utah, Salt Lake City, Utah*
Co-Chair: *M. Caserta, University of Utah, Salt Lake City, Utah*
Discussant: *D.A. Lund, California State University, san Bernardino, San Bernardino, California*

The Dual Process Model of Coping with Bereavement (DPM - Stroebe & Schut, 1999) suggests that bereaved persons most effectively cope with loss by oscillating between two processes: one that restores the daily activities and routines of life (restoration-orientation [RO]), and loss-orientation (LO), which addresses the emotional-based needs of the bereaved. This symposium focuses on intervention approaches based on the DPM, the challenges associated with how the processes are measured, and cultural variations surrounding the meaning of the model's constructs. The first paper by Caserta and colleagues will look at longitudinal patterns of loss- and restoration-oriented coping processes between those widow(er)s exposed to a DPM-focused intervention or a primarily loss-oriented traditional support group. Bennett & Evans will focus on measurement of LO/RO and oscillation based on preliminary time-diary and interview data. Chow's paper will discuss conceptual differences in the meaning and measurement of LO and RO processes/tasks based on her development of a DPM-based intervention in China. Finally, the paper led by Utz will look at how the process of grief changes over time between those widow(er)s exposed to a traditional emotion-based support group or an intervention derived from the principles of the DPM theory. Together, these papers suggest how the theoretical principles of the DPM theory may be translated into clinical practice in a way that is sensitive to individual and cultural variations in coping. They further demonstrate the need to be flexible and creative in how the model's constructs are measured and applied.

### COPING PROCESSES AMONG RECENTLY BEREAVED SPOUSES/PARTNERS IN TWO GROUP-BASED STUDY CONDITIONS

M. Caserta[1], R. Utz[1], D.A. Lund[2], B. De Vries[3], *1. University of Utah, Salt Lake City, Utah, 2. California State University - San Bernardino, San Bernardino, California, 3. San Francisco State University, San Francisco, California*

Based on experiences of 328 bereaved spouses/partners (61% Female; M Age = 69.6, SD = 10.6) who participated in the Living After Loss study, we investigated loss- and restoration-oriented (LO/RO) coping among those randomly assigned to an intervention based on Stroebe and Schut's (1999) Dual Process Model (DPM) versus those in a traditional support comparison group. LO coping decreased for both groups up to 9 months following the 14-week group sessions, while an increasing emphasis on RO coping occurred up to the 3-month follow-up (both $p < .01$). These changes were largely independent of group condition with the exception of curvilinear trends ($p = .06$) favoring the DPM treatment. While these observations were consistent with model, the DPM intervention might not have addressed some participants' specific RO needs in order to precipitate a more definitive treatment effect, implying that a more individualized, tailored approach is warranted. (NIA R01 AG023090)

### HOW EFFECTIVE ARE INTERVIEWS AND DAILY DIARIES IN IDENTIFYING THE COMPONENTS OF DUAL PROCESS MODEL OF BEREAVEMENT?

K.M. Bennett, E. Evans, *Psychology, University of Liverpool, Liverpool, United Kingdom*

Stroebe and Schut (1999) propose two types of coping, loss-oriented (LO) and restoration-oriented (RO) with oscillation between them, in their Dual Process Model (DPM) of bereavement. We examined the effectiveness of two methods. An interview asked participants about whether they experienced DPM components. A daily diary asked participants what they were doing, how they were feeling, whether they regarded the activity/feeling as LO, RO or Neutral throughout the day. The interview demonstrated that participants experienced both LO and RO components, but was less effective in identifying oscillation. In contrast, the daily diary gave some sense of daily oscillation. Interestingly, there were experiences which participants classed as Neutral which the researchers would have classified as LO, and there was insight into the triggers which prompted participants to switch from LO activities/thoughts to neutral or RO activities/thoughts. This suggests that it might be possible to teach people techniques for self-regulation.

### CULTURAL ADJUSTMENTS IN DUAL PROCESS MODEL-BASED INTERVENTIONS FOR OLDER WIDOWED ADULTS IN HONG KONG

A.Y. Chow[1,2,3], K. Chan[1,2], E. Koo[1], *1. Dept. of Social Work & Social Adm., The University of Hong Kong, Hong Kong, Hong Kong, 2. CADENZA Project, Hong Kong, Hong Kong, 3. Sau Po Centre on Ageing, Hong Kong, Hong Kong*

The DPM-based intervention applied in the US appears to be promising for Chinese bereaved spouses. A focus group was arranged with clinicians working with bereaved persons to examine the feasibility of adopting the intervention model in Hong Kong. Ideas about adjustments in the content and the length and the patterns of oscillation between loss-oriented (LO) and restoration-oriented (RO) components of the intervention were collected. Specifically, some of the proposed restoration-oriented (RO) components of the intervention such as finances, legal issues and vehicle responsibilities are found to be irrelevant among Chinese. Instead, health issues, cooking and handling relationships are identified as major challenges in the RO dimension. An eight-session model is perceived to be more acceptable than the original 14-session one. Moreover, oscillations between RO and LO components within a session are proposed.

### FOR WHOM CAN GRIEF BE MODIFIED? AN EVALUATION OF THE "LIVING AFTER LOSS" INTERVENTION

R. Utz[1], M. Caserta[1], D.A. Lund[2], B. De Vries[3], *1. University of Utah, Salt Lake City, Utah, 2. California State University - San Bernardino, San Bernardino, California, 3. San Francisco State University, San Francisco, California*

Drawing on 328 older bereaved persons who participated in the "Living After Loss" study, this analysis compares the longitudinal grief experiences of those exposed to a traditional emotion-based support group and those participating in a group-based intervention derived from the Dual Process Model (DPM) of bereavement. Particular emphasis was on which contextual variables moderate the grief trajectories of each group, in hopes of identifying which types of persons and under which circumstances a DPM intervention was most successful. Results indicate that grief trajectories (up to 18 months post-loss) are largely similar across the treatment and control groups, thus indicating that grief may be a fairly universal outcome that is not easily modified by intervention. However, additional analyses found that the DPM-based intervention was particularly effective for those with initially poor mental health and low levels of perceived self-competency, suggesting that intervention ought to be targeted to those persons. (NIA R01-AG023090)

## SESSION 655 (SYMPOSIUM)

### FEAR OF FALLING PROGRAMS: RECRUITMENT, PREFERENCES, MEASURING CHANGE, AND LONG-TERM EFFECTS

Chair: *G. Zijlstra, Maastricht University, CAPHRI - School for Public Health and Primary Care, Maastricht, Netherlands*
Co-Chair: *G.I. Kempen, Maastricht University, CAPHRI - School for Public Health and Primary Care, Maastricht, Netherlands*
Discussant: *E. Peterson, University of Illinois, Department of Occupational Therapy, Chicago, Illinois*

Fear of falling is considered a substantial health problem of equal importance to a fall. Prevalence rates in community-dwelling older adults range from 20 to 60%. In more frail populations, e.g. multiple fallers, prevalence rates are even higher. Particularly if this fear results in activity avoidance, it can lead to physical deconditioning, poor quality of life, institutionalization, and, ironically, increased falls risk. These adverse consequences call for prevention strategies. There is growing evidence for the effectiveness of intervention strategies that comprise cognitive and behavioral components. The limited intervention uptake and compliance by older people is, however, still an issue that needs further study as well as the assessment of change in fear of falling and the long-term effects of existing programs. During this symposium researchers from the US, Germany and the Netherlands will present new data on these issues related to recruitment, preferences, measuring change, and long-term effects of fear of falling programs. First, the recruitment of community-dwelling older adults for the "Stay Active" program will be discussed in light of participants' characteristics. Second, older adults' preferences regarding different formats of interventions, e.g. home-based vs. community-based, were determined in over 1,100 older community-dwellers. Third, the sensitivity-of-change of three scales assessing concerns about falling was analyzed in patients with dementia. And lastly, the long-term effects of a multicomponent cognitive behavioral intervention on mortality and fear of falling are presented. Our discussant will reflect on the presentations and facilitate a discussion on-site.

### RECRUITMENT FOR A FEAR OF FALLING EDUCATION AND COACHING INTERVENTION

H. Lach, D.C. Sundara, *Saint Louis University, St. Louis, Missouri*

This paper reports on recruiting for an education and coaching pilot intervention study for fear of falling. Community-dwelling subjects were recruited from 4 sites for a study to help them stay active (N=41, mean age 79.4+5.7, 90.5% female, 14% married, 81% White,). Potential participants had to have either significant concerns about falling (32%), balance problems (34%), or both (34%). Other inclusions were ability to read and speak English and transportation availability. Exclusions were cognitive impairment or depression, or severe visual or mobility problems. 43% of interested participants met criteria. Baseline assessment included measures of fear of falling, falls self efficacy and outcome expectancy, ADL/IADLs, activity levels and performance testing of mobility and balance. Participants recruited through community center sites were easier to recruit, and had higher levels of function and activity than those recruited through senior centers with meal sites and bus service. Supported by NINR-R15NRO10792.

### PREFERENCES REGARDING INTERVENTION FORMATS OF COMMUNITY-DWELLING OLDER ADULTS WITH FEAR OF FALLING

T. Dorresteijn[1], G. Zijlstra[1], Y. Van Eijs[1], J. Vlaeyen[2,3], G.I. Kempen[1], *1. Maastricht University, CAPHRI School for Public Health and Primary Care, Maastricht, Limburg, Netherlands, 2. University of Leuven, Research Group Health Psychology, Leuven, Vlaams Brabant, Belgium, 3. Maastricht University, Department of Clinical Psychological Science, Maastricht, Limburg, Netherlands*

Objective. To determine older adults' preferences regarding different formats of interventions aimed at reducing fear of falling. Methods. A questionnaire was sent to 2,550 community-dwelling people ≥70 years randomly selected from municipal registry offices (response complete questionnaires: 45%). The questionnaire assessed the extent of fear of falling and related activity avoidance, and willingness to take part in an home-based individualized or a local group intervention. Results. Nearly 40% of the people with fear of falling preferred to participate in a home-based intervention while 25% preferred to participate in a group intervention. Compared to people with no fear of falling, those who are sometimes or often afraid of falling are three times more likely to participate in an home-based intervention (OR=2.96; 95%CI=1.57-5.58) and two times more likely to participate in a group intervention (OR=1.98; 95%CI=1.00-3.90). Conclusion. To meet participants' preferences fear of falling programs may put more emphasis on home-based approaches.

### RESPONSIVENESS OF MEASURES ON FEAR OF FALLING IN PATIENTS WITH DEMENTIA

K.A. Hauer[1], G.I. Kempen[2], G. Zijlstra[2], M. Schwenk[1], L. Yardley[3], N. Beyer[4], C. Todd[5], *1. Geriatric Research, Bethanien-Hospital at the University of Heidelberg, Heidelberg, Germany, 2. School for Public Health and Primary Care – CAPHRI, Department of Health Care and Nursing Science, Maastricht University, Maastricht, Netherlands, 3. School of Psychology, University of Southampton, Southampton, United Kingdom, 4. Institute of Sports Medicine, Bispebjerg Hospital University of Copenhagen, Copenhagen, Denmark, 5. School of Nursing, Midwifery and Social Work, University of Manchester, Manchester, United Kingdom*

Research on fall-related psychological consequences has so far been limited by the lack of evaluation tools validated for people with dementia. The aim of this study was to determine the responsiveness of three scales that assess concerns about falling in patients with diagnostically confirmed beginning to moderate dementia who participated in an RCT (N=113). The scales included the 16-item Falls Efficacy Scale International (FES-I), the 7-item Short FES-I, and the 10-item Falls Efficacy Scale (FES). All scales showed moderate to excellent sensitivity-to-change. The overall range for effect sizes (ES) was .14-1.17 (FES-I=.18-.88; Short FES-I=.14-1.17; FES=.15-.91;). The Short FES-I showed the highest peak responsiveness. When only fear-affected patients were included in the analyses, excellent responsiveness was documented (FES-I=.88; Short FES-I=1.17; FES=.91). The results of this study indicate moderate to excellent responsiveness for the FES-I, Short FES-I, and FES in patients with dementia if applying an interview-based administration of the scales.

### LONG-TERM INTERVENTION EFFECTS ON MORTALITY AND FEAR OF FALLING IN OLDER ADULTS: AN RCT

G.I. Kempen, S. Oude Wesselink, J.C. van Haastregt, G. Zijlstra, *School for Public Health and Primary Care, Maastricht University, Maastricht, Netherlands*

A multicomponent cognitive behavioral group intervention to reduce fear of falling and associated activity avoidance was evaluated in a randomized controlled trial in the Netherlands. Community-dwelling people aged 70 or over experiencing at least some fear of falling and associated activity avoidance were eligible for study. Participants (N=540) were randomly allocated to either intervention or control group. The intervention comprised eight weekly sessions of two hours and a booster session after six months. The control group received no intervention. Data was collected at baseline, and at 2, 8 and 14 months. The results showed significant outcomes at 14 months on fear of falling (OR=0.31; p<0.01) perceived control over falling (mean difference=0.90; p<0.01) and recurrent falls (OR=0.38; p=0.02). In this paper particularly the long-term intervention effects on mortality, i.e. survivorship at 6 years, will be presented and discussed.

## SESSION 660 (POSTER)

## HUMAN DEVELOPMENT

### TOWARD A DISCOURSE SHIFT IN GERONTOLOGY: FROM "SUCCESSFUL AGING" TO "HARMONIOUS AGING

J.J. Liang, *MU,Ohio, Oxford, Ohio*

"Successful aging," though controversial, is commonly used as an overarching framework in gerontology. In this conceptual essay, "successful aging" is identified as problematic in three dimensions. First, "successful aging" tends to deny old age by advocating "agelessness"; and it fails to face up to the "shadow side of aging." Second, "successful aging" embodies an unrecognized, problematic component of consumerism which is not explicitly addressed. Third, "successful aging" overlooks the deeper concern of quality in the face of the quantified standardization of what constitutes "successful." Fourth, "successful aging" is based on the "busy ethic" emphasized within American culture and thus, may not be applicable to outside cultures. The proposed discourse of "harmonious aging" is inspired by the Yin-Yang philosophy—Yin and Yang are the two forces of harmony and change; they are opposite yet interdependent. "Harmony" refers to balance based on the acknowledgment of differences instead of insisting on sameness. The discourse of "harmonious aging" aims to provide a more comprehensive framework by incorporating activity theory and disengagement theory, to address the feminist concern of the "double standard of aging," and to recognize the challenges and opportunities of old age itself. This new discourse attempts to promote intellectual exploration of what constitutes a good old age and to capture more cross-cultural diversities in the context of global aging. This theoretical endeavor is important to change the status quo of gerontology, which is often described as "data rich but theory poor." This work will also contribute to cross-cultural gerontological education and communication.

### SPIRITUAL AWAKENING AND EGO-INTEGRATION: AN ERIKSONIAN INTERPRETATION OF EBENEZER SCROOGE

G. Washlow Kaufman, M. Takahashi, *Psychology, Northeastern Illinois University, Chicago, Illinois*

In this paper, Ebenezer Scrooge, the protagonist in Charles Dickens's A Christmas Carol, is examined from an Eriksonian perspective as he goes through a process of spiritual awakening and ego integration. The parallels between Ebenezer Scrooge's path toward enlightenment and the developmental crises that define stage transitions in the Eriksonian model are examined in detail through the literary device of spiritual visitation allowing the reader to understand Scrooge's life history. With the "Ghost of Christmas Past," Scrooge reviews his childhood, young adulthood and early maturity representing Erikson's development stages of trust, autonomy, initiative, industry, and identity at which Scrooge's psychosocial maturity ceased and he became locked in despair causing fear and social isolation that clouded his adult life. The visitation of the "Ghost of Christmas Present" forces Scrooge to confront his past mistakes and limitations, offering him hope of possible resolution to his developmental crises. The arrival of the "Ghost of Christmas Yet to Come," forces Scrooge to either work toward enlightenment or stagnate in despair, to be summarily forgotten or to be fondly remembered. Scrooge's experience with the visiting spirits takes him through Erikson's model through to the seventh stage of

"Generativity." Additional insights and parallel discussion of elements of Horney, Levinson, Frankl and Moody and Carroll are interposed to underscore the remarkably close relationship between Dickens' narrative and Erikson's theory of the potentiality of psychological growth in the older adult.

### THE CHARACTERISTICS OF GEROTRANSCENDENCE IN FRAIL OLDEST-OLD INDIVIDUALS WHO MAINTAIN A HIGH LEVEL OF PSYCHOLOGICAL WELL-BEING

Y. Masui[1], Y. Gondo[2], M. Takayama[3], Y. Kureta[4], T. Nakagawa[2], R. Takahashi[1], H. Imuta[5], *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, 2. Osaka University, Osaka, Japan, 3. Keio University, Tokyo, Japan, 4. Showa University, Tokyo, Japan, 5. Tokyo Metropolitan University, Tokyo, Japan*

The purpose of this study was to develop a new questionnaire to investigate gerotranscendence in Japanese elderly individuals aged 65 yr and over, and to clarify the characteristics of gerotranscendence in physically frail but emotionally adapted oldest-old aged 85 yr and over. We developed the new questionnaire on the basis of interviews with 10 elderly individuals, and employed the questionnaire on 500 community-dwelling elderly (men 198, women 302). Factor analysis of the questionnaire suggested an eight-factor solution that included "Awareness of arigatasa and okage", which is a concept in Japanese culture that all people and living creatures are inter-dependent, "Introversion", "Transcendence from dualism", "Religious/Spiritual attitude", "Release from the social self", "Basic and innate affirmation", "Altruism", and "Let it go". Using cluster analysis, we classified the 149 community-dwelling oldest old (men 51, women 98) into three groups: a group with high function and high well-being (HF-HWB), a group with low function and high well-being (LF- HWB), and a group with low function and low well-being (LF-LWB). "Introversion", "Release from the social self", and "Let it go" in the LF-HWB group were significantly higher than those in the LF-LWB group, and the score for "Religious/Spiritual attitude" was significantly lower in the former than in the latter. These results suggest that some gerotranscendence factors are important for maintenance of psychological well-being in the frail oldest-old.

### REASONS FOR LIVING AMONG EUROPEAN AMERICAN, AFRICAN AMERICAN, AND LATINO OLDER ADULTS

A. June, D.L. Segal, A. Murphy, F.L. Coolidge, *University of Colorado at Colorado Springs, Colorado Springs, Colorado*

The purpose of the present study was to explore how potential reasons for not completing suicide may differ among several ethnic groups. Community-dwelling older African American adults (n = 35; 66% female; M age = 71.1 years, SD = 7.2 years), Latino adults (n = 26; 52% female; M age = 70.2 years, SD = 7.0 years), and European American adults (n = 37; 51% female; M age = 67.7 years, SD = 6.5 years) anonymously completed the Reasons for Living Inventory (RFL). An ANOVA was performed comparing these ethnic groups on the RFL total and each subscale. Significant differences between groups ($p < .05$) were found on the Child-Related Concerns subscale, $F(2, 94) = 4.45$, the Fear of Suicide subscale, $F(2, 90) = 5.44$, and the Moral Objections subscale, $F(2, 96) = 8.28$. Post-hoc analyses on the Child-Related Concerns subscale revealed that African Americans (M = 4.10, SD = 1.73) scored significantly lower than European Americans (M = 4.76, SD = 1.10) and Latinos (M = 5.12, SD = 1.02). On the Fear of Suicide subscale, European Americans (M = 1.81, SD = 0.84) scored significantly lower than African Americans (M = 2.33, SD = 1.12) and Latinos (M = 2.76, SD = 1.28). Finally, post-hoc comparisons on the Moral Objections subscale indicated that European Americans (M = 3.89, SD = 1.48) scored significantly lower than African Americans (M = 5.08, SD = 1.15) and Latinos (M = 4.82, SD = 1.21). Implications of these findings are discussed.

## SESSION 665 (SYMPOSIUM)

### INTERNATIONAL PERSPECTIVES ON RETIREMENT AND RETIREMENT PLANNING

Chair: *H. Van Solinge, Netherlands Interdisciplinary Demographic Institute, The Hague, Netherlands*
Co-Chair: *D.A. Hershey, Oklahoma State University, Stillwater, Oklahoma*
Discussant: *J. Hendricks, Oregon State University, Corvalis, Oregon*

Since the early 1990s, pension reform has been high on the agenda in almost all developed countries. Governments have either undertaken far-reaching, structural pension reforms or adopted a series of small reforms which, taken together, affect future pension entitlements substantially. These reforms have included, among other things, increases in pension ages, changes in the way benefits are calculated and smaller real pension increases than in the past. However, despite the different approaches, there is a clear underlying trend toward a reduced pension promise for today's workers, relative to past generations. Recent pension reforms mean – directly or indirectly – that in the future private savings and pensions will play a greater role in providing incomes in old age. Although this shift in responsibility for pension saving from the state to the individual can be witnessed throughout the Western world, the impact on individual workers may differ, depending on the architecture of the national 'pension building' strategy, the pace of change in the reforms, and cross-cultural differences in retirement planning and saving behavior. The broad goal of this symposium is to examine the psychological, social and economic factors that influence planning and saving for retirement. These behavioral determinants will be considered from both international and cross-cultural perspectives, by panelists drawn from various disciplines living in different parts of the world.

### FINANCIAL PLANNING FOR RETIREMENT: INTERDISCIPLINARY INFLUENCES VIEWED THROUGH A CROSS-CULTURAL LENS

D.A. Hershey, *Psychology, Oklahoma State University, Stillwater, Oklahoma*

Current theoretical models support the existence of interactions between the individual and socio-environmental forces when it comes to the formation and enactment of life plans (Shanahan & Elder, 2002). In this investigation, we examined the social, psychological and economic dimensions that impact financial planning for retirement. The collective force of these three sets of influences was studied from a cross-cultural perspective, among respondents from two countries with very different retirement financing systems. Participants were 419 American and 556 Dutch working adults, 25-64 years of age. Country-specific path analytic models revealed clear psychological differences in planning orientation across nations, as well as differences in both the social support mechanisms that underlie planning and the impact economic forces have on perceptions of saving adequacy. The discussion will focus on the value of constructing interdisciplinary models of planning, and how such models can inform the development of saving interventions and public policy initiatives.

### INDIVIDUAL AND INSTITUTIONAL RESPONSE TO THE GLOBAL FINANCIAL CRISIS: AUSTRALIAN RETIREMENT INCOME SYSTEM EVIDENCE

P. Gerrans, *1. Edith Cowan University, Joondalup, Western Australia, Australia, 2. Centre for Retirement Incomes and Financial Education Research, Joondalup, Western Australia, Australia*

For much of the 20th century Australia relied on a state-based pension as a central pillar of its retirement income system, supplemented by a second voluntary savings pillar. A third occupation-linked savings pillar, known locally as superannuation, existed but was confined to white collar workers until late in the 20th century. This pillar was strengthened, and widespread superannuation coverage emerged, in the

1980s and was entrenched through legislation in 1992 requiring employers contribute three percent of wages, and since 2002 nine percent, on behalf of employees to a superannuation account. A feature of superannuation is its concentration in defined contribution schemes where investment risk is borne by the individual, not pooled as with defined benefit funds. The global financial crisis represented a substantial challenge as individuals watched their balances drop significantly and rapidly. This paper describes how the system and individuals responded to the crisis and reflects on lessons available.

### WHAT DRIVES PENSION WORRIES IN EUROPE? A MULTILEVEL ANALYSIS

K. Henkens[1,2], H. van Dalen[1,3], *1. NIDI, The Hague, Netherlands, 2. Department of Sociology, Tilburg University, Tilburg, Netherlands, 3. department of Economics, Tilburg University, Tilburg, Netherlands*

This paper studies individuals' worry about their financial future in retirement, and the extent to which they take active steps to save in order to ensure an adequate standard of living. In this study, we analyze data from the third wave of the European Social Survey, which represents 22,609 working adults from 23 countries in Europe. We used multilevel modelling to focus on the explanatory factors that underlie individual and country-level effects in future pension worry and saving behavior. Findings suggest that once individual-level dimensions are taken into account, country-level predictors explain appreciable variance in worry, but not saving practices. Pension worries are more severe in countries with a low retirement age and a strong projected increase in future population aging. This suggests that the drive toward raising the retirement age in a number of EU countries may alleviate some of the worries of its citizens.

### BRAZILIAN RETIREMENT PLANNING PROGRAMS

L.H. Franca, *Graduate Studies in Psychology, UNIVERSO - Salgado de Oliveira University, Niterói, Rio de Janeiro, Brazil*

The Brazilian Social Welfare Reform was implemented in 2003, although the system is still marked by inequalities by life expectancies amongst States (66.2 to 75.6 yrs), the different pensions (public and private sectors) and the large percentage of non-formal workers (49,4%) who do not pay Social Welfare. In spite of these differences, for many workers State Pension is the only means of retirement survival. Economical, cultural and psychosocial aspects influence the Brazilian habit of (not) planning for the future, such as super-inflation (1980-1994). At present, with a stable economy, private financial organizations try to encourage the population to adopt individual financial planning. According to Brazilian Law, in order to guarantee the well-being for retirees, Retirement Planning Programs should be proposed by private organizations. In this presentation I shall discuss retirement planning programs (Retirement Planning seminars) and their key factors as developed by Brazilian organizations.

## SESSION 670 (SYMPOSIUM)

### MY GLASS IS HALF FULL: POSITIVE GRANDPARENT CAREGIVING

Chair: *B. Hayslip, Psychology, University of North Texas, Denton, Texas*
Discussant: *C. Musil, Case Western Reserve University, Cleveland, Ohio*

Work on grandparent caregivers often reflects a negative bias in documenting the difficulties such persons face, focusing upon the negative impact (depression, poor health) of caregiving on them. This symposium takes a positive approach to understanding grandparent caregivers in emphasizing their resilience and resourcefulness, stressing a strengths-based approach to caregiving as well as both benefit finding and positive coping in characterizing many grandparent caregivers. Hayslip, Neumann, and Davis stress the mediating role of resilience in explaining the relationship between both grandchild characteristics and life stressors in predicting grandparent caregiver well-being over a 1-year time frame. Smith examines the relationship between both positive well-being and positive self-appraisals and grandchild well-being, as well as the mediating role of parenting practices (warm and discipline) in explaining this relationship. The work by Bailey, Letiecq, and Erickson stress the understanding and development of coping strategies leading to positive grandparent outcomes based upon interview data of rural grandparent caregivers. Smith and Dannison present findings from the Grandparents Resources Site Project, a 30 month long intervention that capitalizes on grandparent caregivers' inherent strengths in helping them enhance networks of social support. Last, Goodman explicates the roles of personal (resilience) and social (family and friend support, maintaining positive grandchild relationships) influences on grandparent caregiver well-being, after the children they raised have grown. Carol Musil, the discussant, who conducts research emphasizing resourcefulness among grandparent caregivers will integrate findings from these papers in stressing the positive, adaptive qualities grandparents rely upon to cope and prosper in the face of adversity.

### THE ROLE OF RESILIENCE IN MEDIATING LONGITUDINALLY ASSESSED GRANDPARENT OUTCOMES: A 1-YEAR ANALYSIS

B. Hayslip[1], C. Neumann[2], S.R. Davis[2], *1. Psychology, University of North Texas, Denton, Texas, 2. University of North Texas, Denton, Texas*

Based upon previous cross sectional data utilizing OLS regression techniques underscoring the mediating role of resilience in explaining the relationship between child characteristics and life stresses and grandparent parental stress/efficacy and personal well-being, 1-year longitudinal data collected from grandparent caregivers (n = 86) regarding the latter indices of grandparent parental and personal functioning were analyzed utilizing structural equation modeling (EQS). Modeling of longitudinal data suggested that the latent construct of resilience at T1 continued to mediate the relationship between latent constructs reflecting both grandchild strengths and difficulties and a similarly modeled life stress construct at T1, and multiple indices defining the latent constructs of grandparent caregiver parental efficacy/stress and psychological well-being at T2; they were also confirmed utilizing OLS regression analysis. They therefore strengthen previous findings centralizing resilience in enhancing the parental and personal functioning of grandparent caregivers, and suggest that interventions targeting resilience may have long term positive effects.

### PATHWAYS TO RESILIENT GRANDFAMILIES IN RURAL AREAS

S. Bailey, B. Letiecq, M.R. Erickson, *Health & Human Development, Montana State University, Bozeman, Montana*

Drawing from research on grandfamilies, this project examined pathways that grandparent caregivers take in adapting to their new roles and family configuration. Based upon a study of 26 in-depth family life history interviews and constructed genograms of grandfamilies in a rural western state, processes that led to positive outcomes for grandparent caregivers and their families were examined. Guided by the Double ABCX Model of family stress and crisis, we found every family in our study in crisis when they took over care of their grandchildren. In the context of resilient grandfamilies, we found grandparents who began with and maintained a positive attitude about the situation and utilized available resources, coped better than those who did not. Grandparents with better coping were those who shifted roles, identities, relationships, and perceptions of the situation. Such data are key to the development of strategies for practitioners working with grandparent-headed families.

### SECOND TIME AROUND: STRENGTHS-BASED PROGRAMMING FOR GRANDPARENT CAREGIVERS

A.B. Smith, L.L. Dannison, *Teaching, Learning and Educational Studies, Western Michigan University, Kalamazoo, Michigan*

The Grandparent Resource Site Project provided supportive and educational services to relative caregivers in multiple sites over a 2 ½ year period. Services were arranged in a tiered delivery system, allowing sites and Local Advisory Committees to select services based on community needs and existing resources. Grandparent caregivers participated in 8-12 week educational groups, receiving information, support and socialization opportunities. It was found that the benefits of a strengths-based program included: increased perceptions of grandparent caregivers' abilities to cope with stress, increased abilities to meet their grandchildren's needs, increased feelings of pride in raising their grandchildren, increased feelings of positivity about their own lives, increased meaning their lives due to raising their grandchildren, and the perception that it was more rewarding than stressful to raise their grandchildren. These results underscore the importance of stressing family strengths and providing grandparent caregivers with strategies for meeting the challenges of raising a grandchild.

### A TWO FACTOR MODEL OF OUTCOMES FOR CUSTODIAL GRANDMOTHERS AND GRANDCHILDREN

G. Smith, *Lifespan Development & Educational Sciences, kent state university, Kent, Ohio*

No work has been conducted on how positive mental health and parenting practices of grandparent caregivers is related to grandchildren's psychological strengths. Within a two-factor model of caregiver appraisal and psychological well-being, data were collected from a large national sample (n = 733) of custodial grandfamilies. Structural equation modeling findings suggested that 1) the effects of custodial grandmothers' distress and positive well-being on grandchildren's adjustment were both mediated by parenting practices (warmth and discipline), 2) both negative and positive caregiver self-appraisals directly affected caregiver distress and positive-well being; and 3) the impact of a grandmother's negative appraisals of caregiving on her psychological well-being is considerably greater than the corresponding impact of positive appraisals. Thus, the adjustment of custodial grandchildren is linked to both the positive and negative emotional well-being of grandparents. Lessening negative caregiver appraisals is critical to reducing distress and enhancing positive well-being among grandparent caregivers.

### SOCIAL AND PERSONAL RESOURCES OF GRANDMOTHER CAREGIVERS AFTER GRANDCHILDREN ARE GROWN: A PILOT STUDY

C. Goodman[1], D. Scorzo[2], P. Ernandes[3], A. Alvarez-Nunez[4], *1. Department of Social Work, California State University, Long Beach, Long Beach, California, 2. Cambrian Home Care, Long Beach, California, 3. Southern California Permanente Medical Center, Downey, California, 4. Pacific Clinics, Long Beach, California*

Little is known about grandparent caregivers' well-being after their grandchildren have grown. This pilot study addressed the factors related to the well-being of grandmother caregivers who had raised grandchildren in terms of their personal resources (resilience and satisfaction with the grandparent role) and social resources (instrumental and subjective support from family/friends and from their grandchild). Grandmothers' self-assessment of personal resilience and their satisfaction with having raised their grandchildren were related to better mental health and greater life satisfaction, and a close relationship to grandchildren was related to better mental health and less depression. In contrast, instrumental support from grandchildren was negatively related to health. Additionally, subjective social support was related to greater life satisfaction and receiving instrumental support from family and friends was related to lower depression. Results emphasize the importance of personal and social resources for aging grandmother caregivers, especially the ongoing benefit from close relationships with grandchildren.

## SESSION 675 (SYMPOSIUM)

### NIMH UPDATE: CURRENT PRIORITIES AND OPPORTUNITIES IN MENTAL HEALTH AND AGING RESEARCH

Chair: *G. Niederehe, Geriatrics Research Branch, National Institute of Mental Health, Bethesda, Maryland*

Co-Chair: *J. Evans, Geriatrics Research Branch, National Institute of Mental Health, Bethesda, Maryland*

In this session, National Institute of Mental Health (NIMH) staff members will describe current priorities for the Institute, inform the audience of NIMH programs that support research efforts on aging and mental health, and outline particular areas of opportunity for new studies. The initial presentation will discuss the current funding context at the National Institutes of Health and NIMH, including trends, recent developments, and changes in the business practices affecting the review and award process for grant applications, and provide an overview of how funding programs at NIMH are organized. Particular emphasis will be placed on the NIMH Strategic Plan as a central impetus for current priorities, on new assessment approaches that have been advanced for use in clinical research, and on the report of an NIMH Advisory Council workgroup recommending new directions in intervention research. The subsequent presentations will describe the various areas in which the NIMH Geriatrics Research Branch supports studies of mental health and aging, and particular interests and priorities relating to these areas, which include programs on Translational Behavioral Science, Translational Neuroscience, Pharmacologic Intervention Research, and Psychosocial Intervention Research, and Multi-Modality Intervention Research. The final portion of the session will be a question and answer period during which audience members will be encouraged to ask questions and identify issues of particular interest for interactive discussion.

### THE NIH CONTEXT: TRENDS, RECENT DEVELOPMENTS, AND THE GRANTS PROCESS

G. Niederehe, *Geriatrics Research Branch, National Institute of Mental Health, Bethesda, Maryland*

This presentation will describe the current research funding context at NIH and NIMH for proposing projects on mental health and aging, both in terms of long-term trends and recent events. This will include the status of the Congressional appropriations process for the coming year, and other special initiatives or situational elements that may bear upon aging-related research (such as recent NIH Funding Opportunity Announcements, noteworthy recent scientific advances, organizational changes, or the like). Particular emphasis will be placed on the centrality of the NIMH Strategic Plan in prompting current Institute priorities. This presentation will also cover how funding programs are organized at NIMH, typical funding mechanisms, forms of support available for aspiring investigators in early stages of a research career, and the basic steps in applying for an NIH grant, including recent changes in the length and format of applications and in the grants review process.

### OPPORTUNITIES AND NEW DIRECTIONS IN TRANSLATIONAL NEUROSCIENCE AND BEHAVIORAL SCIENCE RESEARCH IN GERIATRIC MENTAL HEALTH

J. Evans, *National Institute of Mental Health, Bethesda, Maryland*

This presentation will discuss NIMH efforts to expand its geriatric translational research programs and highlight areas of particular opportunity for advancing the neuroscience and behavioral science of late-life mental disorders. Themes to be emphasized will include: studies directed at clarifying the neural circuits and biological processes associated with mental disorders in later life; the desirability of integrating genetic, brain imaging, and other technologies (e.g., cognitive and affective neuroscience) to advance a mechanistic understanding of disorder pathophysiology; new approaches to assessing symptomatic or functional domains that cut across traditional diagnoses; the importance of studying how specific aspects of the biological aging process interact with the trajectories of neurobiological changes seen in chronic mental disorders as affected individuals age; and studies aimed at identifying biomarkers indicative of vulnerability to developing mental disorder in late life or useful in tracking the progression of underlying disease processes over time.

### OPPORTUNITIES AND NEW DIRECTIONS IN GERIATRIC MENTAL HEALTH INTERVENTION RESEARCH

G. Niederehe, J. Evans, *Geriatrics Research Branch, National Institute of Mental Health, Bethesda, Maryland*

This presentation will review the priorities for and types of research supported by the Pharmacologic Intervention, Psychosocial Intervention, and Multi-Modality Intervention research programs within the NIMH Geriatrics Research Branch. Areas to be discussed will include the recommendations of an NIMH Advisory Council work group on new directions in intervention research, and the increasing priority placed on intervention studies that examine various avenues to personalizing care for older adults with mental disorders. The latter may include studies of modularized interventions and stepped care approaches, as well as studies of potential predictors of the individual's response to varied treatment options. The presenter will discuss NIMH viewpoints on and priority given to the development of innovative new treatments, and also to research that instead proposes to modify or adapt existing treatment approaches (e.g., to increase their cultural sensitivity, their applicability in typical care settings, and/or their uptake and use by typical providers).

## SESSION 680 (SYMPOSIUM)

### PATTERNS OF ADJUSTMENT IN MIDDLE-AGED AND OLDER ADVANCED CANCER PATIENTS AND CAREGIVERS OVER TIME

Chair: *J.H. Rose, Medicine, Case Western Reserve University, Cleveland, Ohio*
Co-Chair: *K.F. Bowman, Medicine, Case Western Reserve University, Cleveland, Ohio*

A diagnosis of late-stage cancer is highly stressful and newly diagnosed patients have been shown to differ by age in wellbeing and care preferences. However little is known about age-related adjustment in survivors over the first year after diagnosis, described as the early treatment phase for late-stage cancer. Patterns of adjustment may differ over this period for middle-aged (MA) patients in their 40s and 50s versus young-old (YO) patients in their 60s and 70s. This symposium reports exploratory findings of MA and YO patients and their caregivers in a large randomized controlled longitudinal study. The Kypriotakis paper uses multiple group analysis and general growth mixture modeling to evaluate whether depressed mood trajectories of MA and YO advanced cancer patients and their association to patient characteristics and family caregiver depressed mood levels vary by age group. Using similar methods, the Step paper examines trajectories for MA and YO recurrent and non-recurrent patients reporting age group interactions with recurrence status for anxiety, depressed mood and symptom distress. The Phillips-Towe paper uses latent class analysis to explore variation in preference for cardiopulmonary resuscitation in MA and YO advanced lung cancer patients. The Francis paper examines patterns of bereavement in caregivers of deceased MA and YO patients and the association between caregiver and patient factors and bereavement outcomes for caregivers of patients in the two age groups. Overall findings on differences in patterns of wellbeing and care preference for MA versus YO groups are highlighted. Implications and future directions for research will be discussed.

### A COMPARISON OF MIDDLE-AGED AND YOUNG-OLD'S DEPRESSED-MOOD TRAJECTORIES WITH ANTECEDENTS OF CHANGE

G. Kypriotakis, K.F. Bowman, J.H. Rose, *Case Western Reserve University, Rocky River, Ohio*

Multiple group analysis and general growth mixture modeling were used to evaluate whether depressed mood trajectories of advanced cancer patients and their association to patient characteristics and family caregiver depressed mood levels vary by age group. Patients were assessed at baseline, 3, 6 and 12 months. Three trajectories were identified for middle-aged (MA N=290) and young-old (YO =286); high-worsening (16%), high-improving (20%) and low-stable (64%). The MA reported consistently higher levels of depressed mood at baseline for all classes. However, the YO high-improving did not improve as well as the MA high-improving class ($p<.001$), and the high-worsening rate of increase in depressed mood was significantly ($p<.01$) higher for the YO than the MA. The depressed mood level of the family caregiver at baseline was important in predicting class membership ($p<.01$), as well as differentially affecting the trajectories of patients within age group and latent class.

### AGE GROUP DIFFERENCES IN WELL-BEING AT CANCER RECURRENCE AND OVER TIME

M.M. Step, G. Kypriotakis, J.H. Rose, *Case Western Reserve University, Cleveland, Ohio*

Little is known about how patients adjust to a cancer recurrence. The purpose of this research is to assess the emotional adjustment of middle-aged (ages 40-60, n=182) and young-old (ages 61-80, n=138) recurrent and non-recurrent advanced cancer patients. A secondary analysis of newly diagnosed MA and YO patients revealed different adjustment trajectories at baseline, 3 and 6 month intervals. Latent growth curves fit to symptom distress, depression and functional status showed significant interactions between age group and recurrence status. MA recurrent patients reported consistently higher symptom distress (Wald statistic = 4.68, $p <.05$), depression (Wald statistic = 4.92, $p <.05$), and lower functional well being (Wald statistic = 5.11, $p <.05$) across time. Data suggest that recurrent cancer presents a unique challenge that persists for MA patients. To inform targeted interventions for MA patients with recurrent disease it may be beneficial to explore coping strategies among YO patients.

### UNPREDICTABLE RESUSCITATION PREFERENCES IN MIDDLE-AGED AND OLDER PATIENTS WITH ADVANCED LUNG CANCER

T. Phillips Towe[1,2], G. Kypriotakis[2,3], E. O'Toole[2,3], J.H. Rose[2,3], *1. Medicine-Hematology/Oncology, University Hospitals Case Medical Center, Cleveland, Ohio, 2. Case Western University, Cleveland, Ohio, 3. MetroHealth Medical Center, Cleveland, Ohio*

Studies have shown that preferences for life sustaining treatment are inconsistent over time with greater declines in choice for cardiopulmonary resuscitation (CPR) among elders. However, whether changes over time in preference for CPR vary by age is unknown. Latent class analysis was used to determine whether CPR preference trajectory within the first year after diagnosis of advanced lung cancer vary by age. Analysis of middle-aged (MA: ages 41-60 yrs, n=105) and older (ages 61-83, n=88) patients revealed distinct trajectories by age group. Among persons more likely to choose CPR after initial diagnosis, the likelihood of choosing CPR was sustained for MA patients and increased among older patients over time. Among persons less likely to choose CPR after initial diagnosis, the likelihood of choosing CPR declined over time with a lower likelihood of choosing CPR among older patients. Further exploration is needed to identify factors influencing persistent preferences for CPR.

### BEREAVEMENT IN CAREGIVERS OF YOUNG-OLD AND MIDDLE-AGED CANCER PATIENTS: WHOSE PROBLEMS MATTER?

L.E. Francis, K.F. Bowman, J.H. Rose, *Medicine, Case Western Reserve University, Cleveland, Ohio*

There are two models of late-stage cancer caregiver bereavement, that of relief and that of complicated grief. Both models appear to have validity under different conditions. The current study adds to this knowledge by underscoring the importance of patient life stage in predicting the caregiving and bereavement experience of late-stage cancer caregivers. Among MA patient caregivers, their own functional limitations (.034, p<.05), age (-.012, p<.05), depression (.017, p<.05), social support (.013,p<.05) and health burden (.053, p<.05) and family abandonment (.034,p<.05) exacerbated grief. For YO patient caregivers, their poor health (-.110, p<.05) and depression (.036, p<.05) complicated grief; but patients' practical (-.063, p<.05) and emotional (-.063, p<.05) problems decreased grief. We conclude that personal struggles among MA patient caregivers appear to increase their risk of complicated grief at bereavement. For YO patient caregivers, their own problems have little effect, but the personal problems of YO patients result in relief upon bereavement.

## SESSION 685 (POSTER)

## PERSONALITY

### THE TRANSITION INTO ASSISTED LIVING: DOES PERSONALITY PLAY A ROLE?

W.L. Mills[1], V. Molinari[2], C. McEvoy[1], J. Edwards[1], L. Hyer[3], D. Gammonley[4], L.M. Brown[2], *1. School of Aging Studies, University of South Florida, Tampa, Florida, 2. University of South Florida - Department of Aging and Mental Health Disparities, Tampa, Florida, 3. Mercer Medical School - Georgia Neurosurgical Institute, Macon, Georgia, 4. University of Central Florida - School of Social Work, Orlando, Florida*

It is expected that as the population continues to age, the demand for less restrictive long-term care options will increase, resulting in a greater number of older adults transitioning into assisted living (AL) settings. The new living environment may be very different from those previously experienced, thus placing new social and physical demands upon the new resident. This period of adjustment may be marked by psychological distress, stress, insecurity, exacerbated health problems, and a disconnect from the support of the social network. As adjustment into long-term care does not always proceed smoothly, it is imperative to identify factors related to these transition difficulties in order to ease the process. Previous studies of personality and adjustment to significant life events have shown that personality factors, particularly neuroticism and extraversion, play a role in predicting which individuals will adjust successfully and unsuccessfully following transitions. The purpose of this study was to investigate the relationship between personality factors and adjustment following the transition into AL using hierarchical multiple regression. Participants completed a questionnaire regarding their retrospective assessment of the transition experience. Personality was measured by the Big Five Inventory. Other measures included the Geriatric Depression Scale, Life Satisfaction Index Z, relative quality of life, adjustment, and feeling of home. Factor analysis was used to create a composite variable for adjustment. Hierarchical multiple regression analyses examine the relationship between the individual facets of personality (neuroticism, extraversion, openness, agreeableness, and conscientiousness) and adjustment to AL.

### APPLICATION OF THE RESILIENCE SCALE AMONG COMMUNITY-LIVING OLDER ADULTS IN JAPAN

F. Ishihara[1], M. Harigane[2], T. Ikeuchi[1], H. Osada[1], *1. J. F. Oberlin University Graduate School, Tokyo, Japan, 2. The Dia Foundation for Research on Ageing Societies, Tokyo, Japan*

Psychometric evaluation of the Resilience Scale (RS) has been examined in younger adults but not in older adults in Japan. The psychometric properties of the RS among community-living older adults were examined. Participants were 607 older adults over 60 years old (M = 66.4) enrolled in continuing education classes in an urban area. Measures included the RS (25 items), overall life satisfaction, subjective health, sex, and age. Exploratory factor analysis resulted in a 4-factor structure of resilience, named respectively as Perseverance (9 items including "When I'm in a difficult situation, I can usually find my way out of it"), Self-assurance (4 items including "I feel that I can handle many things at a time"), Self-possession (4 items including "I usually take things in stride"), and Purposefulness (3 items including "Keeping interested in things is important to me"). Five items were excluded. The internal reliabilities of the four factors ranged from .84 to .64. There were no sex differences in the RS total score and in the scores of four factors. The RS total score and the score of Self-possession was weakly correlated with age. All of the four factors of the RS were positively correlated with the overall life satisfaction and subjective health. Although the factor structure of the RS differed from the original, positive correlations of resilience with life satisfaction and subjective health found in the present study were consistent with those theoretically expected. Further studies are needed to address relationships between resilience and related factors in various populations.

### THE ROLE OF PERSONALITY IN PREDICTING UNSAFE DRIVER BEHAVIOR: COMPARISONS BETWEEN YOUNG AND OLDER ADULTS

J. Riendeau[1], M. Bedard[1,2,3], *1. Lakehead University, Thunder Bay, Ontario, Canada, 2. St. Joseph's Care Group, Thunder Bay, Ontario, Canada, 3. Northern Ontario School of Medicine, Thunder Bay, Ontario, Canada*

Drivers aged 16 to 19 years and 70 years or older are consistently overrepresented in crash statistics. Personality is consistently linked to dangerous driving among young drivers but little research has examined the role of personality among older drivers. Given the relationship between personality and driver safety among younger populations and the relative stability of personality throughout adulthood, it is important to examine whether personality traits may be related to unsafe driving in older adults. We recruited drivers under 65 years (young; n = 71) and drivers aged 65 years or older (old; n = 8; recruitment ongoing). A series of questionnaires measured personality traits and driving habits. Driving performance was measured during a 30-min simulated drive. Young drivers committed significantly more driving errors than did older drivers ($p < .01$). Among young drivers, some personality traits were related to driving performance (e.g., sensation seeking, $p = .01$). Conversely, among older drivers, driving performance was not related to any personality trait. On the basis of conceptual linkages and prior research, we expect that some personality traits will be more salient predictors of dangerous driving behavior among young drivers (e.g., sensation seeking) than among older drivers. If there are shared personality traits that predispose both young and older adults to risky driving, then appropriate countermeasures could be developed to reduce risks in both age cohorts.

### THE PHOTOGRAPHIC ACTIVITY DIARIES OF OLDER ADULTS: A REFLECTION OF EXTRAVERSION AND OPENNESS

S.L. Parks[1], S. Clancy Dollinger[1], J. Ashley[2], E. Hlaing[1], *1. Southern Illinois University - Carbondale, Carbondale, Illinois, 2. Centre for Neuroskills, Bakersfield, California*

Photographs have been used as a research tool within a variety of methodologies (e.g., autophotography) and populations (e.g., college students, homeless adults, immigrants) to explore areas of identity, self esteem and personality traits. The current study used photographs to examine personality and explore the lives of older adults. Forty-three older adults took photographs of their daily activities to complete a photographic diary over a period of four weeks. The photographs were coded based on a rating system developed specifically for this study to assess Extraversion and Openness. Older adults were administered the NEO Five-Factor Inventory (NEO-FFI), the Rand Health Survey (SF-36), the Geriatric Depression Scale (GDS) and the Mini Mental Status Exam (MMSE). Extraversion as measured by the NEO-FFI and the number of photographs designated as "Openness" (e.g., number of photographs of travel, number of photographs of group meals) were positively related in the overall sample. A positive relation between the Extraversion NEO-FFI score and the number of photos designated as indicators of "Extraversion" (e.g., number of photographs with others, number of photographs displaying positive emotions) was observed only in males. Extraversion was positively related to photos of Travel for females. Future studies should examine the facets of Extraversion (e.g., activity level and excitement seeking) and Openness (e.g., actions) and consider additional activity categories when coding photographs to better understand the relations between daily activities in older adults and personality traits.

## THE ASSOCIATION BETWEEN RESILIENCE AND DEPRESSION IN COMMUNITY-LIVING OLDER ADULTS IN JAPAN

T. Ikeuchi[1], M. Harigane[2], F. Ishihara[1], H. Osada[1], *1. J. F. Oberlin University Graduate School, Tokyo, Japan, 2. The Dia Foundation for Research on Ageing Societies, Tokyo, Japan*

This study examined the association between resilience and depression, as well as differences by sex in older adults enrolled in continuing education classes for seniors located in an urban area of Japan. The sample included 292 men and 264 women over 60 years old (mean age = 66.5, SD = 3.7). Participants completed questionnaires containing the Resilience Scale (RS) and the 15-item Geriatric Depression Scale (GDS). Pearson's correlation tests indicated that the total scores of the RS and the GDS were significantly correlated for men (r = -.54, p <.01) and women (r = -.36, p <.01). We performed a multiple regression analysis for men and women, controlling for four independent variables which were the RS's four factors. The four factors were named as: "Perseverance," "self-assurance," "self-possession," and "purposefulness." Dependent variable was the GDS score. The standardized regression coefficient indicated a significance in the perseverance of men (β = -.32, p <.01) and women (β = -.25, p <.01). There were marginally significant trends in the self-assurance of men (β = -.14, p <.10) and women (β = -.14, p <.10) and in the self-possession of men (β = -.12, p <.10). The self-possession of women and the purposefulness of men and women were not significant. We observed significant correlations between overall resilience and depression. However, the findings suggest that there are no significant associations between purposefulness of resilience and depression. There are sex differences in effect on the association with self-possession of resilience and depression.

## SUBJECTIVE STRESS AS A MEDIATOR OF THE EFFECT OF CONSCIENTIOUSNESS ON CARDIOVASCULAR SYMPTOMS

G.W. Edmonds[1], H. King[2], P.L. Hill[1], B.W. Roberts[1], *1. University of Illinois at Urbana Champaign, Champaign, Illinois, 2. The Pennsylvania State University, University Park, Pennsylvania*

Cardiovascular disease is a primary health concern in the United States. Recent work suggests that conscientiousness might protect against cardiovascular problems (Terracciano, Lockenhoff, Zonderman, Ferrucci & Costa, 2008). The current study investigated the role of conscientiousness on cardiovascular health, and examined whether perceived stress mediates this relationship. Moreover, we tested these relationships using the facets, or lower-order components that comprise conscientiousness. A large community sample (N = 2136) completed a survey of personality and health measures, including assessments of nine different conscientiousness facets (AB5C; Goldberg, 1999), self-reports of cardiovascular symptoms, and a measure of perceived stress (Cohen, Kamarck, & Mermelstein, 1983). We organize the nine facets provided by the AB5C into those associated with industriousness, order, and self-control. All of the nine facets of conscientiousness, with the exception of perfectionism, were negatively related to cardiovascular symptoms (r's ranged between .09 and .13; p's < .05). We tested for mediation using Preacher and Hayes' (2004) non-parametric bootstrapping method. This provided estimates of both direct and indirect effects. Of the eight facets of conscientiousness that were related to cardiovascular symptoms, six showed effects that were fully mediated by perceived stress. These were organization, purposefulness, dutifulness, orderliness, conscientiousness, and cautiousness. For the two remaining facets, efficiency and rationality, perceived stress partially mediated the relationship between conscientiousness and cardiovascular symptoms. These findings demonstrate that perceived stress mediates the relationship between conscientiousness and cardiovascular symptoms, and that facet level analyses provide differential prediction with respect to this important outcome.

## FACETS OF CONSCIENTIOUSNESS MODERATE AGE DIFFERENCES IN COGNITIVE PERFORMANCE

E.K. Graham, M. Lachman, *Psychology, Brandeis University, Waltham, Massachusetts*

The current study examined how facets of personality were related to cognition, and whether these associations varied by age. Literature suggests that while many personality traits are associated with domains of cognition, individual facets of personality may add additional explanation to these relationships. A sample of 115 participants aged 22 to 89 from the Boston area completed the Brief Test of Adult Cognition by Telephone (BTACT) and the NEO-FFI. As expected, there was no correlation between personality and age. Multiple Regression analyses were conducted on all cognitive subtests, using age and personality (traits and facets) as predictors, controlling for health, sex, and education. As expected, older adults showed lower cognitive scores than younger adults. On the trait level older adults high in conscientiousness showed lower verbal fluency than older adults low in conscientiousness. Furthermore, specific facets of conscientiousness are related to cognition, with variations by age. Age by conscientiousness facet interactions showed that older adults high in Deliberation were slowest, while individuals low in deliberation exhibited reaction times similar to young adults. Similarly, older adults high in Order were slower as compared to other older adults low in Order, but this was not the case for younger adults. This suggests that, while older adults are slower than young adults, this is not true for all older adults. Individuals with the characteristics of being ordered and deliberative during a task appear to be slowest in processing speed and reaction time, suggesting personality plays an important role in slowing with age.

## OLDER ADULTS IN COMMUNITY RESIDENCES AND ASSISTED LIVING: WELL-BEING AND PERSONALITY TRAITS

S. Clancy Dollinger, J. Sheffler, E. Hlaing, S.L. Parks, *Psychology, Southern Illinois University, Carbondale, Illinois*

The number of assisted living facilities for older adults has more than doubled over the last twenty years and has presented older adults an additional living option by providing assistance (e.g., health care) in a less restrictive environment than that found in a nursing home facility. The relations between psychological well-being and personality traits in 20 older adults living in their own homes and 20 older adults residing in an assisted living facility were examined. The older adults were administered the NEO-FFI (Costa & McCrae, 1992), the Rand Health

Survey (SF-36), the Geriatric Depression Scale (GDS), the Mini-Mental Status Exam (MMSE) and the Scales of Well-Being (Ryff, 1989). A semi-structured interview was also administered to explore the daily lives of the older adults. This method allowed the older adults to provide specific, detailed information including their preferred activities and hobbies. A positive relation between several of the variables (e.g., health, depression, activities, self-acceptance, autonomy, conscientiousness, and extraversion) was observed. Extraversion was positively related to health, and conscientiousness was positively related to environmental mastery in older adults living in their own home. Independence and having choices were critical factors that contributed to the well-being in the assisted living residents.

# SESSION 690 (PAPER)

## QUALITY OF LIFE INDICATORS

### MEASURING THE WELL-BEING OF OLDER POPULATIONS: A CROSS-NATIONAL ANALYSIS BASED ON A NEW COMPOSITE INDEX

T. Kaneda, M. Lee, K. Pollard, *Population Reference Bureau, Washington, District of Columbia*

Despite the current trend of global aging, there has been no standard set of indicators available to measure the overall well-being of older populations across countries. This lack of such a wellness index hampers efforts to evaluate policies and programs aimed at helping individuals age well. The absence of comparable cross-national indicators also inhibits countries' ability to learn from the experiences of one another. In this paper, we describe the Wellness Index of Older Populations, a summary measure designed to examine the well-being of older people across countries. The index consists of 13 indicators grouped into four domains that are considered to be critical determinants of a person's well-being in old age: material well-being, physical well-being, emotional well-being, and social connectedness and relationships. We created both the overall index and the sub-indices for each domain for three age groups—ages 50-64, ages 65-74, and age 75 and older. Our paper highlights the key findings from our analysis, in which we compare the well-being of older populations in the United States and 11 European countries. Preliminary results show that the United States scores the highest in overall level of well-being in all three age groups, followed by Sweden in the 50-64 age group and Switzerland in both the 65-74 and 75 and older groups. Spain and Austria are tied for the lowest rank in the 50-64 age group, while Spain ranks the lowest followed by Italy in the older age groups. Possible explanations for our findings are discussed in the paper.

### MATERIAL VS. PSYCHOSOCIAL EXPLANATIONS OF EDUCATIONAL DIFFERENCES IN OLD-AGE FUNCTIONING

D.A. Groffen[1,5], H. Bosma[1,5], F. Tan[4,5], M. van den Akker[3,5], G.I. Kempen[2,5], J. Van Eijk[1,5], *1. CAPHRI School for Public Health and Primary Care-Department of Social Medicine, Maastricht, Netherlands, 2. CAPHRI School for Public Health and Primary Care-Department of Health Care and Nursing Science, Maastricht, Netherlands, 3. CAPHRI School for Public Health and Primary Care-Department of General Practice, Maastricht, Netherlands, 4. CAPHRI School for Public Health and Primary Care-Department of Methodology and Statistics, Maastricht, Netherlands, 5. Maastricht University, Maastricht, Netherlands*

Background Taking into account our rapidly aging population, older people are of particular interest in studying health inequalities. The aim of the present study is to examine the relation between socioeconomic status and health-related functioning in older people and to find out how material factors (e.g. the lack of basic goods) and psychosocial factors (e.g. low self-efficacy) compare regarding the explanation of these socioeconomic differences. Methods Data came from 5,061 Dutch men and women aged 55 years and older who participated in the longitudinal SMILE study. Baseline data were collected between November 2002 and May 2004 and respondents were followed until May 2009 (follow-up range: 0 to 5 years). Multilevel analyses were used to study the association between educational level and longitudinal changes in physical and mental functioning (i.e. two subscales of the SF-36) and to study the relative contribution of material and psychosocial factors to this relation. Results Low educational level was associated with poor initial physical and mental functioning. However, no further widening of these gradients was found during follow-up. Material factors reduced the initial educational differences by an average of 29%, while psychosocial factors, mastery and self-efficacy in particular, reduced these differences by an average of 60%. Conclusion More than material factors, psychosocial factors, mastery and self-efficacy in particular, explained a large part of the educational differences in physical and mental functioning in older people. Further research is recommended to explore the amenability to change of characteristics that hamper people from taking control over their lives.

### DIFFERENTIAL INTERRELATIONS OF SUBJECTIVE INDICATORS OF QUALITY OF LIFE AND MEASURES OF LIFE SATISFACTION

M. Holzhausen[1], P. Martus[1], C. Scheidt-Nave[2], *1. Charité - Universitaetsmedizin Berlin, Berlin, Germany, 2. Robert Koch Institute, Berlin, Germany*

Different aspects of quality of life are related differentially to one another in old age. Especially, the relation between self-ratings of functional abilities on one hand and subjective well-being on the other has been a focus of interest. We examined various outcomes related to the overall construct 'quality of life' in a representative sample (N = 299) of women and men above 65 years of age. We looked at the interrelations of objective and subjective indicators of quality of life among each other, investigating the interdependence of subjective functioning and different measures of well-being. Specifically we focused on cross-sectional predictors of global life-satisfaction, derived from three different modes of assessment: a single-item question, the Satisfaction with Life Scale (SWLS; Diener et al., 1985), and the newly developed scale Life-Satisfaction in Old Age Multimorbidity (FLQM; Holzhausen et al., 2010) that takes into account those dimensions that are rated as individually relevant by respondents. Though assessing the same construct and being highly intercorrelated, regression modelling showed differential patterns of prediction across those three measures. In accord with models of subjective well-being and life-satisfaction, emotional components played a more prominent role in predicting overall life-satisfaction in the single-item assessment as compared to the more specific scales. In the latter, indicators of subjective functional impairment were more important predictors. Concluding, we stress a heightened awareness of the dependency of results in the field of life-satisfaction and quality of life research from the mode of assessment.

### EDUCATION, FUNCTIONAL LIMITATIONS, AND QUALITY OF LIFE AMONG OLDER ADULTS IN SOUTH KOREA

J. Lee[1], O. Lee[2], *1. The Sloan Center on Aging and Work, Boston College, Chestnut hill, Massachusetts, 2. Graduate Shool of Social Work, Boston College, Chestnut hill, Massachusetts*

Previous studies have shown a strong positive relationship between educational attainment and health of the elderly. The purpose of this study is to examine the predictors of functional limitations and quality of life based on educational attainment. The nationally representative sample (n=4,152) of adults aged 65 and older was drawn from the Wave I of the Korean Longitudinal Study on Aging (KLoSA) conducted in 2006. Hierarchical multiple regression analysis was undertaken to assess the unique explanatory contribution of socio-demographics, chronic health conditions, social engagement, cognition, and depression on functional limitations and life satisfaction. Two separate analyses were run to note differences between lower education (below the 6th grade) and higher education (above the 6th grade) groups. On the bivariate level, significant educational disparities exist in major study variables except for chronic illnesses. Yet, final models in hierarchical multiple regressions show cognition and depression greatly contribute to functional limitations and life satisfaction regardless of educational level. Friendships as opposed to support from children are significant predictors for both functional limitation and life satisfaction. While female gender and older age are predictors of functional limitations, marital status and welfare recipients are more likely related to life satisfaction. Implications for gerontological practice and policy are discussed in this paper.

## SESSION 700 (PAPER)

## RACE, GENDER AND HOSPICE USE

### PATTERNS OF HOSPICE USE AMONG ASIANS, AFRICAN AMERICANS, HISPANICS AND WHITES IN A CENTRAL FLORIDA

I.V. Carrion, N.S. Park, *Social Work, University of South Florida, Tampa, Florida*

Understanding hospice use patterns among different racial/ethnic groups is critical in providing culturally competent services. The purposes of this study were to examine characteristics of individuals in hospice by racial/ethnic groups and provide implications for practice. Method: The study included a total of 22,936 patients served by a hospice during a four-year period, 2002-2006 (Mage = 75.4, SD = 18.5). Of these, 80.6% were White, 9.6% were African-American, 9.3% were Hispanic and .5% were Asian American/Pacific Islanders. Chi-square tests and ANOVA were used to examine associations between characteristics of hospice users and race/ethnicity. Results: More females than males (51%-62% vs. 38%-50%) were represented. Older adults (ages 65 and older) were the most frequent users of hospice across four racial/ethnic groups. As for primary caregivers, spouse caregivers were most common for Whites (35%) and Asian/Pacific Islanders (36%), “other” (41%) caregivers for African Americans, and daughters (33%) for Hispanics. A majority of individuals had religious affiliation, but Asian/Pacific Islanders has the most diverse religious preferences including no religious affiliation (12%). Cancer was the primary diagnosis across the four groups; 60% of Asian/Pacific Islanders were diagnosed with cancer. Racial minorities were more likely to rely on Medicaid than Whites (10-70% vs. 4%). African Americans were most likely to be transferred from hospital (57%), whereas Whites had the highest proportions of people who were referred from assisted living/nursing homes (16% vs 7-10%). Lengths of services were comparable across groups. Implications: As the hospice settings become more racially/ethnically diverse, it is essential to attend to different circumstances and needs of racial/ethnic groups in providing care.

### PREFERENCE FOR HOSPICE AMONG OLDER ADULTS: THE ROLES OF UNCERTAINTY, SPIRITUALITY, GENDER AND RACE

J.G. Cagle, M.A. Lamantia, S.W. Williams, J. Pek, L. Edwards, *Institute on Aging, UNC Chapel Hill, Chapel Hill, North Carolina*

Previous research has identified that African American persons are less likely than Whites to receive hospice care at the end of life. To better understand the etiology of this disparity, this study used a secondary data analysis of the 2003 North Carolina End of Life survey (N=3,586) to explore how individual preferences for hospice are influenced by factors including: attitudes, behaviors, and demographic characteristics. The survey collected data from a random sample of AARP members across the state using a self-report questionnaire. Only respondents who indicated a familiarity with hospice were included in these analyses. Competing categorical models were fit to determine which factors predicted a preference for hospice care. In the first model, preference for hospice was constructed using “yes” and “no” responses, omitting responses of “unsure.” The second model included “yes” and “no or unsure” responses. In the first model, race was not a predictor of a preference for hospice, as an equal percentage (4%) of Black and White respondents did not want hospice care. When responses of “unsure” were included in the dependent variable, Black respondents were 2.2 times more likely than Whites to indicate no/unsure about a preference for hospice care ($p<.001$). In both models gender, the presence of an advance directive, and spirituality were consistent predictors of choosing hospice. Pre-existing uncertainty about preferences for end of life care may help explain differences in care at the end of life. Interaction effects, study limitations, and implications for future research will also be discussed.

### USE OF ROLE MODEL STORIES TO REDUCE BARRIERS TO HOSPICE AMONG AFRICAN AMERICANS

S. Enguidanos[1,2], A. Coulourides-Kogan[1], G. Taylor[2], *1. Davis School of Gerontology, University of Southern California, Los Angeles, California, 2. Partners in Care Foundation, San Fernando, California*

Numerous barriers to Hospice exist for African Americans and include lack of experience, knowledge, and misconceptions of hospice (Chung, Essex, & Samson, 2009; Born et al., 2003; Reese et al.,1999). The purpose of this study was to develop and test theoretically driven role model stories, real stories of other African Americans on Hospice, aimed at increasing knowledge and improving attitudes toward hospice to increase access to hospice care for seriously ill older African Americans. The role model brochure was developed from individual interviews with African Americans on hospice and their family members. Stories were developed based on theoretical concepts, including Social Learning Theory and Theory of Reasoned Action that have been used with other health behaviors. These stories incorporate the language of the storytellers and carry the cultural values and imagery of the intended audience. Methods. A pre post design was conducted to determine the impact of the role model stories in improving knowledge, attitudes, and intentions toward hospice. Seventy-one African Americans 62 and older with two or more chronic conditions were surveyed before and after reading the role model brochure. Results. Survey results demonstrated significant improvement in knowledge ($t= -5.7$, $p<.001$), with 63.6% scoring higher on knowledge at post test. Intentions to enroll family members and themselves also increased following review of the brochure ($p<.05$). Conclusion. Use of theoretically driven role models stories may improve access to Hospice among traditionally underserved populations.

### FACTORS INFLUENCING HOSPICE LENGTH OF STAY

M. Sengupta, E. Park-Lee, A. Bercovitz, R. Valverde, *CDC/NCHS, Hyattsville, Maryland*

Hospice care provides palliative services and recognizes patient autonomy, both of which studies have shown improve quality of life for dying patients. Studies have shown that hospice care needs to be provided for at least a month to realize the maximum benefits from care. Medicare pays a hospice provider a daily rate for each day that a patient receives care. Although studies have shown that the average length of stay has declined and a third of hospice patients die within the first 7 days of care, recently, the Medicare Payment Advisory Commission (MedPAC) identified an increase in the percent of patients with lengths of stay exceeding 180 days. MedPAC attributed this increase to a business model that boosts the profitability of the Medicare hospice benefit by maximizing length of stay. The purpose of this study is to identify individual and organizational factors that may influence hospice length of stay. Using the 2007 NHHCS, we examined which patient and provider characteristics are associated with length of stay in hospice. About 63% were in hospice for 30 or fewer days, 11% received care for 180 or more days, and 4% received care for over a year. Women had a longer average length of stay than men. The median length of stay was 20 days in proprietary agencies and 15 days in nonprofit agencies. Study findings could be used to inform policy decisions about factors that affect the cost of hospice care.

# SESSION 705 (PAPER)

## SERVING OTHERS AND EXPRESSING SPIRITUALITY

### CONSTRUCT VALIDITY OF MCDONALDS EXPRESSIONS OF SPIRITUALITY INVENTORY IN YOUNG AND OLD ADULTS

J. Fish, B. Hayslip, S. Clark, *Experimental Psychology, University of North Texas, Denton, Texas*

McDonald's Expression of Spirituality Inventory (ESI) assesses many aspects of spirituality. Confirmatory factor analysis yielded four factors for the ESI: F1- cognitive orientation toward spirituality, the importance of spirituality/religiosity, F2- experiential/phenomenological spirituality, assessing individuals' belief in having had divine experiences, F3- wellness, examining individuals' assessment of life events, and F4 - Paranormal Beliefs, reflecting individuals' belief in such phenomena (psychokinesis, ghosts) (Hayslip, et.al., 2010). These factor scores were subsequently correlated with a variety of measures of spirituality, religiosity, and well being in young adults (n=409, M = 21.3, SD = 1.77) and older adults (n=361, M = 73.16, SD = 8.21). These correlations were examined in light of the ESI's construct validity. In young adults, F1 was highly correlated ($p < .05$) with religious coping, a belief that God helped throughout life, personal spirituality, spirituality as a component of well being, cognitive religious commitment, and behavioral religious commitment. F3 correlated with somatization, obsessive compulsivity, interpersonal sensitivity, depression, anxiety, and negative affect. F2 and F4 were not highly correlated with any such measures. Among older adults, F1 correlated with a belief that God helped throughout life, lifetime religious social support, personal spirituality, spirituality as a component of well being, positive religious coping, and cognitive religious commitment. F3 correlated with somatization, obsessive compulsivity, interpersonal sensitivity, depression, anxiety, negative affect, and negative religious coping. Again, F2 and F4 did not correlate with any other measures. These data in part support the construct validity of the ESI in younger and older adults.

### AS WELLS RUN DRY: CLERGY, CONGREGATIONS AND SECULAR PROVIDERS COLLABORATE TO SERVE ELDERS

G.G. Glicksman, *Reconstructionist Rabbinical College, Wyncote, Pennsylvania*

The population of elders - increasing at a time of crisis in economic and other resources – challenges traditional providers to develop more effective models of support. By examining the ways that members of one religious tradition – Judaism – are reshaping their responses to these changing realities, the author hopes to lift up a model that holds promise for other groups. Rabbis and lay leaders of Jewish congregations face the challenges we all face, including diminishing economic, spiritual and personal resources amid increasing demands for support. There is greater geographic mobility, an ever-diminishing social safety net, and fewer familial and kin-like social supports. For many, the needs emerge in both the professional and the personal sphere, increasing the level of stress. Stress is even greater in congregations where members are dispersed over a wide geographic area, which is the case in many non-Orthodox Jewish congregations. One particularly exciting approach in the Jewish community is collaboration between synagogues and Jewish social service agencies. These partnerships promise increasing efficiency and effectiveness, enabling professionals and lay leaders to focus on their areas of expertise. They also encourage well-being through increased participation of elders and increased multi-generational involvement. This paper grows out of the author's survey of rabbis in non-Orthodox congregations, using computer-based questionnaires and follow-up in-depth interviews. The author is adding focused interviewing of rabbis, lay leaders and social workers who collaborate to serve elders and will highlight trends that suggest that this model is one that could be helpful for other faith communities.

### RELIGION AMONG OLD PEOPLE IN KOREA

J. Kim[1], M. Lee[2], Y. Lee[3], *1. NORC, Chicago, Illinois, 2. Chung-Ang University, Seoul, Republic of Korea, 3. Konkuk University, Seoul, Republic of Korea*

While religion is an important gerontological research area in the US, little attention is given to the religion of old people in Korea, where half of population is identified with either Buddhism or Christianity. Using the 1985, 1995, and 2005 Korean Census micro-data, and 2003-2008 Korean General Social Survey cumulative data (KGSS), we aim to provide basic information about religious affiliation, church/temple attendance, and subjective religiosity. The Korean Census from 1985 to 2005 shows that the non-religious population has decreased 12 percentage points from 50% to 38%, and that Catholicism has gained more adherents (7%) than Buddhism and Protestantism (4% respectively) in this period. At the same time, the traditional religions have lost 3 percentage points, dropping from 5% in 1985 to 2% in 2005. KGSS shows that 83% of Protestants, 76% of Catholics, and 7% of Buddhists attend church/temple once a week or more. Unlike religious participation, the difference between Buddhists and Christians is not relatively substantial in terms of subjective religiosity. For example 26% of Buddhists, 41% for Protestants, and 30% for Catholics said that their strength of religious belief is strong. Compared to younger people, old people have stronger religiosity across all religions. Given that old people become more religiously affiliated, have more frequent religious service attendance, and have stronger feelings of religiosity, religion merits greater attention to gerontologists in Korea.

### CARE, RECREATION AND AFFILIATION – OLDER VOLUNTARY WORKERS OF THE CHURCH OF FINLAND IN COSTA DEL SOL, SPAIN

J. Spannari, *University of Helsinki, Helsinki, Finland*

Positive relationship between voluntary work and personal well-being has been documented by multiple studies. But what meanings are attached to voluntary work in religious organizations by older volunteers themselves and what do they tell about the role of volunteering in a community of older adults? This paper focuses on the Finnish winterbird community in Costa del Sol, Spain - an exceptionally interesting community of older adults in its geographical distance but mental proximity to the country of provenance, and with religious organizations at the hub of social life. The study is based on texts and interviews of Finnish older adults residing in or frequently visiting the Spanish Costa del Sol and volunteering in Finnish religious organizations during their stay. Voluntary work is viewed 1) as care, recreation and a search for a role from the viewpoint of older volunteers and 2) as an intricate process of collective identity formation, affiliation and manifestation of values from the viewpoint of the community.

# SESSION 710 (SYMPOSIUM)

### STRETCHING THE BOUNDARIES OF THE AMBIVALENCE FRAMEWORK: NEW ARENAS FOR RESEARCH

Chair: *K. Hooker, HDFS, Oregon State University, Corvallis, Oregon*
Discussant: *T.M. Cooney, University of Missouri, Columbia, Missouri*

Intergenerational ambivalence is a thriving area of research that has enriched knowledge about family relationships in later life and has been shown to affect health and well-being. As the nuances of the intergenerational ambivalence framework are unpacked, it may provide a new lens through which to examine other relationships fraught with ambivalence. The papers in this symposium utilize the construct of ambivalence to examine caregiving relationships from interdisciplinary perspectives. In a longitudinal study of 121 families Blieszner, Roberto, and Savla examine ambivalence and biomarkers of stress among older married couples coping with mild cognitive impairment (MCI). Pearson and Duffy use case law and relevant research evidence to probe the legal implications and real-life consequences (e.g., loss of fortunes; jail time) of ambivalence in caregiver relationships. Williams and Qualls utilize a qualitative approach to determine the extent to which ambivalence may explain the low rates of future care planning among aging families of individuals with intellectual disabilities. Mejía and Hooker examine ambivalence in the context of discovering behavioral signatures, through sensor data and care documentation, in the creation of alternative late life family structures in long-term care. These papers all address ambivalence in relation to some aspect of caregiving in later life from the perspective of spousal partners, fiduciary agents and care receivers, parents who have dealt with dependence over their lifecourse, and families in long-term care settings. The discussant, Teresa Cooney, integrates the studies and will provide her perspective on ambivalence in caregiving and family relationships in later life.

### MILD COGNITIVE IMPAIRMENT AS A SOURCE OF AMBIVALENCE IN FAMILY RELATIONSHIPS

R. Blieszner, K.A. Roberto, J. Savla, *Human Development, Virginia Polytechnic Institute and State University, Blacksburg, Virginia*

Early memory loss among older adults diagnosed with mild cognitive impairment (MCI) challenges spousal and adult child-aging parent relationships because of their unique constellation of remaining strengths and emerging limitations in cognitive, affective, and behavioral functioning. Using a mixed-methods design incorporating structured scales and open-ended questions, we conducted in-depth interviews on 3 occasions over 3 years with multiple members of 121 families with an older adult diagnosed with MCI. For a subsample of 30 spouses, we also collected 7 days of daily diaries and assayed 4 days of salivary stress hormones. Analyses revealed that ambiguous symptoms and prognoses led to multiple dimensions of self-reported stress that was confirmed by the biomarkers. Participants reported numerous coping difficulties and perceived contradictions in relationships with the diagnosed person. Nevertheless, spouses and adult children remain committed to providing support to persons with MCI and exhibit ambivalence-associated coping strategies from which others can learn.

### LEGAL IMPLICATIONS OF AMBIVALENCE IN CAREGIVER RELATIONSHIPS

K.C. Pearson[1], J. Duffy[2], *1. Dickinson School of Law, Penn State University, Carlisle, Pennsylvania, 2. Queen's University Belfast, Belfast, United Kingdom*

"I trusted her" is what 98-year old Bertha said about her great-niece, who became her agent and caregiver. The great-niece said: "I did what she asked me to do, to the best of my ability." So, why was Bertha testifying against the great-niece on charges of theft and misuse of legal documents signed by Bertha? Analysis of this case suggests that both parties began with only a vague understanding of what their relationship might entail, "assisted" by an attorney who asked few, if any, relevant questions. Failure to recognize that caregiver relationships are fraught with the potential for deep ambivalence can have tragic results. In this instance, Bertha lost over $800,000 — and the great-niece went to jail. The authors use an American case history, relevant research evidence and a case decided by the Supreme Court of Ireland to probe the legal implications of ambivalence in caregiver relationships.

### AMBIVALENCE ABOUT PLANNING FOR FUTURE CARE TRANSITIONS IN AGING FAMILIES OF INDIVIDUALS WITH INTELLECTUAL DISABILITIES

A.A. Williams[1,2], S.H. Qualls[1,2], *1. Psychology Department, University of Colorado at Colorado Springs, Colorado Springs, Colorado, 2. Gerontology Center, Colorado Springs, Colorado*

Low rates of future planning in highly dedicated families suggest that ambivalence may be a powerful factor in deterring planning processes. The present study investigated interpersonal as well as intrapersonal role ambivalence that serves as a barrier to future planning. Older parents of individuals with intellectual disabilities (ID) typically have in mind plans for future transitions in care and advocacy structures when they can no longer serve those roles, yet they engage in very low rates of planning. A qualitative study conducted using a phenomenological framework engaged 33 members from 8 families in in-depth interviews. Ambivalence was an overarching theme across members of all families, with variations organized by family role. This project suggested that parents, siblings, and care systems each experience intrapersonal ambivalence about the process of planning for the post-parental future of adults with ID, and their interpersonal interactions often build rather than reduce ambivalence.

### EXPLORING THE BEHAVIORAL SIGNATURE OF HOME AND FAMILY IN A LONG-TERM CARE SETTING

S. Mejia, K. Hooker, *Human Development and Family Sciences, Oregon State University, Corvallis, Oregon*

Ambivalence is ubiquitous across resident, staff, and family members' interactions in long-term care. The formation of alternative family structures in long-term care environments may reconcile these feelings by fostering a sense of place and home among participants, as they transition into new roles and expectations. Our study explores how these alternative family structures are co-created by residents, staff, and family members. We used unobtrusively collected sensor data coupled with care documentation from two contrasting houses at Oatfield Estates, a residential care facility in Oregon. Oatfield Estates is known for its use of smart technology to support quality of life among residents, and dedication to aging in place for residents with diverse physical and cognitive capabilities. We examined characteristics and patterns of behavior among residents, caregivers, family members, and management at Oatfield Estates to explore the behavioral signature of an environment that supports and nurtures a sense of home and family.

## SESSION 715 (POSTER)

## TECHNOLOGY: DEVICES AND USERS

### VOICING UNCERTAINTIES ABOUT THE BEST DEVICE TO HAVE FOR REACHING HELP QUICKLY: THE EXPERIENCE OF AN OLDER HOMEBOUND WOMAN WHO HAD TRIED MULTIPLE DEVICES

E.J. Porter, *University of Missouri, Columbia, Missouri*

More community-dwelling older persons are adopting devices for reaching help quickly (RHQ), many by subscribing to a personal emergency response system (PERS). Most related research has focused on device effectiveness and client satisfaction. The few qualitative studies have pertained to considering PERS subscription, adjusting to having a PERS, or intentions about using one's PERS. Most PERS subscribers continue subscribing. Little is known about experiences of older women who cease PERS subscription, opting for another RHQ device. Data for this case study were obtained during a descriptive phenomenological study of the experience of RHQ with 40 women (aged 85-98). One woman, who had ceased a PERS subscription and installed a security system, voiced uncertainties about that decision during the 18-month study. She experienced falls, acute health problems, and household emergencies – situations that influenced her contemplations as a person knowledgeable of multiple options for RHQ. Facets of life-world associated with her experience of RHQ were described, including: noting that I could change back to the PERS if I had to and predicting that I will go back to the PERS when the security contract expires. Her struggle became a chronic stressor, influencing her eventual decision to break the security contract and re-subscribe to PERS. As options for RHQ devices increase, increasing numbers of older persons could become serial users of various devices and experience the stressor of wondering if they would be "better off" with a different device. Researchers should describe personal and societal implications of this newly identified chronic stressor.

### USABILITY TESTING OF WEB-BASED MULTIMEDIA HEALTH TUTORIALS BY OLDER ADULTS

B. Xie, I. Watkins, N. Thakker, *College of Information Studies, University of Maryland, College Park, Maryland*

Three consecutive sessions of usability testing of three Web-based multimedia health tutorials – MedlinePlus Surgery Videos and MedlinePlus Interactive Tutorials both maintained by the National Institutes of Health, and EdHeads Virtual Surgery by a non-profit organization – with 10 older adults was conducted in February-March of 2010. The aim of the study was to compare the senior-friendliness of these multimedia health tutorials and to generate preliminary data on older adults' use of Web-based multimedia features. Data were collected from interviews, surveys, and observation. Major findings are: 1) Interactivity (e.g., built-in hands-on practice, quiz) can be useful but needs to be the right amount (not too little, not too much) and the right type (not too simple, not too complicated) for the right audience; 2) a clickable element that entails both a symbol and a word is more easily recognizable by older adults than that with a symbol alone; and 3) showing "the big picture," including showing both how a specific body part is in relation to the whole human body and where the user is located within the broader framework of the tutorial, is important for the user to understand and follow the tutorial. Overall, the MedlinePlus Interactive Tutorial site was the most popular, followed by EdHeads. The MedlinePlus Surgery Video site, which has little interactivity, presents the most difficult clickable elements, and shows no "big picture," was the least popular. Based on the test findings, we recommend design and training interventions to facilitate older adults' use of Web-based multimedia health tutorials.

### TECHNOLOGY USE IN LATER ADULTHOOD: THE ROLE OF ATTITUDES AND COGNITIVE ABILITIES

B. Williger, F.R. Lang, *Institute of Psychogerontology, Erlangen, Germany*

Successful aging highly depends on the functional allocation of the physical, cognitive, social, and emotional resources which are partially challenged by age-related losses. Recent studies suggest that these resources do also determine the use of technical devices in later adulthood. Accordingly, lower or reduced cognitive mechanics (e. g. information processing, spatial abilities) as well as technology anxiety seem to be associated with less frequent use of new technologies. In addition, cognitive pragmatics such as general knowledge or reading comprehension were found to predict the breadth and intensity of computer experience. We were able to replicate and extend these findings in an ongoing longitudinal study with 74 older adults. The participants were asked to regularly test and evaluate technical products and prototypes within the course of twelve months. First wave results show that the mechanics of intellectual capabilities constitute important resources when deciding whether to use new technologies in later adulthood. Furthermore, older adults' attitudes towards technology were found to strongly influence their usage behavior. Accordingly, participants with high technical openness and less distrust towards technology reported more frequent use of modern technical devices. The effects remain stable when controlling for age, education and personality. Results confirm theoretical considerations that fluid cognitive abilities as well as positive and negative attitudes towards technology predict the use of technical innovations among older adults. Follow up data of the one-year longitudinal study will help to understand which role technical expertise as a form of crystallized intelligence play when deciding on technology use.

### THE IMPACT OF AN INTERGENERATIONAL VIDEO GAME EXPERIENCE ON YOUNG ADULT'S PERCEPTIONS OF AGING AND OLDER ADULTS

M.M. Wood, K. Reis, M. Freitag, B. Davis, M. Sloan, S.J. Kohn, *Psychology, Valdosta State University, Valdosta, Georgia*

A key strategy for enhancing both undergraduate teaching and learning in gerontology and aging psychology courses often involves selective use of innovative intergenerational curricular activities. This study addresses the results of a second wave of a long-term project involving 124 undergraduate students (M-age=22.42) and 21 community-dwelling older members (M-age=74.16) of a campus-wide continuing education program. Our primary goal was to gather participants from different generations in a relaxed, informal setting to share a mutual recreational experience (playing Nintendo's Wii video game system) to promote intergenerational communication, while reducing ageist stereotypes. The undergraduate students were administered objective and subjective measures as pre-tests at beginning of the academic year (T1) prior to engaging in the 2-3 times/week Wii-sessions with the older adults. Using a repeated measures design, we then administered the measures again as a post-test at the conclusion of the academic year (T2). Thirty-four students did not attend any Wii sessions, but did complete the pre- and post-test measures; and thus served as a control group that was limited to learning experiences from course materials and assignments. Paired-sample T-tests for T2 showed significant mean value changes from T1 for the Fraboni Ageism Subscales. A series of ANOVAS also revealed significantly greater reduction in ageist beliefs for the students participating in the Wii-sessions compared to the control-group (which did not participate). These results are important because they suggest that the Wii experience may have heightened students' gerontological learning experiences above and beyond traditional scholastic outcomes limited to the domain of the classroom.

### THE EMOTIONAL RESPONSES OF OLDER ADULTS TO NEW TECHNOLOGIES

K. Kim, W. Chodko-Zajko, A. Schwingel, L. Malavasi, *University of Illinois, Urbana, Illinois*

Understanding the perceptions and emotions of older adults when they encounter new technologies is important. If the benefits of using new technologies are perceived to be less worthwhile than the difficulties experienced while using them, older adults might decline to adopt otherwise useful tools. This study is designed to assess older adults responses to several examples of novel and familiar technological devices. The familiar technological devices will be TV remote controls and the novel devices will be pedometers (also known as "step counters"). For both the familiar and novel devices, older adults will be invited to inspect an "easy-to-use" and a "complex" version of a commercially available product and provide information about how likely they would be to adopt the new product in their everyday lives. Using a simple mixed method research design, four older adults (2 men; 2 women) will be asked to rate each product using a simple pencil and paper instrument known as Product Personality Profiling (PPP). PPP is frequently used by industrial designers to assess consumer reactions to new products. In addition, each participant will be invited to participate in a 60-90 minute focus group in which they will be given an opportunity to comment on their reaction to each of the four devices. The goal of the study is to increase our understanding of how older adults feel when they are asked to use new physical activity promoting technology.

## BRIDGING THE GENERATIONS: COMPUTER USE AMONG OLDER ADULTS IN A SENIOR HOUSING SETTING

A.D. Peeples[1,2], A. Frankowski[2], M. Kessler[2], A. Handers[2], *1. Doctoral Program in Gerontology, UMBC/UMB, Baltimore, Maryland, 2. Center for Aging Studies, UMBC, Baltimore, Maryland*

Motivated older adults are rapidly overcoming the digital divide in order to improve their access to computer networks, maintain contact with family, and pursue available information on health and dating. To understand this transition, ethnographic research was conducted with a low income, racially and ethnically mixed population of older adults residing in an independent living senior housing community located in a metropolitan area in a mid-Atlantic state. Four researchers over a two year period met bi-monthly with residents for a series of informal, individualized computer and internet skills tutoring sessions. A significant number of these residents suffer from chronic illness (e.g., stroke, Parkinson's, arthritis, diabetes-related amputations, poor eyesight, mild dementia), the manifestations of which currently hinder computer use. This poster provides data on two focal questions in our study: 1) what adjustments in computer design and 2) what changes in social attitudes are needed to enable older adults learn and utilize computer technology with ease and confidence? We examine the effects of gender, age, social class, health status, and former occupational patterns of research participants on computer use, and determine what residents most need and want from computers in their everyday lives.

## DETERMINANTS OF TELEHOME CARE NEEDS WITH CORONARY ARTERY DISEASE IN THE CHINESE COMMUNITY ELDERLY

M. Lee[1], P. Chen[2], M. Lee[3], *1. Long-Term Care, National Taipei College of Nursing, Taipei, Taiwan, 2. National Taipei College of Nursing, Taipei, Taiwan, 3. National Taipei College of Nursing, Taipei, Taiwan*

Background: Coronary artery disease (CAD) is a life-threatening disease in the elderly. Due to the limitations of medical resource and costs, the combination of technology and care services in home care becomes an important issue. Any innovative care services should be tested through an understanding of the feelings of customers to truly reflect the value of the services. Thus, the purposes of this study are to investigate the needs of telehome care in the community elderly with CAD. Method: A descriptive correlation study, with 120 CAD elderly participants who were discharged from three medical institutions within a year was recruited for the study purposes. Uncertainly, social support, personal and disease characteristics, and telehome care needs of the study participants were explored in this study. Results: The results demonstrated that the score of telehome care needs was skewly distributed to the right, and the mean score was relatively low. In the subdimension of telehome care needs, the results also showed that the needs of emergency assistance was the highest, and the need of role adjustment and social interaction was the lowest. Subjects with the highest scores of telehomecare needs were married, well educated, had more co-morbidities, functional limitations, and higher scores in social support. By using logistical regression analysis, co-morbidities and social support were the only two strongest predictors in telehome care needs. Conclusion: According to this study results, the suggestions were proposed in both practice and design for tele-home care among the community elderly CAD patients. Keywords:Telehome care needs, coronary artery disease, elderly

## PLUGGED IN, PUT DOWN: IMAGES AND RESPONSES TO IMAGES OF OLDER ADULTS ON SOCIAL NETWORKING SITES

C. Douglass[1], N. Dougen[2], *1. Public Health, Northern Illinois University, DeKalb, Illinois, 2. Clinton Rosette Middle School, DeKalb, Illinois*

An intergenerational research team, consisting of a middle-school student and his gerontologist parent, undertook this study of images and responses to images of older adults on social networking sites (SNS) including YouTube and Google Videos. The purpose of the study was to determine if images of older adults were primarily positive or negative and, equally important, what types of responses to these images were posted by SNS participants. Past research has shown that older adults are frequently portrayed negatively in the media including television (Harwood, 2000) and films (Bazzani, 1997). The researchers hypothesized that a similar pattern would exist for images of older adults on SNS. This hypothesis was confirmed. The researchers examined the responses to these images to better understand how participants of SNS experienced the images. This second area of research was exploratory, no predetermined hypotheses were tested. Using a grounded theory approach, analysis was conducted by the two researchers resulting in overarching themes describing both the images and responses to the images. Three primary themes emerged from the images: 1) older adult as foolish, 2) older adult as victims, and 3) older adults as superhuman (portrayed initially as frail, then transforming with superhuman powers). The overwhelming response to all three of these image types was humor. Most people indicated that they found these images amusing to view. Two additional themes emerged from the posted responses: 1) pity was seen in relation to older adults as victims and 2) praise was seen in relation to older adults as superhuman.

## ELECTRONIC MEDICAL RECORD (EMR) USE IN HOME HEALTH AND HOSPICE CARE AGENCIES

A. Bercovitz, M. Sengupta, P. Jamison, *National Center for Health Statistics, Hyattsville, Maryland*

EMRs are proposed as mechanisms to improve quality and cut costs, including improvement of coordination of care through electronic exchange of information. Nationally representative data on EMR use among providers of home health and hospice care are limited. Using data from the National Center for Health Statistics' 2007 National Home and Hospice Care Survey, we examined EMR use among home health and hospice care providers. Forty-one percent of providers had EMRs, and an additional 15% planned to have EMRs within the next year. Among providers with EMRs 98% had a component for recording patient demographics, 82% had a component for clinical notes, and over half had clinical decision support systems or computerized physician order entry, but less than 10% had the capability to share records with other health care organizations. Larger providers of only home health care or only hospice care, non-profit and government providers, providers owned by or operated with hospitals or other types of health care organizations, and providers with contracts with skilled nursing facilities were more likely to have EMRs. Since less than half of providers of home health and hospice care have EMRs, their use would have to increase significantly for providers to be able to exchange information electronically.

## EFFECTS OF TRAINING AND EXPERIENCE ON COMPUTER RELATED SELF-EFFICACY AND ANXIETY IN OLDER ADULTS

K. Wild, N.C. Mattek, H. Jimison, J. Kaye, *Oregon Health & Science University, Portland, Oregon*

According to U.S. Census data, the percent of households of individuals 65 years and older that have Internet access increased from 29% in 2003 to 53% in 2009. The rapid expansion of computer and Internet access in this age group coincides with recent research that puts to rest the misconception of older adults as technophobes. However, much of that research is based on attitudes towards hypothetical uses of technology rather than eliciting opinions based on personal experience. This study describes differences in computer related self-efficacy and anxiety in subgroups of older adults, and changes in those measures following exposure to a systematic training program and subsequent computer use. Participants were subjects in the Intelligent Systems for

Assessment of Aging Changes Study (ISAAC) carried out by the Oregon Center for Aging and Technology. The training program, consisting of six one-hour sessions, was designed to help participants achieve computer proficiency, as defined by the ability to turn on and off the computer, launch programs from the desktop, send and receive Email, and navigate the World Wide Web. Participants (n=141; mean age = 84, 73% female) were administered two questionnaires prior to training and again one year later, related to computer self-efficacy and anxiety. Baseline comparisons by age and gender, but not cognitive status (MCI vs. Normal), yielded significant differences in anxiety and confidence related to specific aspects of computer use. At one-year follow-up, participants reported less anxiety and greater confidence; however the benefits of training and exposure varied by group and task.

### SELF-RATED HEALTH, PERCEIVED CONTROL AND DEPRESSION AMONG MIDDLE-AGED AND OLDER USERS OF ELECTRONIC CANCER SUPPORT GROUPS

G. Seckin, T. Turner, *University of Maryland, Baltimore County, Baltimore, Maryland*

Eighty-two percent of the Americans aged 50 to 64 and 66% of those aged 65 and older use web resources to obtain medical and health information. This study examined the associations between socio-demographic variables, self-rated health, perceived control, and depression among a convenience sample of cancer patients (M age=50.23, S.D. =10.91) who were participants in mailing lists of electronic cancer support groups (n=350). Direct associations were modeled between self-rated health (conceptualized as perceived distress with treatments and satisfaction with health status), perceived control over health, and depressive symptoms. Analyses indicated that younger age (Slope = -.005; B= -.09, p =.05), higher perceived distress with treatments (Slope = .15; B= .22, p =.001), lower satisfaction with health status (Slope = -.24; B= -.39, p =.001) and less perceived control over health (Slope = .08; B= .13, p =.004) were significantly associated with higher levels of depressive symptoms. Multiple regression analyses also indicated importance of open communication between providers and patients who use electronic information sources, as patients' comfort level in bringing internet information to attention of medical professionals was associated with less depressive symptoms (Slope = -.08; B= -.12, p =.01). Interestingly, frequency of discussion was found to be significantly associated with depression (Slope = .08; B= .10, p =.05). These findings suggest that patients' increased need to discuss information obtained from online cancer groups may be indicative of higher levels of psychological distress, and patients feeling comfortable in communicating with their doctors emerges as a significant variable to enhance psychological well-being when coping with a chronic illness.

### ARE HEALTH ANSWERS ONLINE FOR OLDER ADULTS?

M. Cresci[1], T. Templin[1], R. Morrell[2], *1. Wayne State University Insitute of Gerontology and College of Nursing, Detroit, MI, 2. Human Resources Research Organization, Alexandria, Virginia*

The Internet has the potential for engaging older adults in managing their health by providing greater access to health information and services. Yet little is known about their interest in using the Internet as a health management tool. This study explored interest among community dwelling older adults in learning to use the internet as a health management tool. Survey data collected at the 9th Annual Art of Aging Successfully (n=187) were analyzed. Prevalence of Internet use was 54.6% with 73.2% accessing the Internet from home. Mean age was 69.89 (SD=8.542, range 50-97); 95.7% were female, 55.6% were African American, 70% had greater than a high school education and 60.4% had income > $20,000. Findings indicated that 41.2% of those who used the internet used it for health information with 43.9% seeking information about specific diseases and 36.4%, specific treatments. Use of the internet for health information was significantly related to age, education, and income ($p < .05$) but not to race/ethnicity. In logistic regression only age remained significant, with probability or internet use for health information ranging from 77% (50-60 yr old) to 19% (70-80 yr. old). Findings also indicate an interest in using a secure, private, safe, elder friendly health web portal to store and access: personal health information (41.2%); selected health websites (47.6%); current medications (44.3%); health benefit resources (49.2%); and health care providers (48.7%). Future studies are needed to explore health outcomes related to the use of an elder friendly health web portal.

## SESSION 720 (SYMPOSIUM)

### THE INTERPLAY OF PSYCHOSOCIAL RESOURCES AND HEALTH IN ADULTHOOD AND OLD AGE

Chair: *F.J. Infurna, Penn State University, State College, Pennsylvania*
Co-Chair: *D. Gerstorf, Penn State University, State College, Pennsylvania*
Discussant: *J. Heckhausen, University of California, Irvine, Irvine, California*

Lifespan research has long been interested in examining structural relations between domains of functioning. The major objective of this symposium is to bring together a collection of empirical studies using a multitude of different approaches to investigate how psychosocial resources and health shape key outcomes of adult development and aging. Polito and Lachman report from an experimental study that a personality trait (conscientiousness) was protective against increases in physiological markers of stress (cortisol) to a laboratory stressor and highlight that age moderates this relationship. Bergeman and Montpetit apply dynamic systems modeling to daily diary data and examine day-to-day associations between stress and negative affect. Their results indicate that individuals exhibiting less coupling between stress and negative affect are more stress resistant and protected from adversity. Carsten Wrosch uses a longitudinal panel study spanning 4 years to illustrate that longer sleep duration is protective of a key physiological mechanism of functioning (cortisol output), independent of sociodemographics and central health-related variables. Infurna and colleagues target long-term antecedents, correlates, and outcomes of perceived control. They report that control predicts subsequent risks for disability and mortality and in turn is predicted by levels and changes in social participation, life satisfaction, and health. The discussion by Jutta Heckhausen will integrate the four papers and highlight how various types of integrative research on the interplay between psychosocial resources and health will further our understanding of adult development and aging.

### CONSCIENTIOUSNESS AND CORTISOL: PERSONALITY AND AGE DIFFERENCES IN HEALTHY HPA AXIS REGULATION

M.J. Polito, M. Lachman, *Psychology Department, Brandeis University, Waltham, Massachusetts*

Cortisol is a key hormonal marker of stress in the hypothalamic-pituitary-adrenal (HPA) axis, and some profiles have been identified as indicators of healthy regulation, both in the naturally occurring diurnal cycle and in the laboratory. In a sample of adults aged 22 to 89, we examined whether HPA axis regulation was associated with age, education, sex, and conscientiousness, a trait previously linked to health and longevity. We found that high conscientiousness predicted healthy cortisol patterns, including a larger awakening response, steeper daily decline, and less reactivity and quicker recovery to a laboratory stressor. Age moderated these relationships, such that the beneficial effects of conscientiousness were larger with increasing age for the awakening response but smaller with age for the daily decline. The results add to the growing body of work linking conscientiousness and health by considering the link with cortisol, a major stress biomarker.

### STRESS RESISTANCE AND STRESS RECOVERY ON HEALTH: NOTRE DAME STUDY OF HEALTH AND WELL-BEING (NDHWB)

C.S. Bergeman[1], M.A. Montpetit[2], *1. University of Notre Dame, Notre Dame, Indiana, 2. Illinois Wesleyan University, Normal, Illinois*

Resilience is the ability to encounter exacerbations in daily stress without a concomitant acceleration in negative affect (NA; stress resistance), or to damp stress-induced NA more quickly (stress recovery). The study used 56 days of self-report data (N=700) from the NDHWB. Results from dynamical systems analysis using a coupled linear oscillator model indicated significant frequency ($\eta$=.35±.00), which represents the oscillation of NA around one's equilibrium, and significant damping ($\zeta$=-.03±.01), which is conceptualized to represent stress recovery. Individuals who return to equilibrium more quickly are thought to be hardier or more resilient. Acceleration in Stress was coupled with acceleration in NA ($\gamma$=.21±.01); loosely interpreted, the conception of stress reactivity represents the emotional sensitivity of an individual to the impact of daily stressors. Exhibiting less coupling represents stress resistance, which protects one from adversity. These components are in turn used to predict health outcomes in mid and later life.

### SLEEP DURATION BUFFERS DIURNAL CORTISOL INCREASES IN OLDER ADULTHOOD

C. Wrosch, *Psychology, Concordia University, Montreal, Quebec, Canada*

This study examined associations between reports of sleep duration and diurnal cortisol secretion in older adulthood. It was hypothesized that long sleep would protect older adults against increases in diurnal cortisol secretion over time. The hypotheses were tested using three waves of data from a 4-year longitudinal study involving 160 older adults. Results from growth curve analyses and cross-lagged panel analyses suggest that high levels and increases in sleep duration were associated with fewer increases in subsequent levels of diurnal cortisol secretion. Cortisol secretion, by contrast, was not associated with changes in sleep duration. The results were independent from baseline levels of sociodemographic characteristics (age, sex, and SES) and health-related variables (chronic disease, functional disability, physical symptoms, medication usage, BMI, and smoking). The findings suggest that longer sleep duration can protect older adults from exhibiting increases in cortisol output over time. Implications for theories of successful aging are discussed.

### LONG-TERM ANTECEDENTS AND OUTCOMES OF PERCEIVED CONTROL: LINKS TO SOCIAL PARTICIPATION, LIFE SATISFACTION, HEALTH, AND MORTALITY ACROSS ADULTHOOD AND OLD AGE

F.J. Infurna[1], D. Gerstorf[1,2,3], N. Ram[1,2,3], J. Schupp[3,4], G.G. Wagner[2,3,5], *1. Penn State University, State College, Pennsylvania, 2. Max Planck Institute for Human Development, Berlin, Germany, 3. DIW Berlin (German Institute for Economic Research), Berlin, Germany, 4. Free University, Berlin, Germany, 5. Berlin University of Technology, Berlin, Germany*

Perceived control plays an important role in shaping development throughout adulthood and old age. Using data from the German Socioeconomic Panel study, we explore long-term outcomes and antecedents of perceived control and examine if associations differ across adulthood. Targeting outcomes of control, survival analyses revealed that perceived control predicted 14-year hazard rates for disability and mortality. The effect for mortality, but not for disability, was independent of sociodemographic and psychosocial factors and more pronounced in older ages. Targeting antecedents and correlates of control, findings indicated that higher levels of social participation, life satisfaction, and self-rated health, in addition to more positive changes in social participation over the preceding 10 years were each predictive of perceived control. Limited support was found for age differential associations. We discuss that perceived control is embedded in various systems of influence and how these may or may not differ across adulthood and old age.

## SESSION 725 (SYMPOSIUM)

### AGING, ALCOHOL, AND ADDICTIONS: INTERDISCIPLINARY SOLUTIONS TO SCREENING AND INTERVENTION FOR OLDER ADULTS IN TRANSITION

Chair: *J. Culberson, Baylor College of Medicine, Houston, Texas*
Discussant: *K. Barry, University of Michigan, Ann Arbor, Michigan*

The Aging, Alcohol, and Addictions Informal Interest Group has cultivated novel interdisciplinary approaches to the emerging clinical entities of alcohol and prescription drug misuse in older adults. Presenters will demonstrate that transitions experienced by older adults during their lifetime have a significant effect on the development of hazardous patterns of alcohol and prescription drug use, and create specific challenges for screening and intervention. The symposium will include a presentation of the Healthy Living as You Age Study. This is a randomized trial of an intervention that includes personal feedback, advice from a physician, and health educator counseling to reduce at-risk drinking among older adults in a primary care setting. A second presentation will describe prescribing patterns for opioid analgesics in the management of persistent pain in an ambulatory geriatric primary care clinic. Results will be compared to evidence-based guidelines recently updated by the American Geriatrics Society for the treatment of persistent non-malignant pain. Another presentation will demonstrate the use of factor analysis to identify age-appropriate subscales and scale items for developing a short version of the Pain Medication Questionnaire. This work is essential in the development of instruments to assess potential opioid medication misuse in an aging population. Finally, results will be presented from a program providing referral-based outpatient age-specific treatment for addictions in older adults. The presentation will highlight treatment approaches and outcomes for late life addictions, and examine the unique needs of the individual with substance use disorders in later life.

### REDUCING AT-RISK DRINKING AMONG OLDER ADULTS IN PRIMARY CARE: THE HEALTHY LIVING AS YOU AGE STUDY

A.A. Moore[1], F. Blow[2], M. Hoffing[3], S. Welgreen[4], L. Tang[1], K. Barry[2], *1. UCLA, Los Angeles, California, 2. University of Michigan, Ann Arbor, Michigan, 3. Desert Oasis Healthcare, Palm Springs, California, 4. Kaiser Permanente, Panorama City, California*

Purpose: We conducted a randomized trial testing the efficacy of a primary-care based intervention to reduce at-risk drinking among older adults. Methods: Control group participants (n=321) got a booklet on general health behaviors and intervention group participants (n=310) got personalized feedback, a booklet on alcohol and aging, advice from their physician and up to three health educator counseling calls. Results: At baseline, 73% of participants were at-risk due to alcohol-medication combinations; At 12 months, alcohol consumption was less in the intervention compared to the control group (9.27 vs. 10.71 drinks per week; and 0.29 vs. 0.52, heavy drinking days per week (both p<0.5). At 12 months, 53.87% of intervention vs. 60.38% of controls (OR 0.77; 95% CI 0.54 to 1.11) were at-risk drinkers. Conclusions: The intervention among older at-risk drinkers in primary care reduces amount of drinking and between group differences in drinking outcomes largely persist at 12 months.

### OPIOID ANALGESIC USE IN ELDERLY AMBULATORY VETERANS

A. Gomez, J. Culberson, N.J. Rianon, *Baylor College of Medicine, Houston, Texas*

The American Geriatrics Society (AGS) has established evidence-based guidelines for the management of persistent pain, which includes the appropriate use of opioid analgesics. We performed a chart review of ambulatory patients seen in the Houston MEDVAMC Geriatric clinic during October 2009. Fifty-three received either an initial or renewed analgesic prescription. Data was gathered on demographics, co-morbidities, analgesic use, and pain level. Descriptive statistics and bivariate analysis were performed. The prevalence of opioid analgesic use was 43% and only 30% of those receiving opioids were prescribed these on a scheduled basis. About 70% of veterans receiving opioids reported moderate to severe pain, however, among those 2/3rd (69%) were prescribed opioids on an "as-needed" basis. We conclude that opioid analgesics were commonly prescribed to elderly ambulatory patients; however, most veterans who reported moderate to severe pain received opioids as-needed as opposed to the scheduled basis, recommended by current AGS guidelines.

### AGE-APPROPRIATE SCREENING FOR MEASURING OPIOID MEDICATION MISUSE IN COMMUNITY-DWELLING OLDER ADULTS WITH CHRONIC PAIN

J. Park, *School of Social Work, Florida Atlantic University, Boca Raton, Florida*

Assessing opioid medication misuse in geriatric populations is difficult due to absence of age-appropriate and validated instruments. The Pain Medication Questionnaire (PMQ) was developed based on risk factors associated with opioid medication misuse in chronic pain patients; it has been validated in a general pain population but not utilized specifically with the elderly. Factor analyses were conducted to identify age-appropriate subscales and scale items with the intent to develop a short version of the PMQ. Exploratory factor analysis and confirmatory factor analysis were performed on data collected from 163 older adults who had completed the PMQ. Two factors (maladaptive behaviors and efficacy of pain medication) and 7 items in these factors were identified. By accurately assessing opioid medication misuse with the revised PMQ, older adults may receive age-appropriate interventions and decrease health care utilization costs and hospital admissions by reducing adverse events due to drug misuse.

### LATE LIFE ADDICTIONS: EXAMINING TREATMENT APPROACHES AND OUTCOMES OF AN AGE-SPECIFIC CLINIC IN NYS

N.S. MacFarland, *University at Albany, Albany, New York*

Substance use disorders (SUDs) are of growing concern among the aging population in the US. As the baby boomers age, the number of seniors requiring services for alcohol/illicit drug abuse or dependence will likely grow in unprecedented numbers. Expanding available services for addicted seniors is of paramount importance. It is also critical that such services be tailored to the unique needs of this population and grounded in evidence-based practices. Provided will be a description of a NYS licensed chemical dependency outpatient clinic catering exclusively to the 50+ population, showing a 70% 3 month retention rate, 60% discontinued use rate, and a 53% increase in units of service. This program's treatment engagement and retention strategies, as well as a change project that contributed to even better outcomes in these areas, will be described. Implications for future practice and research in the area of late-life chemical dependency treatment will be summarized.

## SESSION 730 (SYMPOSIUM)

### EXPLORING GERIATRIC HEALTH CARE TRANSITIONS: NURSING ASSESSMENTS

Chair: *D.F. Mahoney, School of Nursing, MGH Institute of Health Professions, Boston, Massachusetts*

Discussant: *M. Henderson, School of Nursing, MGH Institute of Health Professions, Boston, Massachusetts*

Gerontologists have been charged to better illustrate and address the needs of older adults during significant transition points over their life course. This symposium presents four studies designed to increase understanding of issues involved at key transition points across the spectrum of U.S. health care settings and addresses providers, prescribers, and family caregivers. Both qualitative and quantitative research methods are represented. Mahoney will begin the symposium by presenting data from a content analysis of gerontological nurse practitioners' perceptions of issues that arise during prescription transition points across a variety of settings. Second, Rosenbloom-Brunton will focus on older adults' transitioning from home to the acute care hospital setting and report on her study of family caregivers' perceptions of facilitators and barriers to their involvement in their loved ones care during hospitalization. Third, Kelly will report on the practical findings from testing a minimum data set of communication items as a handoff tool to improve older adult's transitions from the skilled nursing facility to the acute care hospital. Fourth, Palan Lopez will address a final transition point moving into palliative care. Her study tests a theory of uncertainty based on Mishel's model of uncertainty with surrogate decision makers for nursing home residents with dementia to better understand how the model's tenets may guide care at this very difficult time. Finally, Henderson will lead the panel in a discussion of the implications these studies hold for policy, practice, and nursing care.

### PRESCRIBING TRANSITION POINTS: GERONTOLOGICAL NURSE PRACTITIONERS' PERSPECTIVES

D.F. Mahoney, E. Ladd, *School of Nursing, MGH Institute of Health Professions, Boston, Massachusetts*

As attention turns towards better understanding of issues that arise related to older adult's transitions across geriatric health care settings, the need to reconcile medications has surfaced as a key component. Despite practice and policy standards supporting reconciliation and coordination of drug therapy upon relocation from one setting to another, problems remain. The purpose of this study was to explore, through qualitative research, the perceptions of Gerontological Nurse Prescribers (GNPs) to assess their understanding of the issues that arise during prescription transition points. Two focus groups (n=15) were conducted by the authors at a national meeting of GNPs with a content analyses of their responses. Results revealed key issues related to the type of setting, variations in physicians' practice patterns, Medicaid/formularies, institutional "drug deals", family demands, packaging policies, and sample usage. GNPs provided a multi-faceted role that addressed transition barriers in a steadfast manner

### AIDING TRANSITIONS FROM HOME TO ACUTE CARE - NURSE/FAMILY CAREGIVER PARTNERSHIP

D. Rosenbloom-Brunton, *MGH Institute of Health Professions, Boston, Massachusetts*

Family members have critical knowledge about older adults admitted to acute care settings from home or long term care. Yet little is known about the barriers and facilitators of family participation in the older adult's inpatient care. To gain further understanding of their potential to inform caregiving, fifteen caregivers of older adults admitted to an urban teaching hospital were interviewed to identify concerns and potential for participating more in their family member's care. Content analysis revealed three themes that give clarity to barriers and facilitators for family participation: partnership, therapeutic relationships, and environment. These themes are exemplified by nurses working closely with the patient and family in a partnership, listening and being present to establish a therapeutic relationship, and providing a calm, unhurried environment, to support participation. Findings suggest the need for development and testing of interventions that promote cooperation between family caregivers and nurses through a family-centered care approach.

### TESTING A MODEL OF UNCERTAINTY IN DECISION MAKERS FOR NURSING HOME RESIDENTS WITH DEMENTIA

R. Lopez, A.J. Guarino, *MGH Institute of Health Professions, Charlestown, Massachusetts*

Uncertainty is a considerable barrier for surrogate decision makers (SDMs) to transition nursing home residents with dementia to palliative care. We assessed the direct and indirect effects of (a) Perceived Self-Efficacy, (b) Structure Providers, and (c) Stimuli Frame on Uncertainty from Mishel's Theory. Participants (N = 156) were SDMs for nursing home residents with dementia who completed a survey designed to measure the theory's constructs. Results of the path analysis indicated that both Perceived Self-Efficacy ($\beta$ = -.24, p < .01) and Structure Providers ($\beta$ = -.24, p < .01) explained 13% of the Uncertainty variance (p < .01). Higher levels of Structured Providers and Perceived Self-Efficacy had direct effects on lower levels of Uncertainty. There were no statistically significant indirect effects on Uncertainty. The re-specified model suggests that health care providers may attenuate SDMs Uncertainty by providing social support, credible information, and increasing SDMs' perceived-self efficacy for decision making.

### STANDARDIZED COMMUNICATION TOOL FOR HANDOFF COMMUNICATION FROM A SKILLED NURSING FACILITY TO AN ACUTE CARE HOSPITAL

N.A. Kelly[1], A. Bonner[2], T.A. O'Malley[3], *1. MGH IHP, Boston, Massachusetts, 2. Massachusetts Department of Public Health, Boston, Massachusetts, 3. Partners Continuing Care, Boston, Massachusetts*

Research into older adults' transitions of care between skilled nursing facilities (SNF) and acute care hospital settings is a key priority (Naylor and Keating, 2008). The Joint Commission has identified safe handoff communication as a national safety goal. However, there is no established standard of care involving such communication nor agreement upon the "minimum data set" needed for good communication. In response we developed, in concert with caregivers from both the SNF and acute care settings, a standardized communication tool containing mutually agreed upon key elements of communication. We present the findings from the development and initial pilot testing of this tool between one skilled nursing facility and one tertiary care hospital. Preliminary findings show improved communication of the key elements.

## SESSION 735 (PAPER)

## FINDING SUPPORT: FRIENDSHIP, FAMILY AND RELIGION

### AN ASSESSMENT TOOL FOR IDENTIFYING DEMENTIA CAREGIVER RESOURCES, VULNERABILITIES AND SERVICE NEEDS

E. Marziali, L. McCleary, *Baycrest, Toronto, Ontario, Canada*

Objectives: The aim of this study was to, 1) examine a battery of questionnaires for assessing the personal resources and vulnerabilities of family caregivers of persons with dementia (Alzheimer or other); and 2) determine allocation of services according to assessment of caregiver needs. Methods: A cross-sectional survey design was used to obtain dementia caregiver responses to questionnaires that focused on caregiver stress response, self-efficacy, physical/mental health status, personality and social support. Two hundred and thirty-two caregivers of family members with dementia were recruited. Data were collected by trained graduate and senior undergraduate allied health students. Results: Descriptively the sample was similar to that reported in most studies of dementia caregivers. Regression analysis showed that a personality factor (neuroticism) explained over 20% of the variance in caregiver mental health status and depression. With caregiver distress levels associated with different domains of care recipient disability as the dependent variables, personality and self-efficacy accounted for 15% to 17 % of the explained variance. Interpretation of individual score levels on each measure was linked to possible service needs. Conclusions: The results suggest that measures of personality factors, self-efficacy, mental health status, and distress response could be used for determining the combined service needs of caregivers and care recipients. Identifying levels of stress response according to separate domains of care recipient disability adds specificity to determining caregiver service needs. This individualized assessment approach could insure allocation of multi-component service programs that have been shown to be effective in sustaining caregiver role functions.

### COMPASSION FATIGUE IN INFORMAL CAREGIVERS

J. Day, *Nursing, Duke University, Durham, North Carolina*

**Background**: Compassion fatigue is a concept used with increasing frequency within the nursing and health care literature. Several scholars have defined compassion fatigue, but there is no commonly accepted definition. Compassion fatigue is often used synonymously with *caregiver burnout, secondary traumatic stress*, and *vicarious traumatization*. These concepts appear frequently in the fields of sociology and psychology however, there is little empirical research on compassion fatigue in the nursing literature. **Methods**: The Schwartz-Barcott and Kim hybrid model of concept development was used to analyze and redefine compassion fatigue based on existing empirical evidence. **Findings**: Compassion fatigue for informal caregivers is an experience of individuals in emotional relationships caring for individuals who are suffering. Compassion fatigue arises when the informal caregiver is unable to fulfill the desire to relieve the suffering of the care recipient. This disjunction causes the informal caregiver to feel helpless, apathetic, and withdrawn from the caregiving situation and may place the care recipient at risk for abuse, neglect, and premature admission to a nursing home. **Conclusions**: Research is needed to better understand the impact of compassion fatigue on informal caregivers, to identify informal caregivers at risk for compassion fatigue, and to provide an empirical basis for developing nursing interventions for caregivers experiencing compassion fatigue.

### MARRIAGE AND BIOLOGICAL RISK: EXAMINING THE QUANTITY AND QUALITY OF MARITAL RELATIONSHIPS

C.J. Donoho[1], E. Crimmins[1], T. Seeman[2], *1. University of Southern California, Los Angeles, California, 2. University of California, Los Angeles, Los Angeles, California*

Substantial evidence indicates that social relationships play a significant role in health outcomes ranging from catching the common cold to mortality. The health benefits experienced by married adults are well documented and are thought to reflect stable access to social, emotional, and tangible support. However, marital status does not account for the quality of marital relationships or the duration of time spent in and out of marital relationships. Duration and quality may interact such that long high-quality relationships may be salutary and long low-quality relationships may be detrimental. Using data from two waves of the Survey of Midlife in the US (N = 1024; age range: 35-86) we model the relationship between marital quality (global satisfaction, support, strain) and duration with a 17-marker index of cumulative biological risk with four sub-indices (inflammatory, cardiovascular, metabolic, and neuroendocrine). Controlling for age, regression analyses indicated that compared to continuously married men, never married and remarried men had more cumulative risk factors, respectively. Never married women had more inflammatory risk factors than continuously married women. For women with a history of disruption, longer disruptions were related to higher levels of inflammatory risk, but this was attenuated with the addition of marital quality 10 years earlier. Among the continuously married, higher marital quality was associated with lower biological risk for women, but not men. The present study elucidates the psychosocial and physiological mechanisms through which marriage affects health outcomes and disease processes.

### DISCUSSION OF INPATIENTS' RELIGIOUS AND SPIRITUAL CONCERNS DURING HOSPITALIZATION

J.A. Williams[1], D. Meltzer[2], V. Arora[2], G. Chung[3], F.A. Curlin[3], *1. Pritzker School of Medicine, University of Chicago, Chicago, Illinois, 2. Section of Hospital Medicine, Department of Medicine, The University of Chicago, Chicago, Illinois, 3. Section of General Internal Medicine, Department of Medicine, The University of Chicago, Chicago, Illinois*

Background: Religious physicians are much more likely to discuss religion and spirituality (R/S) issues with patients, but little is known about which patients desire and engage in discussions about religious and spiritual issues. Methods: We examined data from the University of Chicago Hospitalist Study, which gathers sociodemographic and clinical information from all consenting general internal medicine patients at the University of Chicago Medical Center. Primary outcomes were whether or not patients desired to have their religious or spiritual concerns addressed while hospitalized, whether or not anyone talked to them about religious and spiritual issues, and which member of the health care team spoke with them about these issues. Primary predictors were religious attendance, trying hard to carry one's religious beliefs over into other dealings in life, and self-rated spirituality. Results: Forty-one percent of inpatients desired, and 32% reported having, a discussion of R/S concerns while hospitalized. Some (20%) desired a conversation but did not have it, and 11% did not desire a conversation yet had it anyway. Religious patients and those experiencing more severe pain were more likely both to desire and to have discussions of spiritual concerns. Patients who discussed R/S concerns were more likely to be extremely satisfied with their medical care (74% vs. 63%, OR 1.7, 95%CI 1.4-2.0), regardless of whether or not they had wanted such discussion to occur. Conclusions: Many patients welcome conversations about R/S. Discussing R/S concerns with patients may improve their assessment of their hospital stay.

## SESSION 740 (SYMPOSIUM)

### IMPROVING HEALTH BY TRANSITIONING CARE OF OLDER ADULTS IN RURAL ARKANSAS THROUGH TELEHEALTH

Chair: *A. Overton-McCoy, UAMS-Texarkana Regional Center on Aging, Texarkana, Arkansas*
Discussant: *K. Shea, Arizona State University, Phoenix, Arizona*

This session will demonstrate how the transition of care within the geriatric population in rural Arkansas has impacted healthcare outcomes. Arkansas is a rural state, in which a large percentage of older adults reside with chronic illnesses. Arkansas is categorized as having an above average population of those 65 years of age and older. Arkansas also ranks in the top five states for older residents with chronic illnesses. Arkansas has implemented programs for the rural senior population that utilize advanced healthcare technology to increase healthcare access and improve health outcomes. The objective of this symposium is to bring together the collection of programs that have utilized technology for health benefits in acute care settings, primary care settings, and the private homes' of older adults. Healthcare in rural settings is limited, often to the extent specialty care is non-existent in many of the most outlying rural areas. Rural emergency rooms often lack the neurologists needed to diagnose strokes and facilitate the appropriate treatment. Older adults in rural areas may not have transportation to travel the required distance to see a geriatrician in a metropolitan area. Rural older adults have gained the ability to self-manage chronic diseases from home with the assistance of advancing technology. The programs identified herein demonstrate that an older adults can receive access to quality specialized healthcare regardless of their residency in a rural areas. Telehealth technology demonstrates the ability to increase healthcare accessibility. Telehealth technology provides positive health outcomes.

### THE ARKANSAS AGING INITIATIVE PROMOTING A HEALTHIER LIFE FOR ARKANSAS SENIORS: USING TECHNOLOGY TO INCREASE ACCESS AND AUGMENT AND EXPAND GERIATRIC WORKFORCE

C.J. Beverly, R.E. McAtee, *College of Nursing, University of Arkansas for Medical Sciences, Little Rock, Arkansas*

Arkansas is one of five states with the highest rates of chronic illnesses in the nation and the highest stroke death rate. The state's top two causes of mortality are heart disease and cancer. Further, Arkansas is a predominantly rural state, with 84% of its 75 counties classified as rural or nonmetropolitan, and 55 (73%) classified as medically underserved. And with respect to workforce, Arkansas is experiencing one of the worst physician and nurse shortages in the country. We will discuss strategies the Arkansas Aging Initiative has employed to have a better prepared geriatric workforce and to expand and augment the current workforce throughout the state. Increased access to interdisciplinary geriatric care for patients living in rural parts of the state will also be presented.

### ONE LINK, MANY LIVES: OUTCOMES OF A RURAL TELESTROKE PROGRAM

J. Hall-Barrow, T. Benton, T. Imus, S.G. Keyrouz, *Center for Distance Health, University of Arkansas for Medical Sciences, Little Rock, Arkansas*

Arkansas SAVES (Stroke Assistance through Virtual Emergency Support) improves emergency care for stroke patients in the rural state of Arkansas through telemedicine. This program helps rural emergency rooms diagnose stroke patients and improve their outcomes through real-time, interactive video. Telemedicine unites remote neurologists in real-time with rural stroke patients on an around-the-clock basis, creating a virtual environment where rural patients can seek the level of care afforded to patients at urban medical centers. This program has increased the administration of tPA among rural populations that lacked access to emergency neurological care prior to telemedicine collaboration. Through training, public awareness, and quality control, Arkansas SAVES continues to grow and improve with reducing response times by 50% since the project's pilot phase.

### GERIATRIC TELEMEDICINE: TRANSITIONING CARE TO OLDER ADULT'S RURAL COMMUNITIES

A. Overton-McCoy, M.S. Bishop, *UAMS-Texarkana Regional Center on Aging, Texarkana, Arkansas*

Southwest Arkansas has one of the highest percentages of populations of individuals that are 65 years of age and older within both the state of Arkansas and within the nation. Health services and geriatric expertise are limited within this area of the state. It is vital to explore proficient methods to increase geriatric clinical services to rural Southwest Arkansas while allowing this population to stay within their own communities. Through telemedicine services a plan was formulated to increase access to geriatric specialty care in a cost effective manner to older adults who live in the rural communities in south Arkansas. The telemedicine services will allow an extension of geriatric interdisciplinary care and educational services to these rural areas in a holistic manner. Telemedicine can provide services to long-term facilities with access to geriatric specialties without the patient being discharged from the facility.

### HOME MONITORING THROUGH TELEMEDICINE TO IMPROVE CHRONIC DISEASE MANAGEMENT OF MEDICARE BENEFICIARIES

K.A. Allen[1,2], L. Nelson[1,2], L. Russell[2], *1. Care Improvement Plus, Fort Worth, Texas, 2. XLHealth, Baltimore, Maryland*

Care Improvement Plus is a Medicare Advantage organization committed to delivering quality healthcare to Medicare beneficiaries. Care

Improvement Plus uses telemedicine in its implementation of preventive care, care coordination and disease management. Two specific programs are the PharmAssist Call Center and the 24-Hour Nurse Hotline. The PharmAssist Program is monitored by specialized pharmacists available 24/7 to answer beneficiaries' medication questions. The 24-Hour Nurse Hotline is available 7 days a week to assist members in understanding health concerns, locating health providers, and seeking appropriate after hour care. A third use of telemedicine is the placement of real-time monitored cardio scales in homes of high risk cardiac patients. This session will present the cumulative implementation of these telemedicine programs regarding patient outcomes and access to care. Additional information will be presented in how these programs are successful in assisting in beneficiary disease self-management and improving medication compliance.

## SESSION 745 (PAPER)

## PHYSICAL FUNCTION AND REHABILITATION

### EFFECTS OF WEIGHT LOSS, EXERCISE, OR COMBINED ON PHYSICAL FUNCTION IN FRAIL, OBESE OLDER ADULTS

D.T. Villareal[1,2], S. Chode[2], N. Parimi[2], D. Sinacore[2], T. Hilton[3,2], C. Qualls[1], K. Shah[3,2], *1. University of New Mexico School of Medicine - New Mexico VA Health Care System, Albuquerque, New Mexico, 2. Washington University School of Medicine, St Louis, Missouri, 3. University of Rochester School of Medicine, Rochester, New York*

BACKGROUND. Although obesity causes frailty in obese older adults by exacerbating the age-related decline in physical function, appropriate treatment is controversial. METHODS. We conducted a 1-year randomized-controlled trial to evaluate the independent and combined effects of weight loss and exercise on physical function, body composition, and QOL in 107 obese (BMI≥30 kg/m2) older (≥65 yrs) adults. They were randomized to Diet-only, Exercise-only, Diet+Exercise, and Healthy-Lifestyle (HL) groups. RESULTS. Ninety-four (87%) participants completed the study; adherence was 82% for diet and 81% for exercise interventions. Diet-only and Diet+Exercise induced weight loss (-10%), whereas Exercise-only and HL maintained weight (-0.5%) (between-group P<.05). Exercise-only and Diet+Exercise improved (27-34%) muscle strength, whereas Diet-only and HL maintained strength (1%) (P<.05). Although Diet-only and Exercise-only improved (11-15%) physical performance test (PPT) scores, Diet+Exercise improved (21%) PPT more than either intervention only (P<.05). Moreover, although Diet-only and Exercise-only improved (8-10%) VO2peak, Diet+Exercise improved (17%) VO2peak more than either intervention only (P<.05). Furthermore, Diet-only and Exercise-only improved (4-6%) functional status questionnaire (FSQ) scores, but Diet+Exercise improved (10%) FSQ more than Diet-only (P<.05). Diet-only decreased (-6%) muscle mass while Diet+Exercise attenuated this decrease (-2%) (P<.05). Diet-only and Exercise-only improved obstacle course and limb stance scores (27-55%), while Diet+Exercise improved limb stance (160%) more than Exercise-only (P<.05). Exercise-only (14%) but not Diet-only improved gait speed. All interventions improved (10%) SF-36 physical subscale scores (P<.05). CONCLUSIONS. Combined weight loss and regular exercise provides greater improvement in physical function than either intervention only and is therefore recommended to treat obese older adults.

### DOES HISTORY OF FALLING PREDICT LENGTH OF STAY IN POST-ACUTE GERIATRIC REHABILITATION?

E. Martin[1], R. Dreher[2], S. Rochat[1], C.J. Bula[1], *1. University Medical Center, Lausanne, Switzerland, 2. Ensemble hospitalier de la Côte, Morges, Switzerland*

**Objectives:** To investigate the associations between falls before hospital admission, falls during hospitalization, and length of stay in elderly people admitted to post-acute geriatric rehabilitation. **Method:** History of falling in the previous 12 months before admission was recorded among 249 older persons (mean age 82.3±7.4 years, 69.1% women) consecutively admitted to post-acute rehabilitation. Data on medical, functional and cognitive status were collected upon admission. Falls during hospitalization and length of stay were recorded at discharge. **Results:** Overall, 92 (40.4%) patients reported no fall in the 12 months before admission; 63(27.6%) reported 1 fall, and 73(32.0%) reported multiple falls. Previous falls occurrence (one or more falls) was significantly associated with in-stay falls (19.9% of previous fallers fell during the stay vs 7.6% in patients without history of falling, P=.01), and with a longer length of stay (22.4 ± 10.1 days vs 27.1 ± 14.3 days, P=.01). In multivariate robust regression controlling for gender, age, functional and cognitive status, history of falling remained significantly associated with longer rehabilitation stay (2.8 days more in single fallers, p=.05, and 3.3 days more in multiple fallers, p=.0.1, compared to non-fallers). **Conclusion:** History of falling in the 12 months prior to post acute geriatric rehabilitation is independently associated with a longer rehabilitation length of stay. Previous fallers have also an increased risk of falling during rehabilitation stay. This suggests that hospital fall prevention measures should particularly target these high riskpatients.

### MUSCLE FUNCTION AND FUNCTIONAL PERFORMANCE IN ASSISTED LIVING RESIDENTS AFTER PARTICIPATION IN A QUANTITATIVE PROGRESSIVE EXERCISE REHABILITATION PROGRAM

C. Montgomery[1], N. Fisher[2], C.V. Granger[3], M.R. Tomita[2], *1. SUNYAB School of Nursing, Buffalo, New York, 2. SUNYAB Department of Rehabilitation Science, Buffalo, New York, 3. SUNYAB Department of Rehabilitation Medicine, Buffalo, New York*

An 8-week quantitative progressive resistance exercise rehabilitation (QPER) program was investigated to determine muscle function (strength, endurance) and functional performance (6-minute walk distance, stair climb time) changes in assisted living (AL) residents. Forty-five AL residents, mean age = 85.6±6.1 years, were randomized to either QPER (EX, n=30) or C (n=15). All participants were tested at pre and post-intervention, and then 6 months after cessation of exercise. Tests included maximal isometric strength and endurance of the quadriceps and hamstrings, 6-minute walk distance and stair climb time. After 8-weeks, three participants had dropped from EX and none from C. The post-test results showed that EX had significant increases in quadriceps (50%) and hamstring (77%) strength, quadriceps (103%) and hamstring (1382%) endurance, 6-minute walk distance (7%) and stair climb time (3%), while C had significant decreases in strength (11% and 14% for quadriceps and hamstrings, respectively), endurance (27% and 54%, respectively), 6-minute walk distance (7%) and stair climb time (13%). At 6 months follow-up, the group sizes were 20 in EX and 10 in C. However, EX was still significantly above baseline for quadriceps (76%) and hamstring (95%) strength and endurance (76% and 136% for quadriceps and hamstrings, respectively) and maintained their stair climb time. C had continual decreases in strength and endurance. Their stair climb time was significantly worse (24%, p<.01). In conclusion, QPER is an effective resistance training program for assisted living residents that may be used to help this population age in place instead of transferring to a nursing home.

### GETTING HOME: A NATIONAL STUDY OF VARIATION OF OUTCOMES OF COMMUNITY BASED HIP FRACTURES

N. Leland[1], J. Bynum[2], P.L. Gozalo[1], V. Mor[1], T. Wetle[1], J.M. Teno[1], *1. Center for Gerontology and Health Care Research, Brown University, Providence, Rhode Island, 2. Dartmouth College, Hanover, New Hampshire*

Returning to independent living is an important goal of hip fracture rehabilitation. This study examined state variation in discharge location and time to return home between those discharged to an inpatient rehabilitation facility (IRF) or skilled nursing facility (SNF). Discharge location and time from hospital discharge to spending 30 days at home was examined among Medicare Beneficiaries 75 and older at the time of first hip fracture without a nursing home (NH) stay in 180 days prior to the fracture between 1999 and June 1 2007. State variation in discharge location and median time to getting home are reported. A Cox Proportional Hazard model was used to examine the timing of transition to home among person discharge to SNF and IRF after adjustment for age, gender, race, and measures of comorbidity. Of 1,210,366 patients, 64.5% did not have a NH stay prior to hip fracture. Of these, 77.4% were discharged home with a stay of at least 30 days. There was state variation in use of IRF ranging from 4.86% (Oregon) to 56.36% (Arkansas). Among those discharged to SNF or IRF (n=626,005), 81% were discharged home varying between 75.82% (Louisiana) and 86.40% (Connecticut). Using a Cox Proportional Hazard model, state use of IRF (states in the lowest quintile: Hazard Ratio 1.17, 95% CI 1.11-1.13) and race are significant in predicting getting home (Blacks: Hazard Ratio 0.78, 95% CI 0.77-0.80). There is a significant geographic and racial variation in discharge location and the time to get home after a hip fracture.

## SESSION 750 (SYMPOSIUM)

### SERIOUS GAMES FOR HEALTHY AGING: BEYOND THE BRAIN GAME REVOLUTION

Chair: *E. Crimmins, University of Southern California, Los Angeles, California*
Co-Chair: *C. Winstein, University of Southern California, Los Angeles, California*
Discussant: *E. Zelinski, University of Southern California, Los Angeles, California*

Confronting declines in cognitive and physical function that accompany aging has provided motivation for the development of serious games. Games are enjoyable, motivating, and engaging which can encourage regular and consistent use and in turn foster benefits. Recent developments in simulations and video games for cognitive functions, physical exercises and rehabilitation of those aging with and into disability has attracted the attention of scholars and consumers. The objective of this session is to synthesize information that has motivated these developments and some of the promising cognitive, physical, and rehabilitative outcomes associated with the use of interactive games for healthy aging. Each talk highlights a unique aspect of technology or outcomes targeting specific applications. First, with an increase in the number of older adults living with long-standing neurological disorders, including multiple sclerosis, there is significant impetus for the development of computer aided and telehealth interventions targeting cognitive rehabilitation. Second, in response to recent federal physical activity guidelines promoting the importance of balance, strength and aerobic training to prevent falls, commercially available video game exercises are now being used to improve balance and reduce falls in community dwelling older adults. Finally, while innovations in movement-controlled video games offer the rehabilitation community a novel and motivating alternative to traditional rehabilitation exercises, technological modifications to commercial games are needed to better address balance and falls for individuals aging with and into disabilities. Technological advances include modified game devices that now integrate a clinician interface, impairment assessment, intervention and outcomes.

### COGNITIVE DIFFICULTIES AND THE ROLE OF COGNITIVE REHABILITATION IN ADULTS AGING WITH NEUROLOGICAL DISEASE

I.R. Molton, M.P. Jensen, *University of Washington School of Medicine, Seattle, Washington*

It is well known that the prevalence of disabling neurological conditions, such as vascular dementia, increases with age. What is less well known is that, due to recent medical advances, the population of older adults living with long-standing neurological disorders such as Multiple Sclerosis and neuromuscular disease has also increased dramatically. These individuals represent a rich intervention target for cognitive rehabilitation, and particularly for computer aided and "telehealth" interventions that can be adapted to accommodate for physical limitations and other barriers to accessibility. This talk will review common cognitive difficulties associated with several "early onset" neurological disabilities. We will also discuss the intersection of these cognitive limitations with normative brain changes in aging, and will discuss potential areas for computer and game aided cognitive rehabilitation in this population.

### ACTIVE VIDEO GAME EXERCISE TO IMPROVE BALANCE AND REDUCE FALLS IN COMMUNITY-DWELLING OLDER ADULTS

J. Rowland, *University of Illinois at Chicago, Chicago, Illinois*

Falls and fall-related injuries pose serious threats to the health and wellbeing of older adults. Recently-published federal physical activity guidelines highlight the importance of balance, strength, and aerobic training to prevent falls. Despite the overwhelming evidence that exercise-based programs can prevent falls in older adults, this cohort remains one of the most sedentary of any age group. One novel approach to increasing physical activity in the general population in recent years has been active video games such as the Wii Fit Plus. Results will be presented in the following context: Hypothesis 1: Older adults participating in the Wii Fit Plus exercise program will demonstrate: a) Increased dynamic and static standing balance; b) Increased lower extremity strength and flexibility; c) Improvements in cardiorespiratory fitness; Hypothesis 2: Older adults participating in the Wii Fit Plus exercise program will decrease their fear of falling as evidenced by scores on the Falls Efficacy Scale.

### INTERACTIVE GAME-BASED REHABILITATION TOOLS: NEVER TOO OLD TO PLAY

S. Flynn, B. Lange, C. Chang, B.L. Kennedy, A.". Rizzo, *University of Southern California, Los Angeles, California*

Innovations in movement-controlled interface devices and video games offer a novel and motivating alternative for promoting activity and rehabilitation across the lifespan. Already, game industry giants are developing products (Nintendo Wii, Sony EyeToy, Microsoft Xbox Project Natal) that aim to capitalize on the billion-dollar exergaming (and potential rehabilitation) market. The focus of this presentation is on our lab's efforts in two areas: 1) the modification and use of these existing commercial systems, such that meaningful rehabilitation activity can be implemented, and 2) the creation of new games and interface devices that are specifically designed to enhance rehabilitation activities based on good science. We will present our work on the design/evaluation of VR systems that aim to enhance balance and reduce falls in those aging with disabilities and demonstrate prototypes that allow a clinician to modulate game parameters for optimizing assessment and intervention based on an individual's level of impairment.

# SESSION 755 (POSTER)

## TECHNOLOGY, EDUCATION AND ATTITUDES

### “ADAPTING TO HEALTH CHANGE” PROGRAM ENCOURAGES MEDICAL STUDENT EMPATHY FOR SENIORS

T. Teasdale[1,2], S.A. Mapes[1], K. Sharp[1], J. Belzer[1], *1. Dept of Geriatric Medicine, University of Oklahoma, Oklahoma City, Oklahoma, 2. Veterans Affairs, Oklahoma City, Oklahoma*

Healthcare students often have (or absorb) societal conceptions and misconceptions about the aged. A required “Adapting to Health Change” program was started for medical students in 1997 to teach empathy for changes older adults often encounter during the aging process, and to develop common sense methods for helping patients cope with diminishing abilities. To date, 1,987 MS2s have participated in the two-hour simulation training. The unique element of this very interactive experience becomes evident when students assume “roles” in the form of diagnoses and are outfitted with appropriate gear to experience the associated impairments. Simulation equipment includes ear plugs, vision impairment glasses, gait and digit restrictors, wheelchairs, canes, walkers and (yes) adult diapers. A short introduction to physical impediments to normal aging is presented. Older volunteers and staff then guide the students through five stations designed to mimic ADL/IADL tasks. A final thirty minute debriefing period with a geriatrician reinforces learning points and encourages discussion. With their “limitations,” students found that managing pills, dressing, eating, etc rate high in difficulty and many question how elderly patients with physical deficiencies are able to handle the tasks (qualitative data). Quantitative data reveal that 64% “strongly agree” with four positively worded, Likert-like evaluative questions regarding the exercise; another 26% endorsed “agree”, resulting in a 90% approval rating. Medical school faculty and students are pleased with this required experience. A newly developed, exportable version (ASiST) appropriate for multiple disciplines will be available for exploration at the poster.

### LEARNING BY LIVING © RESEARCH PROJECT: A CULTURE OF AGING LIVED BY MEDICAL STUDENTS

M. Gugliucci, *University of New England, Biddeford, Maine*

Medical schools do not prepare future physicians in how to work effectively with elders living in nursing homes. With the inherent shortage of trained physicians in caring for older adults, the Learning by Living © project has proven to be a unique and effective approach for medical student learning. Learning by Living © applies a Qualitative Ethnographic and Biographic research design that involves “admitting” medical students into nursing homes to live the life of an elder nursing home (NH) resident for 2 weeks – 24 hours per day – complete with a medical diagnosis and “standard” procedures of care (toileting, transferred, bathed, fed (pureed foods, etc). The researcher (medical student) observes a “culture” while living within an environment (nursing home). Data collection by students (18 have been admitted thus far) occurred through journal writing during pre-fieldwork (preparing to enter the nursing home); fieldwork (while living in the nursing home); and post-fieldwork (upon leaving the nursing home). Data analysis is conducted using manual qualitative research analysis and N-VIVO software. Sample themes include communication, dependence, routine, and care. Findings are enduring: increased understanding of touch and eye contact; increased ability to communicate using voice tone, body language, word usage and cadence; consciousness regarding the role of routine in a person’s life and connecting heart to heart with older adults regardless of disease or degree of frailty. Learning by Living © has provided a precedent to help our society change our negative views of nursing homes and instill new models of care.

### INTERPROFESSIONAL QUALITY IMPROVEMENT (QI) LEARNING ACTIVITY FOR SENIOR NURSING STUDENTS AND GERIATRIC MEDICINE FELLOWS

G.T. Buhr[1], M. Yanamadala[1,4], J. Gontarz[2], B.J. Dotson[2], S.M. Williams[2], E.S. McConnell[3,4], *1. Medicine/Geriatrics, Duke University Medical Center, Durham, North Carolina, 2. Watts School of Nursing, Durham, North Carolina, 3. Duke University School of Nursing, Durham, North Carolina, 4. Durham VA, GRECC, Durham, North Carolina*

Both medicine and nursing endorse practice-based improvement and interprofessional teamwork and collaboration as core competencies – skills best learned through hands-on experiences. Geriatric medicine fellows and senior pre-licensure nursing students were introduced separately to the FOCUS- Plan-Do-Study-Act QI model. As part of a year-long longitudinal long-term care experience, the fellows developed QI proposals with mentoring from faculty. Two teams of 2 fellows and 19 nursing students were formed. The nursing students used literature to modify the proposals. The fellows collaborated with subgroups of the nursing students in two 6-week blocks to collect baseline data, carry out a small test of change, and collect post-intervention data. The experience was evaluated with pre and post self-efficacy surveys of QI and interprofessional collaboration skills (6 point scale); the QI proposals were assessed using the QI Proposal Assessment Tool (QIPAT-7); and the fellows’ knowledge was assessed with the QI Knowledge Application Tool (QIKAT). Baseline data showed the nurses were more confident in their ability to collaborate with other professionals (5.46) and locate strong evidence (4.56), yet less confident in constructing a run chart (3.57) and data analysis plan (4.11). The fellows felt confident in formulating a data collection plan (5.5), yet less confident in carrying out the data analysis plan (4.25). At baseline, the fellows needed practice-based improvement training as assessed by the QIKAT (1.7 out of 5). This innovative learning activity targeted fellows and nursing students, offering opportunities to improve teamwork and collaborative skills. This approach should be applicable to other groups of learners.

### GERIATRIC GEMS AND PALLIATIVE PEARLS: SPACED EDUCATION AND CASE STUDY RESULTS

J. Larson, N. Ahmed, M. Hossain, *Dept. of Medicine, The University of Texas- Health Science Center- Houston, Houston, Texas*

Purpose: Spaced education has proven to be an efficient delivery system (Kerfoot, Kearney et al. 2009; Kerfoot 2010) for improving resident knowledge (Spitzer 1939; Roediger and Karpicke 2006). The purpose of this study was to determine if spaced education improved patient management measured by Design-A-Case. Design-A-Case is a web-based application that focuses on patient management through an interactive case. Methods & Materials: Six PGY02 residents from internal medicine were assigned to cohort A, the intervention group, and three PGY02 family medicine residents were assigned to cohort B, the control group. Cohort A received spaced education in the form of weekly “sound byte,” emails that contained a catchy teaching point and a link to a website containing more information on the topic. At the end of the month, both cohorts were asked to complete a topic related Design-A-Case. The grader was blinded to the participant’s cohort and scored the case based on the answers originally developed with the case. Results: A simple linear regression model was used to analyze the data. The model was fit to the response variable with the intervention as a covariate on both the adjusted and unadjusted scores. The adjusted score demonstrated a significant intervention effect p=0.0316. Conclusions: Spaced education contributes to resident’s ability to correctly answer a geriatric case and may assist residents in managing geriatric patients as evidence by improved scores when completing a Design-A-Case. Limitations: Due to the small sample size, findings cannot be generalized beyond this group.

### IMPROVING RESIDENT SAFETY IN NURSING HOMES: PRIORITIES FOR FRONT LINE STAFF EDUCATION

V. Shier[4], S. Taylor[1], D. Saliba[2,3,1], *1. RAND Corporation, Santa Monica, California, 2. VA Greater Los Angeles GRECC, Los Angeles, California, 3. UCLA/JH Borun Center for Gerontological Research, Los Angeles, California, 4. Pardee RAND Graduate School, Santa Monica, California*

Purpose: In the past two decades, hospitals have made substantial efforts to implement patient safety practices and reduce medical errors, while efforts to adopt these safety principles in the nursing home (NH) setting have lagged behind. Educational curriculum for front line NH staff will support the translation of safety research into actual improvements in NH care. We sought stakeholder input on prioritization of resident safety improvement issues which will be addressed through the development of educational materials. Methods: We assembled a national NH patient safety expert panel that included representatives from multiple stakeholder groups. Panelists were provided with a listing of existing guidelines and safety targets set by national groups. They individually ranked their top five resident safety issues based on the criteria: a) the process to outcome link is defined enough to develop educational material, b) front line staff play a significant role in the resident safety issue, c) prevalence, and d) impact on patient outcomes and quality of life. During the meeting, panelists discussed importance of each of the issues and then again ranked their top five issues post-meeting. Results: Panelists identified falls prevention and recognition and response to changes in resident's condition as the top two resident safety needs in NHs in both pre-meeting rankings and post-meeting rankings. Some panelists ranked pressure ulcer prevention, while others felt the topic had already received significant national attention. Pain detection and management and drug safety were also ranked as top resident safety needs.

### SIMULATION: A MILLENNIAL INNOVATION FOR ENHANCING GERONTOLOGICAL CONTENT IN A NURSING CURRICULUM

L.M. Underwood, *University of Utah - Hartford Center, Salt Lake City, Utah*

An eleven fold increase this century in those over 65 exceeds the growth rate of the entire population. With changing demographics of the American population, nurses will likely spend a majority of their practice time caring for older adults with diverse and complex health needs. Nursing educators are often challenged to provide quality student learning experiences to support student interest and competence in caring for older adults without the addition of a separate geriatric course. This poster presents a millennial approach to integrating gerontology nursing education standards within a set curriculum. High-fidelity simulation provides a flexible, interactive, clinical learning approach to addressing the care needs of older adults. Educators are only limited by their imagination as simulation, unlike the clinical setting, can duplicate real-life clinical experiences for all students. Simulation provides opportunities for incorporating communication, psychomotor skills, clinical judgment, teamwork, and delegation while addressing the individualized physical, safety, and psychosocial needs of the patient and family. Through pre-briefing and debriefing sessions, nursing educators can take advantage of teachable moments to clarify content and to discuss legal, ethical, and social issues unique to the care of older adults and their families. Time and resource investments in high-fidelity simulation enhance gerontological nursing education by providing real-life simulated clinical learning experiences in a safe, risk-free environment. Simulation conveys respect for the well being of older patients and their families as recipients of compassionate and competent care rather than as task focused opportunities for student skill practice in the clinical setting.

### EFFECTS OF HEALTH INFORMATION TECHNOLOGY ADOPTION ON QUALITY OF CARE AND PATIENT SAFETY IN US ACUTE CARE HOSPITALS

B. Seblega[1], N.J. Zhang[1], T. Wan[1], L. Unruh[1], R. Hillestad[2], *1. PhD in Public Affairs, University of Central Florida, Orlando, Florida, 2. Pardee RAND Graduate School, Santa Monica, California*

Healthcare information technology (HIT) is advocated by policy makers, healthcare providers, consumer groups, as well as concerned organizations such as Institute of Medicine (IOM), Agency for Healthcare Research and Quality (AHRQ), and The Leapfrog Group as critical in addressing the growing crisis in the healthcare industry. The primary objective of this research is, therefore, to understand the relationship between the adoption of HIT in US acute care hospitals and two important healthcare outcomes: patient safety and quality of care. This is accomplished by building a regression model with HIT adoption as an independent variable and patient safety and quality of care as dependent variables after controlling for organizational and environmental factors. We used data from 2006 obtained from three different sources: AHA Annual Survey, HIMSS Analytics Annual Survey and HCUP data set. The findings indicate that in 2006 the adoption of HIT was positively associated with for-profit ownership, HMO penetration, urban location, small size, and membership of an Integrated Delivery System (IDS). In addition, the relationship between the adoption of HIT and the two healthcare outcomes, i.e. patient safety and quality of care, was found not to be statistically significant. On the other hand, patient safety is positively associated with for profit ownership, urban location, and higher proportion of Medicare and Medicaid patients, while quality of care is positively associated with higher proportion of Medicare and Medicaid patients and negatively associated with higher full-time equivalent of personnel and IDS membership.

## SESSION 760 (SYMPOSIUM)

### ADDRESSING THE CHALLENGES OF RURAL AGING: INNOVATIONS AND SOLUTIONS FROM RURAL AMERICA

Chair: *J. Crittenden, Center on Aging, University of Maine, Bangor, Maine*

Discussant: *D. Wagner, Towson University, Towson, Maryland*

Rural elders face numerous challenges to healthy aging including a traditional lack of access to critical transportation, healthcare, and support services. Rural older adults have poorer health outcomes and are more economically disadvantaged when compared to their urban counterparts. However, despite these challenges there exists a growing body of evidence that rural elders and community members are developing innovative and creative ways to manage what may appear to be unmanageable situations. As our rural communities continue to confront the many challenges of scarce resources, increasing level of need among residents, and an increase in older residents, it is imperative that rural researchers, advocates and educators share the homegrown success stories of innovation and solutions. This symposium will examine how rural elders are able to overcome and compensate for the lack of resources and the barriers that challenge independent living in nonmetropolitan areas, to support their own healthy aging. Symposium presentations will explore specialized topics and research on developing informal support networks, empowering rural older adults to manage their own health, innovative strategies for engaging older adults in identifying the needs of their communities, and best practices for providing support and outreach to rural grandfamilies. Presentations will highlight the use of innovation and the potential for rural areas to serve as an incubator, in particular, for community-based and person-centered solutions that support healthy and active aging.

### LESSONS IN TRANSITION EXPERIENCED BY CUSTODIAL GRANDPARENTS IN A RURAL SUPPORT GROUP

T.L. Peterson[1,2], M.R. Crowther[1,2], *1. University of Alabama, Tuscaloosa, Alabama, 2. Center for Mental Health and Aging, Tuscaloosa, Alabama*

An estimated 2.4 million Americans are custodial grandparents. Though raising a grandchild can have benefits, custodial grandparenting can pose substantial stress. For rural residents, the strain and rewards of custodial grandparenting is compounded by limited resources, increased risk of poverty, and geographic isolation. This paper will describe transitions experienced by custodial grandparents attending a rural support group. Data collection involved co-facilitators observing a monthly support group. The findings revealed five areas of transitions: managing household finances, navigating community-based organizations, adjusting to rural school systems, discussing adolescent issues, and integrating technology in the home. Support groups can benefit rural custodial grandparents. Learning Objectives After attending this session, participants will be able to: 1. Identify characteristics of rural custodial grandparents 2. Discuss key transitions faced by rural custodial grandparents 3. Identify strategies to improve support to rural custodial grandparents

### COACHING AGING RURAL COMMUNITIES TOWARD HEALTH

R. Oscarson, S. Stluka, *South Dakota State University, Brookings SD, South Dakota*

The overall goal of this USDA (NIFA)-funded project was that rural South Dakota communities become contexts which support healthy behaviors and provide adequate access to services. Using a professional coaching model, this project enabled middle-aged and older adults in nine rural communities to prioritize local health concerns, identify desired health outcomes, and mobilize resources to reach designated outcomes. Coaching was delivered to rural communities by SD Extension Educators who first received coach training. We will provide an overview of the project's objectives, the coaching process, community goals and efforts, lessons we learned, and future directions.

### STRATEGIES FOR REMAINING INDEPENDENT WHILE GROWING OLDER IN RURAL COMMUNITIES

A.L. Cohen, *Sociology and Gerontology, Miami University, Oxford, Ohio*

Older adults aging in rural areas face challenges accessing both informal assistance from family, friends, and others and paid formal assistance from a variety of professional agencies. Despite these challenges, many rural elders have been able to construct and maintain support networks that assist them with the daily struggles of growing older in rural communities. This paper presents results from a exploratory and descriptive qualitative study which took place in rural the Appalachian Region of North Carolina. One-on-one Interviews were conducted with 16 rural elders, eight support network members and staff from six HCBS provider agencies. Results reveal strategies that rural elders use to create and sustain support networks as they develop physical challenges that limit their ability to care for themselves.

### USING PICTURES TO INDEX HEALTH CONCERNS AMONG RURAL ECONOMICALLY DISADVANTAGED ELDERS IN LOUISIANA

K. Kopera-Frye[1], M.A. Alibeli[1], K.Y. Griffin[1], M. Hall[2], F. Fathi[3], *1. Dept. of Gerontology, Sociology, & Political Science, University of Louisiana at Monroe, Monroe, Louisiana, 2. University of Louisiana at Monroe, Psychology Dept., Monroe, Louisiana, 3. University of Louisiana at Monroe, Biology Dept., Monroe, Louisiana*

Visual qualitative research methods are gaining more popularity among the social sciences. Photovoice involves individuals identifying and representing issues of interest through photos. This technique has primarily been used among diverse populations (e.g., homeless, Native Americans, etc.) by researchers to involve the public as stakeholders in community issues. This technique is ideally suited for use with economically and/or socially disadvantaged individuals in representing their concerns and giving them a voice. Additionally, the technique is invaluable for use with individuals who have limited education or literacy problems who might otherwise have difficulty in expressing their needs in verbal or written formats. Economically disadvantaged rural elders in northeast Louisiana were given cameras and asked to photographically represent regional and health issues and concerns they had for their community. Analyses indicated that this was a powerful technique which provided very informative data among the poorest, isolated elders in the US.

## SESSION 765 (SYMPOSIUM)

### ADMINISTRATION ON AGING'S COMMUNITY INITIATIVES: WHERE WE HAVE BEEN AND WHERE WE ARE GOING

Chair: *L. Alecxih, The Lewin Group, Falls Church, Virginia*
Co-Chair: *J. Lugo, Administration on Aging, Washington, District of Columbia*
Discussant: *C. Gruman, The Lewin Group, Falls Church, Virginia*

Funded by the US Administration on Aging (AoA), the Aging and Disability Resource Center (ADRC), the Community Living Program, and the Veteran's Directed Home and Community Based Services initiatives support the goals that state agencies, community organizations and advocates are working toward in many states - to make the long term service system more person-centered and consumer-directed, make it easier for people with disabilities of all ages to access information about home and community-based alternatives to institutional services, and support people of all income levels to live independently in their communities. Inspired by demonstrated state success and codified in the Older Americans Acts 2006 reauthorization, these programs support states in identifying innovative, cost-effective strategies for modifying state long term care systems, designing flexible programs that respond to the needs and preferences of individuals and families, and targeting services to individuals at risk for institutional placement so they can remain at home or in community settings. The AoA and the Centers for Medicare & Medicaid Services originally funded 43 states and territories to develop ADRC programs between 2003-2005. In September 2009, $11 million in grants were awarded to 49 states and territories to implement or expand the ADRC Program. Including several state representatives on the panel will allow for a diverse exchange of information about the strengths and weaknesses of the current system including: agency adaptation to consumer directed models, leveraging existing resources, managing systems faced with extreme fiscal constraints, evaluation strategies, and outcomes for all three programs.

### CASH AND COUNSELING: EVALUATION METHODOLOGY AND POLICY ISSUES

N. Shugrue[1], J. Robison[1], I.C. Reed[1], M. Morton[2], *1. University of Connecticut Center on Aging, Farmington, Connecticut, 2. Connecticut Department of Social Services, Hartford, Connecticut*

Connecticut has implemented its cash and counseling program through two caregiver respite programs. An independent longitudinal evaluation was conducted via telephone interview. Caregivers choosing cash and counseling and a comparison group of caregivers choosing traditional agency services are surveyed at baseline, three months, and program discharge. Topics include satisfaction, unmet need, depression, caregiver burden and benefits, and likelihood of nursing facility admission. Twenty months of data show few statistically significant differences between the groups. Both groups report high satisfaction and similar levels of depression, burden and unmet need. A large percentage of both groups indicate a high likelihood that the care recipients would have entered a nursing home without these services. After piloting the program, permanent expansion of cash and counseling program features were instituted legislatively. However, the state budget crisis threatens the progress made in enhancing individual autonomy and choice.

### MASSACHUSETTS' ADRCS AS COMMUNITY FOCAL POINTS FOR LONG TERM SERVICES AND SUPPORTS SYSTEMS CHANGE: EXPERIENCES AND POLICY IMPLICATIONS

H. Johnson, R. Palombo, *MA Executive Office of Elder Affairs, Lunenburg, Massachusetts*

Massachusetts was one of the pioneer states to implement the AoA-funded Aging and Disability Resource Center grant in 2003. Since then, the ADRCs continue to evolve as a central focal point for new State initiatives and systems change activities. ADRCs are now integrally linked to the implementation of the AoA-funded Community Living Program and Veterans-Directed Home and Community-Based Care initiatives, and are also pilot sites for two State-funded initiatives: Long Term Care Options Counseling and Consumer-Directed Service Options within State-funded home care programs. Within the two pilot projects, consumer satisfaction and agency experience data is being tracked and analyzed to support statewide expansion. This session will highlight both the practical program level lessons learned through data analysis as well as state-level policy implications in furthering the role of the ADRCs serving as community catalysts for systems change and consumer-directed options.

### THE VETERAN DIRECTED HOME AND COMMUNITY BASED SERVICE PROGRAM: A MULTI-STATE PERSPECTIVE

C. Gruman, L. Alecxih, *The Lewin Group, Falls Church, Virginia*

Beginning in 2008, the AoA began a collaboration with the Veterans Health Administration to serve Veterans of all ages at risk of nursing home placement. The VDHCBS program provides veterans the opportunity to self-direct their long-term supports and services. Veterans enrolled in this program have the opportunity to manage their own flexible budgets, to choose a mix of goods and services that best meet their needs, and to hire and supervise their own workers. Currently, 341 veterans are receiving services through the new program. This session will explore experiences with consumer direction, outcomes, programmatic challenges, individual case studies, and future directions.

## SESSION 770 (SYMPOSIUM)

### AN UPDATE ON RESEARCH ABOUT HIRING RELATIVES AS CAREGIVERS: MOVING BEYOND MYTHS AND ASSUMPTIONS

Chair: *L. Simon-Rusinowitz, School of Public Health, University of Maryland, College Park, Maryland*

Co-Chair: *K.J. Mahoney, Boston College, Chestnut Hill, Massachusetts*

Discussant: *P. Doty, US DHHS ASPE, Washington, District of Columbia*

While some publicly-funded community-based personal care programs have allowed consumers to hire relatives as caregivers for decades, this policy option remains controversial. Policy decisions about this option have often been based on myths and assumptions; however, there is a growing body of research to better inform these decisions. With increased interest in consumer-directed services (CD), which allow consumers to choose their caregivers, an option to hire relatives as caregivers has become a key part of personal care services. Some option supporters view it as one solution to worker shortages and possibly a means of cost saving. The Cash and Counseling Demonstration and Evaluation (CCDE), provided extensive data and experience from three CD state Medicaid programs. The majority of CD consumers hired relatives as caregivers. Research about the California In-Home Supportive Services (IHSS) program, a large, long-standing CD personal care program with many paid family workers, can also inform policymakers about this option. Lori Simon-Rusinowitz will begin the symposium with an historical overview about this policy option and a synthesis of CCDE findings on this topic. Next, Sara Moorman will present new findings about the association between CCDE family caregiver pay status and the consumer/ caregiver relationship. Robert Newcomer will present IHSS program findings comparing relatives and non-relatives as providers among racial/ethnic groups, including health care use by caregiver group. Kathryn Kietzman will present findings from a study about the perceived choice that ethnically diverse IHSS family caregivers have in assuming paid roles. Lori Simon-Rusinowitz and Pamela Doty will be discussants.

### PAYING FAMILY CAREGIVERS: ASSOCIATIONS WITH STRAIN AND CAREGIVER/CARE RECIPIENT RELATIONSHIP QUALITY

S.M. Moorman[1], D.M. Loughlin[2], L. Simon-Rusinowitz[2], *1. Sociology, Boston College, Chestnut Hill, Massachusetts, 2. University of Maryland, College Park, Maryland*

While most family caregivers in the United States are unpaid, in states where it is implemented, the Cash and Counseling program allows Medicaid recipients to pay family caregivers. We investigate the associations among pay status, caregiver strain, and caregiver/care recipient relationship quality in a sample of 1,699 family caregiver/care recipient dyads residing in Arkansas, Florida, and New Jersey. We find that paid family caregivers report higher levels of relationship quality than do informal family caregivers. This association is mediated by level of strain: Paid family caregivers report lower levels of strain than do informal family caregivers, and lower strain is associated with better relationship quality. However, the paid and unpaid groups are comprised of different relations. For example, grandchildren and spouses each comprise about 7% of informal caregivers, but among paid caregivers, 15% are grandchildren and less than 1% are spouses. We discuss implications for policy.

### HIRING RELATIVES AS CAREGIVERS: WHAT DID WE LEARN FROM CASH AND COUNSELING?

L. Simon-Rusinowitz[1], D.M. Loughlin[1], K.J. Mahoney[2], *1. University of Maryland, College Park, Maryland, 2. Boston College, Chestnut Hill, Massachusetts*

While some publicly-funded community-based personal care programs have allowed consumers to hire relatives as caregivers for decades, this policy option remains controversial. Policy decisions about this option have often been based on myths and assumptions; however, there is a growing body of research to better inform these decisions. This presentation will discuss early research about this topic and findings from the Cash and Counseling Demonstration and Evaluation (CCDE), a consumer-directed option in which the majority of consumers hired relatives. We will synthesize findings on this topic from the original CCDE; a secondary analysis of family and non-family caregivers in Arkansas; focus groups with paid workers in three CCDE states; and a two-state case study of stakeholders' views about this policy option. This presentation will provide background information for the other presentations.

### ALLOWING SPOUSES TO BE PAID HOME CARE PROVIDERS: EFFECTS ON MEDICAID-FUNDED SERVICE USE AND COSTS

R. Newcomer[1], T. Kang[1], P. Doty[2], *1. University of California, San Francisco, California, 2. Office of the Assistant Secretary for Planning & Evaluation, Washington, District of Columbia*

Analyses investigated whether recipients in California's In Home Supportive Service (IHSS) program who used a spouse as a paid personal assistance provider had at least comparable health care use and nursing home placement outcomes compared to recipients having other paid providers. Medicaid claims and assessment data for all recipients age 18 or older in 2005 (n=330,392) were used. There was no financial disadvantage and some advantages to Medicaid in terms of lower average Medicaid expenditures and fewer nursing home admissions, and similar hospitalization rates comparing recipients having spouses, parents, or other relatives as paid IHSS providers with recipients using non-relatives. This argues in favor of honoring the recipient's and family's preference for such providers. This research was supported by the Office of the Assisted Secretary for Planning & Evaluation, Department of Health & Human Services; and the National Institute for Disability and Rehabilitation Research.

### PAID FAMILY AND FRIEND CAREGIVERS: HAVING A CHOICE TO PROVIDE CULTURALLY RESPONSIVE CARE

K.G. Kietzman[1,2], A. Benjamin[3], R.E. Matthias[3], *1. Partners in Care Foundation, San Fernando, California, 2. Health and Aging Policy Fellow, Washington, District of Columbia, 3. UCLA School of Public Affairs, Los Angeles, California*

This mixed method study focuses on the experiences of family and friend caregivers who are paid to provide personal care services to Medicaid-eligible disabled and elderly through California's In-Home Supportive Services program. While much discussion about consumer-directed care has focused on the self-determination of care recipients, this study investigates the perceived choice that related caregivers have in assuming these paid caregiver roles. We find that caregiver perception of choice is rooted in a wide array of cultural and gender norms and is quite variable, both within and across cases. Among this ethnically diverse sample of family and friend caregivers, these norms appear to influence their initial assumption of the paid caregiver role and the ways in which they subsequently construct and manage these care arrangements. The findings indicate that related caregivers are often well positioned to provide culturally appropriate care that is responsive to both care recipient and caregiver preferences.

## SESSION 775 (PAPER)

## ECONOMICS OF AGING

### THE EFFECTS OF MEDICARE DRG PAYMENTS ON THE QUALITY OF HOSPITAL CARE

J. Huang, G.A. Jensen, *Wayne State University, Detroit, Michigan*

BACKGROUND: Concerns about the soaring costs of Medicare have dominated recent discussions about how to reform this program so that spending is better-controlled. Medicare's hospital DRG payment schedule is an important tool legislators have available to limit program spending. Yet, little is known about the nature of the gradient between hospital care quality and what Medicare pays for specific DRGs. This study examines this issue empirically for hospital stays with a diagnosis of pneumonia, which are relatively common under Medicare. METHODS: We first develop a theoretical model, which generates the key hypothesis — that Medicare payment is positively related to quality. We then test this empirically by estimating the relationship between Medicare's DRG payment for pneumonia and the quality of pneumonia care, using seven different clinically-recognized measures of quality. Data on more than 3000 U.S. acute hospitals observed in 2007 fiscal year from the "Hospital Compare" data base maintained by CMS are used for this analysis, and were linked with data from the Healthcare Cost Report Information System, the Hospital Impact File maintained by CMS, and the Area Resource File maintained by the Bureau of Health Professions. RESULTS AND IMPLICATIONS: Six of the seven quality measures are positively and significantly related to Medicare's pneumonia DRG payment. Although we find a gradient between payment and quality, it is rather small for most measures examined. This is evidence that hospital quality of care for pneumonia admissions would suffer, but only by a very small amount, if Medicare DRG payments for pneumonia were reduced.

### TAPPING HOME EQUITY FOR LONG-TERM CARE EXPENSES: EVIDENCE FROM THE HEALTH AND RETIREMENT SURVEY

D.L. Redfoot, L. Walker, *AARP Public Policy Institute, Washington, District of Columbia*

Home equity is the primary asset for most older homeowners, but most evidence indicates that it is a largely untapped asset. Most older homeowners indicate no interest in accessing their home equity to use as an income supplement – as evidenced by the fact that less than 2 percent of older homeowners have taken out a reverse mortgage despite the high proportion of elderly homeowners who are income-poor and housing-rich. Older homeowners appear more willing to tap home equity to deal with major life crises. In particular, some evidence suggests that older homeowners are using home equity to pay for long-term care services, especially for private pay options like assisted living. In this presentation, we use data from the Health and Retirement Survey (HRS) to explore the extent to which elderly homeowners draw-down home equity and other assets after experiencing major changes in disability status. Using the panel nature of the HRS, we can observe how household asset levels (we look at a number of asset measures) change before and after the incidence of a major change in disability status. We can observe changes in housing location and housing choices (such as housing offering services) associated with a significant increase in disability. From these patterns, we can begin to infer the degree to which older homeowners are using home equity to fund long-term care services. Such research can begin to fill important policy-related knowledge gaps about the degree of private financing of long-term care.

### RELATIVE INCOME AND MOONLIGHTING BY PRE-AND POST-RETIREMENT AGE WORKERS

L.H. Nitz, *Political Science, University of Hawaii, Honolulu, Hawaii*

A stream of research in behavioral economics attempts to trace satisfaction and its correlates to either absolute income level or a comparison of own income to that of some reference group. By one interpretation, work is one of the sources of life satisfaction. The absolute income hypothesis suggests that people with less income are more likely to moonlight to raise their aggregate income. The relative income hypothesis suggests that having low income relative to an important reference group is a motivator for additional work—for the purpose of restoring a sense of equity. The 2004 panels of the Survey of Income and Program Participation has 15857 individuals near and post retirement age. For most of these individuals there are twelve repeated measures of consecutive months of employment data. Dividing the population into older and younger cohorts allows a test of relative income predictions. The GEE estimate of the older group (-4.15, p.10) shows lower moonlighting income than the younger group. The interaction between income ratio and age is -2,69 (p.035) indicating that younger workers moonlight more when relative income is low, but older workers do not. Absolute income has a positive association with moonlighting, contrary to expectation.

## SESSION 780 (SYMPOSIUM)

### THE NATIONAL BALANCING INDICATOR CONTRACT: MEASURING STATES' EFFORTS TOWARD A PERSON-CENTERED SYSTEM OF LONG-TERM SERVICES AND SUPPORTS

Chair: *O. Urdapilleta, IMPAQ International, LLC, Columbia, Maryland*
Co-Chair: *T. Moore, Abt Associates Inc., Cambridge, MA, Massachusetts*
Discussant: *S.A. Flanagan, Westchester Consulting Group, Washington, District of Columbia*

As states reform their long-term support systems (LTSS), there is a growing interest in determining their successes in attaining and maintaining person-centered care, and an adequate mix in the provision of Medicaid institutional care and community-based services and related expenditures. These issues continue to be critical components of federal and state level discussions on the current state of and future for LTSS. This symposium presents the work of the National Balancing Indicator Contract (NBIC) assisting the Centers for Medicare & Medicaid Services (CMS) and states to develop a set of indicators measuring states' progress in offering LTSS. Papers highlight the development and testing of LTSS indicators achieved through collaboration with CMS, 10 State Profile Tool (SPT) grantees, a technical expert panel and a wide range of key stakeholders. Despite substantial research efforts studying LTSS, there remains a gap in the availability of common indicators to measure measures of individual choice, control and access of the full array of LTSS. The first paper presents a conceptual framework and principles that guided the NBIC in the development of the LTSS indicators. The second paper describes the processes through which a larger set of indicators were narrowed, operationalized, and vetted by CMS, SPT grantees, national experts and stakeholders and the third paper presents results of baseline data collected from SPT grantees.

### SUSTAINABLE AND PERSON-CENTERED: THE LONG-TERM SUPPORT SYSTEM OF THE FUTURE

T. Moore[1], O. Urdapilleta[2], M. Eastman[1], D. Walker[1], *1. Abt Associates Inc., Cambridge, Massachusetts, 2. IMPAQ International, LLC, Columbia, Maryland*

The National Balancing Indicator Contract (NBIC) is assisting the Centers for Medicare & Medicaid Services (CMS) to develop and test national indicators to assess states' efforts to attain a person-driven long-term support systems (LTSS). Part of the work of the NBIC has been to develop a vision and conceptual framework for the future of the LTSS, in order to subsequently measure the performance of that system. The NBIC's framework represents a departure from former notions of "rebalancing," in that we focus more broadly on a system that is "person-driven", provides full access to community alternatives, and is responsive to the needs and desires of individuals. In this presentation the conceptual framework for the NBIC will be presented, along with findings that indicated the need to develop an entirely new set of performance indicators to estimate state-level efforts at achieving person-centered, sustainable LTSS.

### DEVELOPING INDICATORS TO MEASURE PROGRESS AND SUCCESS IN LONG-TERM SUPPORT SYSTEMS

L. Clark[1], T. Moore[2], O. Urdapilleta[1], M. Eastman[2], *1. IMPAQ International, LLC, Columbia, Maryland, 2. Abt Associates Inc., Cambridge, Massachusetts*

The National Balancing Indicator Contract (NBIC) was tasked with determining a set of indicators that specify states' progress in providing a person-centered, person-driven long-term supports system (LTSS). The LTSS indicators were developed through extensive review and selection of existing measures in conjunction with the development of novel measurements. Each indicator was then vetted through a panel of technical experts, representatives from State Profile Tool (SPT) Grantees, and stakeholders ranging from national associations to consumer advocates. The final set of indicators represents the LTSS principles of sustainability, self-determination, community integration, shared accountability, prevention, and coordination and transparency. This paper presents the rationale for selection, key measurement concepts, data specifications, and operationalization of each indicator. In addition, challenges faced by the NBIC in developing the set of indicators and strategies used to overcome these challenges will be discussed.

### RESULTS FROM THE NATIONAL BALANCING INDICATOR CONTRACT BASELINE DATA COLLECTION

O. Urdapilleta[1], T. Moore[2], L. Clark[1], M. Eastman[2], *1. IMPAQ International, LLC, Columbia, Maryland, 2. Abt Associates Inc., Cambridge, Massachusetts*

The National Balancing Indicator Contract (NBIC) collaborated with 10 State Profile Tool (SPT) grantees to collect data on states' progress in offering person-centered, person-driven long-term supports and services (LTSS). Data from SPT grantee states were collected on 15 LTSS indicators, representing sustainability, self-determination, community integration, shared accountability, prevention, and coordination and transparency. Indicators were classified per type of indicator: a baseline measure of current state in the corresponding LTSS indicator or a benchmark/target measure of states' progress toward optimal LTSS characteristics. This paper will first present the scoring methodology for selected indicators, followed by state-specific results. Issues relevant to across-state comparisons will then be discussed, including the feasibility and validity of comparing LTSS given variance in Medicaid state policies and other state characteristics influencing long-term care delivery. Finally, implications for future data collection efforts using the LTSS indicators will be discussed.

## SESSION 785 (SYMPOSIUM)

### TRANSITIONING NURSING HOME RESIDENTS DURING HURRICANE EMERGENCIES—THE MORBIDITY AND MORTALITY CONSEQUENCES OF EVACUATION VERSUS SHELTERING IN PLACE DURING HURRICANES KATRINA, RITA, GUSTAV AND IKE

Chair: *D. Dosa, Medicine, Brown University, Providence, Rhode Island, Providence VAMC, Providence, Rhode Island*
Co-Chair: *K. Hyer, University of South Florida, Tampa, Florida*
Discussant: *H. Moody, American Association of Retired Persons, Washington DC, District of Columbia*

The devastating effects of Hurricane Katrina on the Gulf Region highlighted the importance of emergency preparedness and cast a sharp media spotlight on nursing homes (NHs) such as St. Rita's that failed to evacuate their residents prior to the storm. Four weeks later, the most resounding image of Hurricane Rita was the burned out bus where 23 NH evacuees lost their lives. To date, a central unanswered question remains. Is it better to evacuate or shelter in place when it comes to frail NH residents? In this symposium we will present 5 papers designed to answer this question. Using data from the last four major Gulf hurricanes (Katrina, Rita, Gustav, and Ike), Paper 1 will present the cumulative consequences of the storms on NH residents in terms of mortality, hospitalizations, and functional decline. Paper 2 will present mental health consequences from the storms. Paper 3 will address qualitative data from NH directors contrasting the preparedness for evacuations in 2005 versus 2008. Paper 4 will identify facility level predictors of the decision to evacuate. Finally, Paper 5 will identify the consequences of evacuation versus sheltering in place. Two discussants will participate in this symposium: Harry Moody is the Director of Academic Affairs for the American Association of Retired Persons (AARP) and Joe Donchess is the Executive Director of the Lousiana Nursing Home Association. After attending this activity, participants will have an understanding of the consequences of evacuation versus sheltering in place and will be able to define predictors of evacuation.

### THE MORTALITY AND MORBIDITY CONSEQUENCES OF HURRICANES KATRINA, RITA, GUSTAV, AND IKE ON NURSING HOME RESIDENTS

K. Hyer[1], D. Dosa[2], L.M. Brown[1], Z. Feng[2], K.S. Thomas[1], V. Mor[2], *1. School of Aging Studies, University of South Florida, Tampa, Florida, 2. Brown University, Providence, Rhode Island*

Introduction: Two hurricanes in 2005 (Katrina, Rita) later followed by two hurricanes in 2008 (Gustav and Ike) ravished the Gulf Coast. This paper compares and contrasts the mortality and morbidity of nursing home (NH) residents in the Gulf Region for all four storms. Methodology: We compare the 30 and 90 day mortality and morbidity rates (e.g. hospitalizations, functional decline) of NH residents exposed to the hurricanes and compare it with control data from the same NHs in the two years prior to the storm. Mortality, Hospitalization rate, and Functional decline outcomes were ascertained using data from either the Minimum Data Set (MDS) and/or Medicare claims. Results: Thirty and 90 day mortality, hospitalization rate, and functional decline increased ($p<0.05$) for all residents exposed to Hurricanes Katrina or Rita. By modeling Gustav and Ike we can compare the morbidity and mortality rates of 2008 storms to those of 2005.

### NEEDS OF NURSING HOME RESIDENTS FOR DISASTER MENTAL HEALTH SERVICES

L.M. Brown[1], K. Hyer[1], L. Polivka-West[2], *1. Aging and Mental Health Disparities, University of South Florida, Tampa, Florida, 2. Florida Health Care Association, Tallahassee, Florida*

A mixed-methods study was conducted to evaluate residents' pre- and post-hurricane mental health service use in Gulf region nursing homes (NHs). A questionnaire was administered to 258 NHs to identify residents' disaster mental health needs and staffs' interest and ability to provide services. In four subsequent focus group meetings with 22 NH administrators, underlying factors influencing residents' use of services were evaluated. Although most facilities provided some form of mental health care during normal operations, disaster-related mental health services were not routinely provided. Half of the respondents indicated interest in offering residents a pre-disaster, resilience-building intervention and also psychological first aid post-disaster. Approximately 10% indicated that they didn't have access to mental health clinicians to deliver disaster mental health interventions. Respondents felt that NH staff could be trained to deliver psychological first aid and in procedures for making referrals for follow-up evaluation.

### COMPARING NURSING HOME ADMINISTRATOR PERCEPTIONS OF EMERGENCY PREPAREDNESS BETWEEN HURRICANES KATRINA (2005) AND GUSTAV (2008)

D. Dosa[1,2], G. Blanchard[3], L.M. Brown[4], K. Hyer[4], V. Mor[1], *1. Medicine, Brown University, Providence, Rhode Island, 2. Providence VAMC, Providence, Rhode Island, 3. Saint Vincent's Hospital, Worchester, Massachusetts, 4. University of South Florida, Tampa, Florida*

Introduction: This paper qualitatively describes perceptions of Louisiana nursing home (NH) administrators (ADs) who experienced both Hurricanes Katrina (2005) and Gustav (2008) to elicit whether facility preparedness improved. Methodology: ADs who participated in a series of qualitative telephone interviews to evaluate their lessons learned from Katrina were contacted after Gustav to compare preparedness. Specifically, ADs were asked about issues with evacuation (e.g., transportation, injuries) and to rate their confidence with state assistance and their evacuation preparedness. Results: 16 of the 20 NHs that participated in 2005 agreed to be surveyed. Unlike Katrina, when only 45% evacuated, 100% evacuated before Gustav. Overall, ADs rated their confidence in preparedness for Gustav as a mean of 8.4 (range 5-10) – compared to 5.7 (range 3-8) for Katrina, a 47% improvement. Additionally, 80% reported improved collaboration with the state. Perception of improvement by ADs will be contrasted with outcomes data presented in Paper 1.

### PREDICTORS OF NURSING HOME EVACUATION—WHAT FACTORS DO NURSING HOME ADMINISTRATORS CONSIDER?

K.S. Thomas[1], D. Dosa[2], K. Hyer[1], L.M. Brown[1], Z. Feng[2], V. Mor[2], *1. School of Aging Studies, University of South Florida, Tampa, Florida, 2. Brown University, Providence, Rhode Island*

Introduction: This paper describes the predictors for nursing home (NH) evacuation for the four most recent hurricanes to affect the Gulf Region (Katrina, Rita, Gustav and Ike). Methodology: NHs were geocoded and the facility's distance from the storm's center was calculated at 24, 48, and 72 hours prior to landfall based on National Hurricane Center forecasts. Additional factors considered were the NHs elevation, and distance to the shoreline. Demographic factors and the facility-level rates of certain illnesses (e.g. heart failure, COPD, etc.) were also considered. All factors were placed in a multivariate Probit model. Results: The largest predictor of evacuation was the distance of the facility to the storm at 48 hrs (Z coefficient=-9.43; $p<0.005$). Being west of the storm at 48 hrs was predictive of sheltering in place (Z=-4.46; $p<0.005$). Patient demographics (e.g. race, gender, age) and the relative burden of illness were not predictive of the evacuation decision.

### ARE WE DOING THE RIGHT THING BY EVACUATING NURSING HOME RESIDENTS? THE EFFECT OF EVACUATION ON RESIDENT MORTALITY AND MORBIDITY

V. Mor[1], D. Dosa[1,2], L.M. Brown[3], K.S. Thomas[3], Z. Feng[1], K. Hyer[3], *1. Medicine, Brown University, Providence, Rhode Island, 2. Providence VAMC, Providence, Rhode Island, 3. University of South Florida, Tampa, Florida*

Introduction: This paper describes the effects of evacuation versus sheltering in place on nursing home (NH) residents during the last 4 major Gulf storms (Katrina, Rita, Gustav, and Ike) Methodology: Demographic variables (age, gender, race), patient level comorbidities (e.g. CHF, Cancer, COPD, Renal Failure, etc), and facility level variables (e.g. decision to evacuate, Medicaid rate, Payment mix, etc.) were considered in a Probit multivariate regression. An instrumental variable approach was utilized to control for biases related to unmeasured factors. Results: For both Hurricanes Katrina and Rita, the effect of evacuation independent of storm factors resulted in a statistically significant increase in death at 30 days (Z=2.88; p=0.004) that was greater than the effects of patient specific diagnoses such as CHF (Z=2.74; p=0.006) and Cancer (Z=2.29; p=0.02). Hospitalization rates were similarly affected by evacuation. Data from 2008 storms will be available this spring and will complete the analysis.

## SESSION 790 (POSTER)

## BIOLOGICAL SCIENCES POSTER SESSION

### SENESCENCE-RELATED FUNCTIONAL NUCLEAR BARRIER BY DOWN-REGULATION OF NUCLEO-CYTOPLASMIC TRAFFICKING GENE EXPRESSION

S. Kim, H. Kang, H. Choi, K. Lee, S. Park, *Biochemistry, Seoul national university College of medicine, Seoul, Seoul, Republic of Korea*

One of the characteristic natures of senescent cells is the hypo- or irresponsiveness not only to growth factors but also to apoptotic stress. In the present study, we confirmed the inhibition of nuclear translocation of activated p-ERK1/2 and NF-kB p50 in response to growth stimuli or LPS in the senescent human diploid fibroblasts. In order to elucidate the underlying mechanism for the senescence-associated hypo-responsiveness, we carried out the comparison study for gene expression profiles through microarray analysis. In consequence, we observed the vast reduction in expression of nucleo-cytoplasmic trafficking genes in senescent cells, when compared with those in young cells. Expression levels of several nucleoporins, karyopherin α, karyopherin β, Ran, and Ran-regulating factors were confirmed to be down-regulated in senescent HDFs by using RT-PCR and Western blot methods. Taken together, these data suggest the operation of certain senescence-associated functional nuclear barriers by down-regulation of the nucleo-cytoplasmic trafficking genes in the senescent cells.

## CIRCULATING RENIN ANGIOTENSIN SYSTEM BIOMARKERS AND COGNITIVE FUNCTION IN HYPERTENSION WITH COGNITIVE IMPAIRMENT

I. Hajjar[1,2,3], M. Hart[3], W. Milberg[1,4], L. Lipsitz[1,2,3], *1. Harvard Medical School, Boston, Massachusetts, 2. Beth Israel Deaconess Medical Centre, Boston, Massachusetts, 3. Institute for Aging Research, Hebrew SeniorLife, Boston, Massachusetts, 4. GRECC VA Boston Healthcare, Boston, Massachusetts*

Hypertension is associated with cognitive impairment especially in the executive function domain. Evidence from animal models suggests that the renin angiotensin system (RAS) plays a role in cognitive function. We aimed at studying the association between circulating markers of RAS and cognitive function in elderly hypertensives with early cognitive impairment. Participants (n=47, 71.2 years, 60% women, 28% African Americans, 86% on treatment) were enrolled in the antihypertensives and vascular, endothelial, and cognitive function (AVEC) trial. We measured plasma renin activity (PRA) and aldosterone at baseline. Those receiving antihypertensives had their medications tapered off (3-4 weeks). A blood specimen was collected during the baseline visit using standard procedure. Cognition was assessed using (executive clock draw (CLOX1), Hopkins Verbal learning Test (HVLT) and forward and backward Digit Span test (DST). After adjusting for demographics, education, body mass index and blood pressure, higher circulating aldosterone was associated with lower CLOX1 scores (beta=-0.2±0.1; p=0.04) and lower HVLT score (beta=-0.15±0.06, p=0.02). Further, aldosterone to PRA ratio was associated with lower HVLT score (beta=-0.09±0.04;p=0.02). Further adjustment to antihypertensives did not affect the results. DST was not associated with RAS biomarkers. This study suggests that greater RAS activity, reflected by higher biomarkers, is associated with worse executive cognitive function and memory in elderly hypertensives with early cognitive decline.

## ACTIVATION OF THE JAK/STAT SIGNALING PATHWAY AND CARDIOMYOCYTE RESPONSE TO OXIDATIVE STRESS

G. Azhar[1], A.M. Borras[2], X. Zhang[1,3], G.O. Johnson[1], J.Y. Wei[1,3], *1. Geriatrics, UAMS, Little Rock, Arkansas, 2. Harvard Medical School, Boston, Massachusetts, 3. CAVHS, GRECC, Little Rock, Arkansas*

Background: Cardiovascular disease is the number one cause of morbidity and mortality in the aging population. Oxidative stress-induced damage plays a central role in the pathogenesis of several cardiac diseases and the molecular response to oxidative stress is of increasing interest. We sought to determine whether members of the Janus kinases (JAK) and signal transducers and activators of transcription (STAT) family are activated in response to hydrogen peroxide and simulated ischemia-reperfusion in cardiac muscle cells. Methods: Rat primary cardiomyocytes and H9C2 cells were exposed to oxidative stress conditions mediated by using varying concentrations of hydrogen peroxide. A simulated ischemia-reperfusion chamber was also induced to the stress of ischemia and then reoxygenation. in primary cardiomyocytes. Results: Exposure to hydrogen peroxide resulted in a rapid and significant increase in tyrosine phosphorylation of JAK2, STAT1 and STAT3 in both H9C2 and primary cardiomyocytes. Simulated ischemia alone did not activate the JAK-STAT proteins, but ischemia followed by reperfusion caused rapid tyrosine phosphorylation of JAK2, STAT1 and STAT3. This phosphorylation was inhibited by catalase. The phosphorylated STAT1 and STAT3 bound specifically to the DNA cognate sequence known as the sis-inducible element (SIE). Inhibition of JAK2 decreased the phosphorylation of STAT3 but not STAT1. Conclusion: These results demonstrate that oxidative stress, especially reperfusion activates the JAK/STAT pathway in cardiomyocytes, via JAK2-STAT 3 signaling. The induced signaling via the JAK/STAT pathway may play an important role in cardiac cell injury or repair in hearts of older individuals who are more vulnerable to oxidative stress.

## ANTIOXIDANT EFFECT OF 4,4'-DIAMINODIPHENYLSULFONE AGAINST OXIDATIVE STRESS IN HUMAN DIPLOID FIBROBLASTS

S. Cho, J. Rhim, Y. Son, S. Lee, S. Park, *Department of Biochemistry and Molecular Biology, Seoul National University College of Medicine, Seoul, Republic of Korea*

4,4'-diaminodiphenylsulfone (DDS), an old antibiotic drug, is used in treating several dermatologic diseases, including Hansen's disease. Despite its long term use, the debate on its nature of antioxiative or prooxidative effects has been continued. In this study, we tested the effect of DDS as an antioxidant on paraquat (PQ) or hydrogen peroxide (H2O2)-induced oxidative stress in human diploid fibroblasts (HDFs). Preincubation of HDFs with DDS prevented the cytotoxic damages in a dose-dependent manner otherwise caused by PQ or H2O2-induced oxidative stress. . The specific effects of DDS in PQ or H2O2 treated HDFs are summarized as follows: a) in PQ-induced oxidative stress, DDS reduced the expression of NADPH oxidase 4 (NOX4) via inhibiting PQ-induced activation of protein kinase C (PKC), and also DDS effectively adjusted the PQ-induced abnormality in mitochondrial complex protein levels, membrane potentials and superoxide generation in HDFs; b) in H2O2-induced oxidative stress, DDS increased the levels of catalase (CAT), glutathione peroxidase (GPx) and glutathione reductase (GR) activities, and also the GSH/GSSG ratio, indicating the activation of glutathione system against oxidative stress. Taken together, it can be concluded that DDS can be a good antioxidant against PQ or H2O2-induced oxidative stress in HDFs in addition to its antibiotic function and might serve as a potential tool in prevention of oxidative stress-related pathologies.

## PREDICTORS OF 16α-HYDROXYESTRONE, AN ESTROGEN METABOLITE ASSOCIATED WITH LOWER BLOOD PRESSURE

C. Masi, S.A. Patel, L. Hawkley, J.T. Cacioppo, *University of Chicago, Chicago, Illinois*

We recently identified an inverse relationship between systolic blood pressure (SBP) and serum 16α-hydroxyestrone, a metabolite of 17β-estradiol, in postmenopausal women. Formation of 16α-hydroxyestrone is catalyzed primarily by the cytochrome P450 enzyme, CYP1A2. The goal of this study was to evaluate the relationships between known modifiers of CYP1A2 activity and serum 16α-hydroxyestrone in postmenopausal women. We hypothesized that dietary fiber from fruits and vegetables (a known inducer of CYP1A2) would be more positively associated with serum 16α-hydroxyestrone than dietary fiber from grains and legumes, which tend to have less soluble fiber. We used ordinal logistic regression to evaluate the cross-sectional relationship between dietary and demographic factors and serum 16α-hydroxyestrone concentration in a population-based sample of 42 postmenopausal women aged 55-69 living in Cook County, Illinois. Relative to dietary fiber from grains and legumes, dietary fiber from fruits and vegetables was associated with a greater log odds (B = 0.201, p = 0.036) of having a higher serum concentration of 16α-hydroxyestrone after adjusting for multiple covariates. In contrast, the log odds of having a higher serum concentration of 16α-hydroxyestrone was lower among African-American women (B = -2.300, p = .030) compared to white women. These results are consistent with previous studies demonstrating an inverse relationship between SBP and dietary fruits and vegetables and a positive relationship between SBP and African-American race. Further research is needed regarding dietary and behavioral factors that may influence $16\alpha$-hydroxyestrone production, as well as the potential mechanisms by which serum $16\alpha$-hydroxyestrone is associated with race.

### A SINGLE BOUT OF AEROBIC EXERCISE RESTORES THE ANABOLIC EFFECT OF MIXED FEEDING IN OLDER ADULTS

K.L. Timmerman, S. Dhanani, E.L. Glynn, C.S. Fry, M.J. Drummond, B.B. Rasmussen, E. Volpi, *Sealy Center on Aging, University of Texas Medical Branch, Galveston, Texas*

Skeletal muscle is resistant to the anabolic effects of both insulin and mixed feeding in older adults, in part due to endothelial dysfunction. Aerobic exercise restores the ability of insulin to induce vasodilation and stimulate muscle protein synthesis in older persons. However, it is unknown if it can also restore the anabolic response of muscle to mixed feeding. We used a randomized cross-over design to measure muscle protein kinetics (13C6-phenylalanine) and microvascular perfusion (contrast enhanced ultrasound) at baseline and during mixed meal ingestion (20g of essential amino acids + 35g of glucose) on 2 occasions: after rest or after a bout of aerobic exercise. We report preliminary data from 6 healthy, elderly subjects (age: 70±3 yr). Microvascular perfusion (Rest, basal: 0.48±0.18, meal: 0.45±0.21; Exercise, basal: 0.37±0.08, meal: 1.23±0.23 VI/sec) and mixed muscle protein synthesis (Rest, basal: 0.060±0.006, meal: 0.056±0.006; Exercise, basal: 0.055±0.004, meal: 0.072±0.009 %/h) increased ($P<0.05$) from baseline during mixed meal ingestion only after exercise, but not after rest. Amino acid delivery to the leg increased significantly ($P<0.05$) under both conditions (Rest, basal: 137±35, meal: 422±240; Exercise, basal: 129±15, meal: 664±107, nmol/min/100 ml leg), but the change was larger ($P<0.05$) after exercise. In conclusion, these preliminary data suggest that a prior bout of aerobic exercise restores the muscle protein anabolic effect of mixed feeding in older adults, possibly due to increased microvascular perfusion and amino acid delivery.

### THE SYSTEMIC CONSTRAINTS THEORY OF AGING: INTEGRATING EVOLUTIONARY AND MECHANISTIC APPROACHES

A.A. Cohen, *Groupe de Recherche PRIMUS, Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, Quebec, Canada*

The three current evolutionary theories of aging – Mutation Accumulation, Antagonistic Pleiotropy, and the Disposable Soma – all fail to adequately explain the diversity of lifespans and aging processes observed across species. There are many existing mechanistic theories, but no one has proposed a way to understand or integrate their relative importance or assess their roles. Here, I develop a theory of physiological systems that can be used to contextualize ideas such as allostatic load and homeostenosis. Many existing mechanistic theories are subsumed and integrated under this theory, including inflammation and free radical damage. The mechanistic idea is then extended to an evolutionary context, where it is proposed that macro-evolutionary forces such as inertia constraints and algorithm constraints may force trade-offs differentially on different taxa, such that within some taxa (such as mammals) aging rate and lifespan evolve as a result of trade-offs, but in other taxa (such as turtles) trade-offs are weak or non-existent. Macro-evolutionary patterns in aging and lifespan are thus attributed primarily to constraints, while micro-evolutionary patterns are attributed to natural selection and genetic drift according to the existing theories. This theory is the first to successfully integrate all levels of biological knowledge on aging, including biochemical, cellular, genetic, organismal, micro-evolutionary, and macro-evolutionary.

### HEALTHY AGING AND OBESITY RESISTANCE IN MICE LACKING THE CATALYTIC C BETA SUBUNIT OF PROTEIN KINASE A

L.C. Enns, H.B. Richards, K.L. Bible, W. Ladiges, *Comparative Medicine, University of Washington, Seattle, Washington*

Protein kinase A (PKA) plays a major role in the regulation of energy balance. Our previous studies showed that C57BL/6 mice lacking the $C\beta$ subunit of PKA ($C\beta$ null) are resistant to obesity, fatty liver and leptin insensitivity when fed a high calorie diet. We examined $C\beta$ null mice maintained on a regular diet, at 12 and 24 months of age. At 12 months, mutants had body fat percentages of 24% compared to 28% for WT females ($P=0.016$), and metabolic rates on average 7% higher in the mutants ($P<0.05$). At 24 months of age, 43% of WT littermates, but none of the mutants had body weights approaching 40% body fat. Healthy aging was observed in mutant hearts. At 24 months of age echocardiography showed that WT littermates had significantly higher Ea/Aa ratios, MPI, and fractional shortening and lower ventricular circulation times and aorta/left atrium ratios than $C\beta$ null mice. WT mice had enlarged hearts, 20% heavier than mutants ($P=0.024$). PKA cross talks with the AMPK (AMP-activated protein kinase) pathway, phosphorylating AMPK in response to leptin to stimulate fatty acid oxidation. Phosporylated AMPK also inactivates ChREBP, reducing transciption of enzymes involved in lipogenesis. We now have data to show that $C\beta$ null mice have increased levels of phosphorylated AMPK, and reduced levels of ChREBP, indicating that increased fatty acid oxidation and decreased lipogenesis through the AMPK pathway may be the mechanism by which PKA $C\beta$ disruption leads to obesity resistance and healthy aging.

### LONGEVITY AND METABOLISM OF SPONTANEOUS DWARF RAT (SDR)

T. Shinkai, S. Nomoto, *Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan*

Spontaneous Dwarf Rat (SDR), a dwarf rat strain derived from Sprague-Dawley (SD) rats, is an experimental model for pituitary dwarfism and has growth hormone (GH) deficiency. The body weight of SDRs reduces to one-third that of normal SD rats. The mean lifespan of SDRs were 29.3 +- 3.3 months in male and 26.8 +- 5.3 months in female. They were increased by 20-40% in males and 10-20% in females, comparing to the reported longevity data of SD rats. Hormones involved in metabolism showed low levels in SDRs. For instance the concentration of GH was significantly lower in SDRs than in SD rats. Both IGF-1 and insulin levels were also decreased compared to SD rats. The concentration of thyroxin showed 70% reduction from SD rat level. The circadian rhythm of core temperature was higher in nighttime and lower in daytime in both rats, on the other hand average core temperature was lower in SDRs (37.0 C) than in SD rats (37.7 C). Moreover, using a computed tomography scanner we found that SDRs were rich in subcutaneous fat. Our findings suggest that decrease metabolism may prolong the lifespan of SDRs, and that subcutaneous fat may regulate metabolism by prevention of heat diffusion. Therefore, SDRs, with different characters in longevity, metabolism and endocrinology, are considered to have a possibility of a new animal model for an aging research.

### SERUM GAMMA-GLUTAMYL TRANSFERASE HAS AN EFFECT ON HYPERTENSION PROGRESSION AMONG COMMUNITY-BASED ELDERLY POPULATION IN KOREA

J. Jeong[1], K. Hong[2], D. Kim[1,3], *1. Institute of Aging, Hallym University, Chuncheon, Gangwon, Republic of Korea, 2. Dept. of Internal Medicine, Hallym University, Chuncheon, Gangwon, Republic of Korea, 3. Dept. of Social and Preventive Medicine, Hallym University, Chuncheon, Gangwon, Republic of Korea*

Serum gamma-glutamyl transferase(GGT), clinical marker for excessive alcohol consumption and oxidative stress, is implicated in the development and progression of hypertension. This study was preformed to identify whether serum GGT level is associated with progression of hypertension among community-dwelling population in Korea. The study subjects were participants enrolled in Hallym Aging Study, population based cohort aged 45 or over constructed in 2004. Follow-up survey was conducted in 2007. They were invited to a general hospital and were measured for clinical tests. Structured questionnaire was used to collect information on socio-demographic factors, past medical history, and behavioral factors by trained interviewers. We analyzed whether GGT level at baseline have an effect on progression of hypertension in follow-up survey using multivariate logistic regression analysis. Out of 647 men and women participated in both baseline and follow up study, 230 subjects without hypertension based JNC-7 criteria at baseline survey were enrolled in the final analysis. Among 230 subjects without hypertension at baseline survey, 115 subjects (50%) were found to develop new hypertension at the follow-up survey. 3 year cumulative incidence of hypertension according to GGT level classified by quartile were 35.6, 52.6, 54.7, and 57.1%. After adjusting for potential covariates, the adjusted odds ratio [aOR] comparing Q3 and Q4 to Q1 of baseline GGT for the risk of progression of hypertension were 2.59(95% Confidence Interval [CI]=1.10-6.73) and 3.19(95% CI=1.14-8.93), respectively. These results suggest that higher serum GGT level was an independent risk factor of hypertension progression among community dwelling adults in Korea.

## THE EFFECT OF INFLAMMATION ON BONE TURNOVER MARKERS AND BONE MINERAL DENSITY IN MEN AND WOMEN FOLLOWING HIP FRACTURE

J. Chan, D. Orwig, R.R. Miller, M. Shardell, E. Streeten, M. Hochberg, J. Magaziner, *University of Maryland Baltimore, Baltimore, Maryland*

Inflammatory cytokines are known to affect the normal bone remodeling process. Following hip fracture, inflammation is a physiological response to both the event and its surgical repair, and inflammatory cytokine levels may remain elevated for a year. This analysis examined how inflammatory cytokines are related to bone turnover markers (BTM) and bone mineral density (BMD) in the six months following hip fracture, and explored how the relationship differs between males and females. Serum was analyzed for the inflammatory cytokines sTNF-αR1 and IL-6, and the BTMs, PINP, a marker of formation, and CTX, a marker of resorption. BMD was measured by DXA. DXA were performed and serum collected at baseline (within 15 days of hospital admission) and 2- and 6-months after fracture. Generalized estimating equations modeled the association of inflammatory cytokine levels with BMD and BTM over time adjusting for covariates. The analyses included 151 participants (75 men, 76 women). In men, higher levels of IL-6 and lower levels of sTNF-αR1 were associated with lower femoral neck (p=.0048, p=.0033, respectively) and total hip BMD (IL-6: p=.0129, sTNF-αR1: p<.07). Patterns in the relationship between inflammatory cytokines and BMD differed in women, however: IL-6 levels were positively associated with BMD (p>.09), while sTNF-αR1 levels were inversely associated with BMD. Across all participants, sTNF-αR1 levels were positively, but non-significantly, associated with CTX (p>.07). Additional support for a relationship with inflammation and BTM was non-evident. These results demonstrate that inflammation may affect BMD following hip fracture and this relationship may vary between men and women.

## ENDOGENOUS SECRETORY RECEPTOR FOR ADVANCED GLYCATION END PRODUCTS AND CHRONIC KIDNEY DISEASE

M.S. Dalal[1], R. Semba[1], K. Sun[1], S. Bandinelli[4], R. Varadhan[1], J. Walston[1], J. Guralnik[2], L. Ferrucci[3], *1. Johns Hopkins Medical Institutions, Baltimore, Maryland, 2. Laboratory of Epidemiology, Demography, and Biometry, NIA, NIH, Bethesda, Maryland, 3. Longitudinal Studies Section, Clinical Research Branch, NIA, NIH, Baltimore, Maryland, 4. Azienda Sanitaria Firenze, Florence, Italy*

Advanced glycation end products (AGEs) and the receptor for AGEs (RAGE) have been increasingly implicated in pathological processes related to aging. The relationship of endogenous secretory receptor for AGEs (esRAGE) and chronic kidney disease (CKD) has not been well-characterized. The aim of the study was to determine whether plasma esRAGE is associated with chronic kidney disease (CKD) and is predictive of developing CKD in older adults. The relationship between plasma esRAGE and CKD (>stage 3 of National Kidney Foundation classification; estimated glomerular filtration rate [eGFR] <60 ml/min/1.73 m2) and CKD at 6 years follow-up was examined in a cross-sectional and prospective study design in 1020 men and women, ≥65 years, in the InCHIANTI study, a population-based cohort study of aging in Tuscany, Italy. Plasma esRAGE was measured using ELISA (B-Bridge International, Mountain View, CA). At enrollment, 158 (15.5%) had CKD. Mean (Standard Deviation [S.D.]) plasma esRAGE was 0.45 (0.24) ng/mL. Plasma esRAGE (ng/mL) was associated with CKD (Beta = 1.28, Standard Error = 0.12, P <0.007) in a multivariable linear regression model, adjusting for potential confounders. Plasma esRAGE was an independent predictor of incident CKD over 6 years of follow-up (Hazards Ratio per 1 S.D. = 1.42, 95% Confidence Interval 1.13, 1.78; P <0.003) in a multivariable Cox proportional hazards model, adjusting for potential confounders. Elevated plasma esRAGE is associated with CKD and is an independent predictor of incident CKD in older community-dwelling adults.

## RELATIONSHIP OF INFLAMMATION AND ANTIOXIDANTS WITH ENDOGENOUS SECRETORY RECEPTOR FOR ADVANCED GLYCATION END PRODUCTS IN OLDER COMMUNITY-DWELLING ADULTS

C. Crasto[1], R. Semba[1], K. Sun[1], M.S. Dalal[1], S. Bandinelli[2], J. Guralnik[3], L. Ferrucci[4], *1. Johns Hopkins, Baltimore, Maryland, 2. Azienda Sanitaria Firenze, Florence, Italy, 3. Laboratory of Epidemiology, Demography, and Biometry, NIA, NIH, Bethesda, Maryland, 4. Longitudinal Studies Section, Clinical Research Branch, NIA, NIH, Baltimore, Maryland*

Advanced glycation end products (AGEs) and the receptor for AGEs (RAGE) have been increasingly implicated in pathological processes related to aging. The role of endogenous secretory receptor for AGEs (esRAGE) in aging is not well understood. Elevated circulating esRAGE is thought to act as a decoy by binding circulating AGEs and preventing activation of the AGE-RAGE pathway, but whether high or low esRAGE is beneficial to health is not known. The objective of this study was to characterize the cross-sectional relationships between elevated levels of esRAGE and biomarkers for inflammation, cardiovascular risk, and circulating antioxidants in 1020 adults, ≥65 years, in the InCHIANTI study, a population-based cohort study of aging in Tuscany, Italy. Plasma esRAGE was measured using ELISA (B-Bridge International, Mountain View, CA). Mean (Standard Deviation) plasma esRAGE was 0.45 (0.23) ng/mL. Plasma esRAGE was not significantly associated with triglycerides, cholesterol, plasma carotenoids, vitamin E, or plasma polyunsaturated fatty acids. Serum interleukin-6 (beta = 0.025, standard error [SE] = 0.008, P = 0.002), C-reactive protein (beta = -0.009, SE = 0.003, P = 0.0006), and selenium (beta = -0.003, SE = 0.001, P = 0.02) were associated with plasma esRAGE in a multivariate linear regression model, adjusting for age, sex, body mass index, renal function, and other potential confounders. Elevated plasma esRAGE was associated with inflammation and a marker of elevated oxidative stress in older community-dwelling adults.

## EFFECTS OF POWER VERSUS RESISTANCE TRAINING IN PREFRAIL COMMUNITY DWELLING OLDER PERSONS

M. Drey[1], J. Bauer[1], A. Zech[2], K. Pfeifer[2], E. Freiberger[2], W. Uter[2], C. Sieber[1,2], *1. Klinikum Nürnberg, Nürnberg, Germany, 2. University of Erlangen-Nürnberg, Erlangen, Germany*

Introduction: As a consequence of deteriorating functional status, prefrail and frail older persons are at high risk for negative health outcomes. The objective of the present study was to compare the effects of power versus resistance training on the functional status in prefrail older persons. Methods: 69 community dwelling prefrail older persons >65 years, according to the Fried frailty definition, were included in the study. Equal numbers of participants were randomized into a resistance training group, a power training group and a control group. Training sessions were held twice per week for 60 minutes over 12 weeks. Controls received two lectures about a healthy life style. Primary outcome was the global score of the Short Physical Performance Battery (SPPB). Secondary outcome was the appendicular lean mass (aLM), measured by Dual Energy X-ray Absorptiometry (DEXA). Results: Regarding changes of the SPPB score from baseline, significant heterogeneity was observed (p=0.028). In pairwise comparisons, participants in both training groups increased their SPPB score (Δmedian=1) compared to controls significantly (p=0.011 for both). No statistically differences were found in changes in aLM between the groups (p=0.736), although there was an increase in aLM in both training groups compared to controls, whose aLM decreased. Drop out rate in the power training group (25%) was higher than in the resistance training group (13%). Conclusion: Both training modes improve functional status in prefrail older persons. With regard to drop out rates, resistance training appears to be advantageous when compared to power training.

### DETECTABLE CYTOMEGALOVIRUS (CMV) DNA PREDICTS HIGH CMV-SPECIFIC CD8+ T-CELLS IN HLA-A2+ OLDER ADULTS

X. Yao[1], S.X. Leng[1], R. Semba[1], J. Bream[2], J. Margolik[2], *1. Johns Hopkins University, Baltimore, Maryland, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland*

Recent studies have shown CMV-specific CD8+ T-cell clonal expansion and shrinking T-cell repertoire in CMV-seropositive older persons, suggesting chronic CMV infection as a driving force in T-cell immunosenescence. However, significant controversy exists regarding the relationship between CMV serology and CMV-specific T-cell expansion in older adults. To seek physical evidence of CMV infection beyond serology in this population, we assessed CMV viral DNA in monocyte-enriched peripheral blood mononuclear cells by nested PCR in 16 HLA-A2 positive elderly volunteers (mean age=83 years, range 72-90) who had positive CMV serology. Only nine (56%) had detectable CMV DNA. Moreover, these individuals had significantly higher percentages of CMV pp65-specific CD8+ T-cells by Class I tetramer analysis than those without detectable CMV DNA (mean+SD: 5%+7% vs 0.09%+0.05%, respectively, p<.001 by Kruskal-Wallis test). These results challenge the current diagnostic paradigm and provide novel insight into chronic CMV infection and its immunological consequences in the elderly.

### HIV PATHOGENESIS EMULATES IMMUNOSENESCENCE IN GUT ASSOCIATED LYMPHOID TISSUE

S. Sankaran-Walters[1], L. Nagy[1], M. Macal[1], M. George[1], T. Prindiville[1], M. Miller[1], J. Flamm[2], S. Dandekar[1], *1. University of CA, Davis, Guinda, California, 2. Kaiser Permanente, Sacramento, California*

Background About 15.4 million women are living with Human Immunodeficiency Virus (HIV) infection worldwide. HIV infection results in the loss of CD4+ T cells in the peripheral blood and Gut Associated Lymphoid Tissue (GALT). HIV disease progression correlates with immune activation. A growing proportion of HIV-infected women are now over 50 years old. With chronic inflammation, as seen in HIV infection, the pathogenic effects of HIV in GALT may be exacerbated during the course of aging and menopause. Methods We evaluated peripheral blood and GALT lymphocyte subsets in controls and HIV-positive participants using flow cytometry. Gene expression profiles in GALT were analyzed using microarray technology, real-time PCR and Robust Multi-Chip based statistical criteria. Results HIV-negative postmenopausal women demonstrated higher percentages of activated T cells in blood and GALT compared to premenopausal women. We observed an increase in gene expression associated with inflammation and T cell activation in CD4+ T cells in healthy postmenopausal controls. Gene expression associated with immune activation and antigen presentation was increased in dendritic cells in healthy postmenopausal women compared to premenopausal women similar to that observed in HIV-positive patients of all age groups. Conclusions HIV-induced T cell activation occurs in GALT early in infection, contributes to cellular immune exhaustion and emulates immunosenescence in gut mucosa. This may result in the delayed repopulation of CD4+ T cells in GALT following antiretroviral therapy. These studies provide the foundation for further investigation of the effects of gender, menopause and aging on HIV pathogenesis.

### LOSS OF SYNAPTIC INTEGRITY IN AGED APOE4 MICE

P.M. Sullivan[1,2], B. Mace[1,2], R. Klein[1,2], S. Moore[1,2], *1. medicine, Duke university, Durham, North Carolina, 2. Durham VA medical center, Durha,, North Carolina*

Individuals who carry an APOE4 allele are at greater risk for age related cognitive decline and Alzheimer's disease compared to APOE2 and E3 carriers. Over one quarter of the US population carry an APOE4 allele. We intend to test the idea that brain apoE protein levels determine relative risk of cognitive decline. We use a human apoE targeted replacement (TR) mouse model to study the relationship between apoE protein levels, age and cognitive decline. We have data which shows significant changes in apoE protein levels and synaptic transmission in human apoE4 TR mice. We also intend to show a correlation between low apoE4 protein levels and reductions in essential fatty acids required for synaptic plasticity. Preliminary studies in our lab show that exposing the TR mice to a Westernized diet exacerbates the cognitive decline in apoE4 TR mice. Our long term goal is to determine if Westernized diets worsen the risk of cognitive decline in apoE4 mice, and if so, how.

### REGULATION OF CARDIAC MICRORNAS BY SERUM RESPONSE FACTOR

X. Zhang[1], G. Azhar[1], S.A. Helms[1], J.Y. Wei[1,2], *1. Geriatrics, University of Arkansas for Med Sciences, Little Rock, Arkansas, 2. GRECC, GRE, CAVHS, Little Rock, Arkansas*

Objective: MicroRNAs are recently discovered regulators of gene expression and are recognized as important regulators of cardiac structure and function. Since serum response factor (SRF) is a transcription factor that regulates many immediate-early genes and cardiac muscle genes through serum response element, we hypothesized that SRF might also regulate certain microRNAs that are important to cardiac function. Methods: We utilized Exiqon microarray to analyze the microRNA expression in wild-type mice and a transgenic cardiac-specific mouse model in which the young adult heart resembles that of the typically aged heart. Results: We observed 50 cardiac-enriched microRNAs in the wild-type mouse heart, which accounted for 80% of the total microRNA expression. 20 microRNAs were significantly impacted by SRF overexpression, 18 of which are novel SRF target microRNAs. MicroRNA detection at 7 days, 2, 4 and 6 months of ages revealed that dysregulation of mir-1, mir-133a and mir-21 occurred 7 days after birth in the transgenic mouse heart, long before the onset of cardiac hypertrophy, indicating that SRF regulated microRNAs may contribute to cardiac hypertrophy. Bioinformatic analysis revealed that miR-199a, miR-199b, mir-214, miR-455, mir-497 and mir-499 could inhibit SIRT1, SIRT4 or FOXO family proteins. Importantly, we observed that SRF regulates microRNA biogenesis through transcriptional regulation where it controls the amount of pri-microRNA available for downstream microRNA maturation process. Conclusions: Age-related increase of SRF protein in the rodent heart during typical adult aging may contribute to altered expression of many cardiac genes and microRNA genes and affect cardiac structure and performance in senescence.

### LOSS OF TABLE MANNERS IN AGED MICE LEADS TO FOOD CONSUMPTION PARADOX

M.E. Starr[1,2], H. Saito[1,2], *1. Department of Surgery, University of Kentucky, Lexington, Kentucky, 2. University of Texas Medical Branch, Galveston, Texas*

Dietary restriction is a well-known method for extending lifespan and reducing the incidence of age-associated pathologies in laboratory rodents. One of the most commonly used protocols for dietary restriction involves monitoring the daily food consumption (food disappearance from receptacle) of freely fed animals and feeding a percentage (usually 60-70%) of that to the dietary restricted animals. Though dietary restriction is often started at an early age and continued throughout life, recent studies have shown improved health using short-term models of dietary restriction started later in life. In this study we evaluated the food consumption of adolescent (2 months-old), adult (5 months-old), old (20 months-old) and very old (29 months-old) C57BL/6 mice. To effectively evaluate actual food consumption, mice were housed on wire-bottom cages and the amount of food disappearing from the food receptacle as well as the amount of food dropped to the cage bottom was monitored. We found that a significant portion (20-40%) of food was dropped to the cage bottom daily and this phenomenon lead to an overestimation of actual food consumption, particularly in old and very old mice. When housed on bedding, dropped food was still not consumed. Additionally, we found that although total food consumption increased in old age, food intake per gram of body weight declined significantly with age. Differences in actual vs. apparent food consumption were also observed in repeated experiments with adult and old Balb/c mice. These findings point out that caution should be taken to accurately quantify food consumption by aged mice.

### SIRTUIN ACTIVATING COMPOUNDS INHIBIT REACTIVE OXYGEN SPECIES AND OSTEOCLASTOGENESIS

M. Pang[1,2], M. Rodríguez-Gonzalez[1,2], M. Hernandez[1,2], I. Fernandez[1,2], B.R. Troen[1,2], *1. Miami VAHS Geriatric Research Education and Clinical Center, Miami, Florida, 2. University of Miami Miller School of Medicine, Miami, Florida*

Osteoporosis is a widely prevalent contributor to frailty and results from an imbalance between bone resorption and bone formation leading to progressive bone loss, fractures, and increased morbidity and mortality. Reactive oxygen species (ROS) play a critical role in the formation and function of osteoclasts and therefore bone resorption. Sirtuin activating compounds (STACs) such as resveratrol (RSV) are prolongevity agents that can extend healthspan in vertebrates. Resveratrol enhances bone mineral density in mice, and sirtuin knockout mice exhibit increased osteoclastogenesis. Sirt1 expression decreases with ovariectomy and is increased by estrogen treatment in vivo. We propose that treatment with STACs will restore the youthful balance between osteoclastic bone resorption and osteoblastic bone formation and maintain bone quality, and are therefore investigating the impact of novel sirtuin1 (Sirt1) specific activating compounds (SRT2183 and SRT1720) on bone during aging.<p> We have been studying RAW264.7 cells and bone marrow cells, both of which can be induced to form functioning multinucleated osteoclasts. We have found that SRT2183 and SRT1720 inhibit osteoclast formation in a dose-dependent manner in both RAW264.7 cells and bone marrow cells, whereas RSV does not. SRT2183 also inhibits resorption of dentine by osteoclasts. SRT2183 enhances mitochondrial function in osteoclast precursors and also enhances viability and reduces the generation of ROS in response to oxidative stress. Furthermore, SRT2183 inhibits the stimulation of ROS by RANKL during osteoclastogenesis, whereas RSV does not. However, RSV treatment in vivo of young mice decreases osteoclastogenesis and increases osteoblastogenesis. MicroCT analysis reveals that the RSV treatment markedly increased bone volume. Moreover, RSV increases mineralization by osteoblasts in vitro. We have also found that osteoclast formation is increased in bone marrow cells from older mice, whereas Sirt1 expression is reduced.<p> Therefore STACs may disrupt osteoclastogenesis and osteoclast function by interfering with the generation of ROS. STACs also enhance osteoblastogenesis. Interestingly, RSV is not effective in vitro, but appears to exert potent effects in vivo. Consequently, STACs appear to exert novel anti-resorptive and anabolic effects upon the skeleton and offer significant potential as therapeutic agents to regulate the balance between osteoclastic bone resorption and osteoblastic bone formation to enhance bone mineral density and bone quality.

### RETINAL MICROVASCULAR ABNORMALITIES AND FUNCTIONAL LOSS IN OLDER PERSONS - THE CARDIOVASCULAR HEALTH STUDY

D. Kim[1,3], I. Hajjar[1,2], E. Newton[2], A.B. Newman[4], E.S. Strotmeyer[4], R. Klein[5], M. Sarnak[6], L. Lipsitz[1,2], *1. Gerontology, Beth Israel Deaconess Medical Center, Boston, Massachusetts, 2. Hebrew SeniorLife, Boston, Massachusetts, 3. Harvard School of Public Health, Boston, Massachusetts, 4. University of Pittsburgh, Pittsburgh, Pennsylvania, 5. University of Wisconsin, Madison, Wisconsin, 6. Tufts Medical Center, Boston, Massachusetts*

Background: It is unclear whether retinal signs, reflecting microvascular disease, are associated with executive dysfunction, slow gait, and depressed mood, which are characteristic features of dysfunction in frontal subcortical regions. Methods: In the Cardiovascular Health Study, 1744 participants (mean age 78) were alive free of stroke and had available retinal photographs and carotid intima-media thickness during the 1997-1998 examination. We used linear and logistic regression to examine the cross-sectional association of retinal signs with digit-symbol substitution test (DSST) score, gait speed, and depressed mood, defined as the Center for Epidemiologic Studies – Depression scale > 9. Results: Each retinal sign was associated with different vascular risk factors: generalized arteriolar narrowing, retinopathy, and focal arteriolar narrowing (hypertension); retinopathy (diabetes); and generalized venular dilation (current smoking). After adjusting for vascular risk factors and carotid intima-media thickness, generalized arteriolar narrowing (-1.21 points [95% confidence interval: -2.25, -0.17]; P = 0.022) and arteriovenous nicking (-2.00 points [-3.83, -0.18]; P = 0.031) were associated with lower DSST score. Generalized arteriolar narrowing (-0.016 m/sec [-0.031, -0.002]; P = 0.030) and retinopathy (-0.049 m/sec [-0.077, -0.022]; P < 0.001) were associated with slower gait. Generalized venular dilation was inversely associated with depressed mood (odds ratio, 0.71 [0.51, 0.98]; P = 0.035). There was a significant effect modification by carotid intima-media thickness of arteriovenous nicking on DSST score and of generalized venular dilation on gait speed. Conclusion: Our findings suggest the independent and potentially synergistic effect of microvascular and macrovascular disease in development of executive dysfunction and slow gait.

## SESSION 795 (SYMPOSIUM)

### TARGETING SIGNALING PATHWAYS IN CANCER, NEURODEGENERATION AND LONGEVITY

Chair: *G.J. Lithgow, Buck Institute for Age Research, Novato, California*

A number of intracellular signaling pathways determine the lifespan of simple animals. The Discovery that TOR signaling determined lifespan in invertebrates generated considerable interest in this pathway that was already known to have links to cancer. A chemical inhibitor of this pathway, a known drug, extends lifespan in lab mice. The scene is now set for the development of interventions in aging and age-related disease based on our understanding of this pathway. Speakers: Pankaj Kapahi, The Buck Institute Matt Kaeberlin University of Washington, Seattle Randy Strong, Barshop Institute Veronica Galvan, University of Texas Health Science Center at San Antonio

# SESSION 800 (SYMPOSIUM)

### AGING AND WORK: ISSUES AND IMPLICATIONS IN A CHANGIN LANDSCAPE

Chair: *S. Czaja, Psychiatry and behavioral sciences, university of miami miller school of medicine, Miami, Florida*
Discussant: *D. Ekerdt, University of Kansas, Kansas, Kansas*

The twenty-first century workplace will be shaped by numerous factors resulting in many challenges for employers and workers that require changes in policies, work procedures, and training systems. Current and projected demographic and economic trends create a need for organizations to accommodate an increasingly older diverse older workforce. At the same time, changes in work structures and ongoing developments in technology create a need for workers to accommodate changes in job demands. This symposium will highlight key issues confronting the future of work in an aging population. S. Czaja will present an overview of the landscape of the workplace of the 21st century and discuss some of the challenges confronting older workers and organizations. R. Schulz will discuss work and caregiving and present some current data from a recent study of working caregivers and employer healthcare costs. N. Charness will provide a discussion of aging, skill acquisition and present some data regarding strategies to enhance training of older workers. J. Sharit will focus on the challenges and opportunities afforded by telework for older workers and highlight some findings from a survey of managers regarding older teleworkers. Finally, R. Wallace, will address the topic of worker wellness and health promotion programs. The goals of the symposium is to provide an overview of emerging research related to aging and work and to highlight critical and timely issues that need to be addressed to accommodate an aging workforce. D. Ekerdt will lead a discussion of these topics and highlight some future research needs.

### WELLNESS PROGRAMS FOR OLDER WORKERS: DO THEY REALLY EXIST?

R.B. Wallace, *The University of Iowa, Iowa City, Iowa*

This presentation will address the availability and scope of Employee Assistance Programs (EAPs) specifically designed for the older worker. In fact, relatively few such programs exist, despite the fact that older workers may participate in EAPs that are suitable for all ages. Reasons for this lack of availability are varied, but ultimately are not easy to determine. This presentation will suggest which programs are likely to be successful at the worksite and some of the impediments to the establishment and maintenance of such programs.

### THE EMPLOYABILITY OF OLDER WORKERS AS TELEWORKERS

J. Sharit[1], S. Czaja[2], M.A. Hernandez[2], S.N. Nair[2], *1. University of Miami, Coral Gables, Florida, 2. University of Miami Miller School of Medicine, Miami, Florida*

Telework has the potential to accommodate many of the needs and preferences of older workers. The viability of telework as a work option for many older workers, however, requires the consideration of issues such as the ability of older workers to adapt to the technological demands that are often associated with telework jobs and managerial attitudes toward older teleworkers. We present findings from a questionnaire study that assessed managers' perceptions of worker attributes desirable for telework and how managers felt older workers compared to younger workers on these attributes. The sample included 314 managers with varying degrees of managerial experience from a large variety of companies in the U.S. The results presented a mixed picture with respect to the employability of older workers as teleworkers, and strongly suggested that less experienced managers would be more resistant to hiring older people as teleworkers.

### AGE AND SKILL ACQUISITION: A FRAMEWORK FOR GUIDING OLDER WORKER TRAINING

N. Charness, *Psychology, Florida State University, Tallahassee, Florida*

The goal for this presentation is to provide a framework for understanding the enabling conditions for skill acquisition in older adulthood. I'll review some of the motivational determinants for self-improvement highlighting age-related changes in motivation. Then I'll examine some classic age-performance functions developed to describe high-level human performance, highlighting some recent data that suggest a shift from the 30s to the 40s for peak performance. Next I'll review some individual difference factors, mainly cognitive abilities that mediate skill acquisition processes. I'll then describe some example studies of skill acquisition in both work-like and work environments. Drawing on the results of those studies and an economic analysis of age and productivity, I'll provide some recommendations for how to support skill acquisition (and maintenance) by older workers.

### COMBINING CAREGIVING AND WORK: PREVALENCE, HEALTH EFFECTS, AND POLICY

R. Schulz, S. Albert, *University of Pittsburgh, Pittsburgh, Pennsylvania*

Of the more than 43 million adults providing care to someone age 50 or older, 50% have full time jobs and 11% have part time jobs. Combining work and caregiving can be a challenge. Two-thirds of working caregivers make workplace accomations including going in late, leaving early or taking time off during the day to provide care. Data also indicate that working caregivers have more chronic health conditions and incur higher health care costs for employers. These findings raise the question, what strategies might maximize worker preformance and minimize caregiving distress? We conclude with a discussion of caregiver work policies that have been implemented, their effectivness, and ways in which they might be improved.

# SESSION 805 (SYMPOSIUM)

### CARING, SHARING AND WELL-BEING: DATA FROM AUSTRALIAN AND NEW ZEALAND LONGITUDINAL STUDIES

Chair: *N.A. Pachana, Psychology, University of Queensland, Brisbane, Queensland, Australia*
Discussant: *F.M. Alpass, Massey University, Palmerston North, New Zealand*

Longitudinal studies of aging processes provide unique perspectives on a range of health, emotional and social processes over time. Globally, increases in the proportion of older adults within the population make the data gleaned from longitudinal studies of increasing importance. Social behavioural phenomena, particularly as they interact with health outcomes and well-being over time, are of particular interest. Data in this symposium come from four large longitudinal studies located in Australia and New Zealand: the Australian Longitudinal Study on Women's Health (ALSWH); the New Zealand Longitudinal Study of Ageing (LSA); the Australian Men, Women and Ageing (MWA); and the New Zealand Enhancing Wellbeing in an Ageing Society (EWAS) studies. Topics covered in this symposium include the following: quantitative and qualitative data used to examine factors which may inhibit or enhance social support in older women (ALSWH); an examination of the interrelationships between caregiving, gender and ethnicity on the physical and mental health of older New Zealanders; a comparative study of sexual activity in Australian men and women aged 82 to 87 years; and associations between subjective wellbeing and Amartya Sen's capability variables including participation in leisure and recreational activities, access to shops and public transport, homeownership, income, employment, participation in community organisations and health. This symposium offers a wide range of important data on social, emotional and role functioning with respect to physical and mental well-being in later life.

### AGEING, WELLBEING AND CAPABILITY

C. Waldegrave[1], P. King[2], *1. Family Centre Social Policy Research Unit, Wellington, New Zealand, 2. Family Centre Social Policy Research Unit, Wellington, New Zealand*

The aim of this research was to identify the drivers of wellbeing and quality of life among the older population. Amartya Sen's capabilities approach has formed the conceptual basis of the theoretical framework (Sen, 1999). This paper will report on the results of a study of ageing and wellbeing with a national random sample of 1,680 New Zealanders aged 65 to 84 years using computer assisted technology interviewing (CATI). Information was sought from survey respondents on their participation and achievement in a range of capability areas and this was set alongside the subjective measures of satisfaction to provide a broad view of how capability and satisfaction contribute to wellbeing. The results demonstrated significant associations between subjective wellbeing and capability variables that included participation in leisure and recreational activities, access to shops and public transport, homeownership, income, employment, participation in community organisations and health.

### GENDER, ETHNICITY AND THE IMPACT OF CAREGIVING ON THE HEALTH OF OLDER NEW ZEALANDERS

F. Alpass, C. Stephens, R. Pond, A. Towers, *Psychology, Massey University, Palmerston North, New Zealand*

An ageing population will lead to an increase in the prevalence of chronic diseases, including dementia. The provision of informal care by family will also increase. Caregivers are more likely to be older women, who report greater caregiver burden than male caregivers. Cultural differences also influence caregiver outcomes. We examined the interrelationships between caregiving, gender and ethnicity on the health of older New Zealanders. Participants (N=2,484) from the first two waves of the New Zealand Longitudinal Study of Ageing completed surveys. Hours of care, gender and ethnicity were not directly related to declines in health or function from 2006 to 2008, however Māori (indigenous New Zealanders) with high levels of caregiving were more likely to suffer a health decline than non-Māori. Hours of care, gender and ethnicity were unrelated to physical health scores in 2008 but Māori had lower mental health scores, with those providing high levels of care having the lowest scores. The multiple roles of elder Māori are thought to contribute to these outcomes.

### NORMAL SEXUAL FUNCTIONING IN OLDER PEOPLE

D. McLaughlin[1], K.A. McCaul[2], L. Flicker[2], Z. Hyde[2], O. Almeida[2], G. Hankey[2], K. Jamrozik[3], J. Byles[4], *1. School of Population Health, The University of Queensland, Herston, Brisbane, Queensland, Australia, 2. The University of Western Australia, Perth, Western Australia, Australia, 3. The University of Adelaide, Adelaide, South Australia, Australia, 4. The University of Newcastle, Newcastle, New South Wales, Australia*

Older people continue to engage in sexual activity into advanced years. We performed a comparative study of sexual activity in men and women aged 82 to 87 years resident in Perth, Australia. Men who participated in the Health in Men Study were surveyed about sexual activity. Women from the older cohort of the Australian Longitudinal Study of Women's Health who were resident in Perth were asked to complete an additional questionnaire about sexual activity. Men were more likely to report sexual activity within the last 12 months and less likely to rate sex as not at all important. Women were more likely to report the absence of a partner. For both sexes the lack of an interested partner was a frequent reason given for the lack of sexual activity. In late adulthood, gender differences in the amount and perceived importance of sexual activity exists between older men and women.

### FACTORS WHICH ENHANCE OR INHIBIT SOCIAL SUPPORT: A LONGITUDINAL ANALYSIS OF SOCIAL NETWORKS IN OLDER WOMEN

N.A. Pachana, D. McLaughlin, J. Adams, A. Dobson, *School of Population Health, The University of Queensland, Herston, Brisbane, Queensland, Australia*

Older people with strong social support have lower mortality and morbidity and better self-rated health in later life. Few studies have used longitudinal data to examine factors which may inhibit or enhance social support. This study used both quantitative and qualitative data to explore older women's social networks. Participants were drawn from participants in the Australian Longitudinal Study on Women's Health (ALSWH) who were born in 1921-26. Larger social networks were associated with better mental health, being widowed, illness or death of a family member and no mobility problems. Women who were not Australian born, had sight problems or who had recently moved house were more likely to have smaller social networks. The use of a mixed methodology enabled the longitudinal quantitative results to be enriched by the women's own views. This research highlights the importance to older women of being able to psychologically, emotionally or physically access their social networks.

## SESSION 810 (SYMPOSIUM)

### CURRENT RESEARCH ON GRANDPARENTS RAISING GRANDCHILDREN: CUTTING EDGE METHODOLOGIES

Chair: *L. Yancura, University of Hawaii, Honolulu, Hawaii*
Discussant: *B. Hayslip, University of North Texas, Denton, Texas*

The number of grandparents raising grandchildren (GRG) has increased dramatically over the past few decades. The number and scope of studies of GRG in the academic literature has grown as well. Corresponding to this growth, research on GRG has become increasingly sophisticated in its use of methodological approaches to understand how contextual factors influence the health and well-being of GRG. Many of these approaches are being used in response to specific characteristics of the GRG population, which are similar to other populations used in gerontological research. The GRG population is difficult to locate and recruit, contains a high percentage of ethnic minorities and includes GRG from a range of social and economic situations. The well-being of GRG is also closely associated with family-level characteristics. Presenters in this symposium address a range of methodologies currently being used to study GRG. These methodologies include strategies for recruitment of culturally diverse samples, techniques for retaining participants in probability samples of longitudinal studies, qualitative methods such as classical grounded theory, and practical approaches for gathering family-level data in grandparent-headed families. Those who attend this symposium will be able to identify current trends in research on GRG and discuss cutting edge research methodologies being used to study these trends.

### OPPORTUNITIES AND CHALLENGES IN MULTIGENERATIONAL RESEARCH WITH GRANDPARENT-HEADED FAMILIES

M.L. Dolbin-MacNab, *Human Development, Virginia Polytechnic Institute and State University, Blacksburg, Virginia*

Despite increased interest in grandchild adjustment and family processes within grandparent-headed families, most researchers continue to gather data from only one family member, typically the grandparent. While grandparent data are valuable, there is much that can be learned about grandparent-headed families by obtaining data from multiple family members such as spouses or partners, grandchildren, and the middle generation. The purpose of this presentation is to provide researchers with practical guidelines for designing and executing multigenerational research with grandparent-headed families. Using lessons learned from studies of custodial grandmothers and their adolescent grandchildren, the presentation will address effective recruitment and retention strategies, as well as issues associated with securing informed consent. Emphasis will also be given to recommendations related to measurement, data management, and appropriate data analysis. Finally, given that multigenerational research in grandparent-headed families may result in ethical challenges, specific attention will be given to strategies for addressing these ethical concerns.

### CLASSICAL GROUNDED THEORY: EXPLORING CUSTODIAL GRANDPARENT-GRANDCHILD RELATIONSHIPS

C.J. Tompkins, *George Mason University, Fairfax, Virginia*

There are 2.4 million grandparents in this country who have the primary responsibility of raising their grandchildren (U.S. Census, 2000), often under challenging circumstances. This study used classical (Glaserian) grounded theory to explore the relationships between grandparents and grandchildren residing within a grandparent-headed household. Grounded theory is a rigorous, inductive research methodology that uses constant comparative analysis to generate explanatory theory directly from data. For over two years, this researcher worked with a classical grounded theorist in order to learn and realize the rigor of the methodology. Twelve grandmothers, 1 grandfather and nine grandchildren were interviewed. These interviews as well as interviews from caregivers of older adults and the caregiving and grandparenting literature were all used as data. This presentation will focus on the collaboration with a grounded theorist and the use of this methodology in generating the core variable explaining caregiving relationships: CPR Partnering – Caring, Protecting and Responding.

### WALKING THE RED ROAD: FIRST NATIONS' GRANDPARENT CAREGIVERS PROMOTING RESILIENCY AND CULTURAL HEALTH

E. Fuller-Thomson, G.E. Thompson, R.E. Cameron, *Faculty of Social Work, University of Toronto, Toronto, Ontario, Canada*

Like American Indian and Alaskan Natives, First Nations Canadians are vastly over-represented among grandparent caregivers. The purpose of this grounded theory study was to provide a framework for understanding the contemporary experience of First Nations grandparent caregivers (n=15). Recruitment of this difficult to locate population was extremely challenging. Creative recruitment strategies included reliance on a bilingual interviewer (Ojibway), snowball sampling both on and off reservations, and volunteering at a Native Friendship Centre's Seniors' Lunch program to promote trust. Symbolic interactionism and social constructionism informed the analysis. Results revealed that First Nations grandparents had leveraged their own experiences of cultural disruption to reinvest in the cultural health and well-being of their grandchildren. One grandfather described this role as "walking the red road" which entailed a responsibility "to provide wisdom and . . . protection." Identified benefits of traditional grandparent care-giving included cultural healing and joy.

### ATTRITION AND RETENTION OF A GRANDMOTHER SAMPLE IN A LONGITUDINAL STUDY

C. Warner, C. Musil, N. Gordon, *FPB School of Nursing, Case Western Reserve University, Cleveland, Ohio*

This paper addresses the retention of a probability sample of 485 grandmothers (grandmothers raising grandchildren, grandmothers in multigenerational homes, and non-caregivers to grandchildren) in a longitudinal study with four waves; 351 grandmothers completed mailed questionnaires at all time points for a 72.4% retention rate. We examined factors associated with attrition, using covariates from the previous completed waves using logistic regression with forward selection. The c statistic, a measure of concordance, is 0.64. There were three statistically significant predictors of attrition: grandmother group, self-assessed health, and race. Grandmothers living in multigenerational homes compared to non-caregiver grandmothers (odds ratio 0.45 [95% CI=(0.26, 0.76)], those with worse self-assessed health (odds ratio 0.75 [95% CI=(0.61, 0.94)], and minorities (odds ratio 0.55 [95% CI=(0.36, 0.84)] were less likely to return the questionnaire. These findings provide valuable information on the characteristics of grandmother caregivers—necessary for sample maintenance in longitudinal studies. Retention strategies are discussed.

## SESSION 815 (SYMPOSIUM)

### THE USE OF MARGINS AND MISSING DATA TO EXAMINE LIMITATIONS OF THE CES-D AMONG OLDER ADULTS

Chair: *D.J. Van Dussen, Sociology, Anthropology, and Gerontology, Youngstown State University, Youngstown, Ohio*

This research examines the patterns and reasons for the patterns of missing data among a sample of 720 older residents of Continuous Care Retirement Communities using the 20 item CES-D (Radloff, 1977). Past research has not adequately examined patterns of or reasons for missing data. This presentation explores patterns of missing data quantitatively using descriptive statistics and multivariate analyses; and qualitatively using respondent comments written in the margins of the quantitative data. Reasons for missingness included ambiguity about the meaning of key words in CES-D statements and differential interpretations of statements based upon respondent's age, gender, and the context of the questions. Findings suggest that in the population studied, missing data was not random or accidental suggesting that current methods may not adequately capture the meaning of depression. The need for further mixed methods research will be discussed to improve understanding of how older adults interpret and respond to depression.

### DEPRESSION INTERVIEWS AS PERFORMATIVE: HOW THE ACT OF ANSWERING CAN CREATE SOCIAL FACTS

B. Dahlberg, *Anthropology, and Family Medicine, University of Pennsylvania, Philadelphia, Pennsylvania*

This paper draws on theory from linguistic anthropology to explore how answering questions about depressive symptoms can socially constitute someone as "a depressed person." Through discourse analysis of semi-structured interviews with older patients with depressive symptoms, I explore the stakes of taking on a label of depression, as well as the sociolinguistic processes that can construct someone as "depressed." My findings shed light on the reasons older patients may avoid answering certain questions, and emphasize that answers not only describe symptom experiences, but can also perform social facts. For example, I find that some older adults avoid "admitting" to depressed feelings because this admission would finalize a construction of them as a "depressed person." This presentation will enable participants to (1) discuss the relationships between eliciting information from patients and negotiating/constructing patients' identities, and (2) understand some of the stakes for older patients that create reasonable concerns about disclosing symptoms.

### THE CES-D AS A THINK ALOUD EXERCISE: HOW AND WHY OLDER ADULTS RESPOND TO STATEMENTS

K. de Medeiros, *1. The Copper Ridge Institute, Sykesville, Maryland, 2. The Johns Hopkins University School of Medicine, Baltimore, Maryland*

The CES-D has been used extensively in gerontological research to estimate depression prevalence in the community. Although the CES-D has been validated in older adults, few studies have explored how the elderly interpret and respond to the individual statements. The current study explored how older adults interpreted CES-D statements and what influenced their subsequent response. 42 people (21 men, 21 women) age 75 and older were enrolled. All participants completed the CES-D as a "think aloud" exercise, in which they provided detailed descriptions of each statement meant to them and their reasons for their response.

Results revealed that three statements in particular varied in meaning and response: future, friendly, and failure. Such variation could potentially lead to errors in determining depression status. Given that depression is under-reported in this population, insight into older adults' interpretation of CES-D questions is an important source of information.

## SESSION 820 (PAPER)

## EARLY LIFE, LATER OUTCOMES

### JOCKS OR BRAINS: THE LONG-TERM INFLUENCES OF HIGH SCHOOL SPORTS PARTICIPATION ON SOCIOECONOMIC SUCCESS AT RETIREMENT AGE

D. Kuo, H. Han, *University of Wisconsin, Madison, Wisconsin*

Athletics in high schools were shown with higher educational aspiration; and any studies found that being an athletic was positively associated with labor market outcomes. Yet, it is remained unclear whether the advantage of being an athletic persisted through adult life. In the current study, we explore the relationships between being an athletic in high school and life-long socioeconomic success among a large group of high school seniors in Wisconsin Longitudinal Study ("WLS") from 1957 to 2004. The high school sports participation of the respondents was coded from the yearbooks when they were 18 years old (1957). Education, occupation and income were measured at age 36, 54 and 65. The WLS was ideal for our inquires because the study contained quality information on socioeconomic background, high school grades, occupational aspiration, college plan and finance, cognitive ability at high school and in later adulthood, and a complete educational and occupational history. Our preliminary findings showed that participation in team sports was positively related to men's educational attainment at age 36, controlling for socioeconomic status, IQ, high school ranking, and occupational aspiration. In particular, being in football teams was the most strongly related to the educational attainment. In this paper, we ask the following questions, 1.Whether being an athletic in high school has an advantage on education, occupational status and income at age 36; 2.Whether the advantages remain until retirement; 3.How gender moderates the advantages.

### LIFE COURSE SOCIOECONOMIC ADVERSITY EXPERIENCE AND MULTI-SYSTEM PHYSIOLOGICAL DYSREGULATION IN LATER ADULTHOOD

T. Gruenewald, A.S. Karlamangla, C.J. Crandall, T. Seeman, *University of California, Los Angeles, Los Angeles, California*

A large body of research suggests that socioeconomic adversity experienced in both childhood and adulthood is associated with poorer physical health in adulthood, although the biological pathways underlying these connections remain to be elucidated. The current study examined whether level of multi-system physiological dysregulation varied as a function of level of socioeconomic adversity experienced in childhood and two points in adulthood. Data come from 896 (45% male, mean age = 58) participants from the Study of Midlife in the U.S. A summary childhood socioeconomic adversity score was constructed from indicators of parental education, childhood welfare status, and perceptions of a poor financial state in childhood. Summary adult socioeconomic adversity measures were constructed from indicators of own educational achievement, household income to poverty level, difficulty paying for bills and meeting basic needs, and perception of a poor current financial situation. A multi-system physiological dysregulation index was calculated by summing the number of 22 biomarkers of cardiovascular, neuroendocrine, metabolic and immune functioning for which participant values fell into high-risk quartiles. Age- and gender-adjusted dysregulation scores were higher in those with more frequent experience of high levels of socioeconomic adversity across childhood and adulthood (linear trend $p < .001$). Additional analyses indicated that health status, health behavior, and psychosocial variables accounted for 27%, 9%, and 34%, respectively, of the association between cumulative socioeconomic adversity and physiological dysregulation. These findings indicate that multiple pathways may account for greater levels of physiological dysregulation in later adulthood among those with greater cumulative experience of socioeconomic adversity.

### EARLY LIFE CONDITIONS, ADULT FRAILTY AND MORTALITY AMONG AGING POPULATIONS IN DEVELOPING COUNTRIES

M. McEniry, *CDE/CDHA, University of Wisconsin, Madison, Wisconsin*

Adverse early life conditions may have strong effects on adult chronic conditions such as obesity and heart disease which then impact adult frailty and mortality. In this paper, we compare and contrast heart disease, diabetes, obesity, frailty and mortality in older adults across a large and diverse set of countries and examine the degree to which poor early life circumstances explain the observed patterns. We include population data from major studies on aging in Latin America and the Caribbean (MHAS-Mexico, SABE-capital or major cities, PREHCO-Puerto Rico, CRELES-Costa Rica), Asia (CLHLS-China, IFLS-Indonesia, MHSS-Bangladesh, WHO/SAGE-India), Africa (WHO/SAGE-Ghana, WHO/SAGE-South Africa) and data from the US (HRS, WLS), the UK (ELSA), the Netherlands (SHARE) and Taiwan (SEBAS) to benchmark results. Frailty is defined according to mobility, range of motion and difficulty with daily activities. Using country-specific and pooled multivariate models we first estimate the effects of early life conditions (season of birth, place of birth, childhood health, SES, markers of nutritional status, mother's education) on heart disease and diabetes; then on frailty and mortality, controlling for heart disease and diabetes. We find that there is some evidence to suggest that older adults from developing countries who were exposed to adverse early life conditions are at higher odds of heart disease and diabetes as well as being at increased risk of being frail and dying. It will be important to further validate these findings and to then design effective health policies and interventions to address the health needs of older adults in these settings.

### WAR-RELATED DISABILITY AND MEN'S LATER LIFE HEALTH TRAJECTORIES

J. Wilmoth, A. London, *Syracuse University, Syracuse, New York*

The majority of older men in the United States served in the military, many during World War II, Korea, or Vietnam. Despite this, relatively little is known about how the later life health status of these men is different from men who did not serve in the military. This research uses data from twelve years of the longitudinal Health and Retirement Study (HRS) to examine three types of later life health trajectories: number of health conditions, activities of daily living (ADLs), and self-rated health. The results based on growth curve models indicate that compared to nonveterans, veterans with war-related disability have significantly higher ADLs and lower self-rated health. However they have less steep age-related increases in number of conditions and ADLs, as well as less steep age-related declines in self-rated health. In contrast, veterans without a war-related disability have significantly fewer health conditions, lower ADLs, and better self-rated health than nonveterans. They exhibit steeper age-related increases in number of conditions and greater age-related declines in self-rated health but less steep age-related increases in ADLs. These differences persist after controlling for childhood socioeconomic status, sociodemographic characteristics, and current health behaviors. Overall, the results suggest that compared to nonveterans, veterans with a war-related disability are generally in poorer health but experience fewer age-related health changes whereas veterans without a war-related disability tend to be in better health but have more age-related health changes. These findings highlight the enduring impact of military service on men's later life health outcomes.

# SESSION 825 (POSTER)

## EMOTION AND AFFECT

### NEGATIVE AFFECT, STRESSOR APPRAISAL, AND AGE DIFFERENCES IN BEDTIME CORTISOL

G.E. Ennis[1], S. Neupert[1], D. Almeida[2], *1. Psychology, NC State University, Raleigh, North Carolina, 2. Pennsylvania State University, University Park, Pennsylvania*

Higher levels of evening cortisol may be associated with alterations in glucose metabolism (Plat et al., 1999). Depressed persons and older adults have been found to have higher evening and nighttime levels of cortisol (Vreeburg et al., 2009; Yehuda, Teicher, Trestman, Levengood, & Siever, 1996). Interpreting that a stressor is a threat to one's social self can activate the hypothalamic-pituitary-adrenal axis resulting in cortisol increase (Dickerson & Kemeny, 2004). Following exposure to psychosocial stressors, cortisol tends to be higher in the recovery period in depressed compared to non-depressed individuals (Burke, Davis, Otte, & Mohr, 2005). Whether feelings of threat are related to evening cortisol have not been sufficiently investigated in either depressed persons or the general population. Utilizing data from the National Study of Daily Experiences II (a substudy of the Midlife in the United States Study), we investigated negative affect, stressor appraisal, and age differences in bedtime cortisol. Controlling for smoking, hours of sleep, number of physical symptoms, and time of cortisol collection, older adults who had higher negative affect and reported that stressors posed a greater risk to how they felt about themselves had higher bedtime cortisol than older adults who had higher negative affect and reported that stressors posed a lesser risk to how they felt about themselves. Similar stressor appraisals by younger adults were not related to differences in their bedtime cortisol levels. Results suggest that stressor appraisal may play a role in the evening cortisol levels of older adults with higher levels of negative affect.

### EMOTION RECOGNITION TRAINING IN OLDER ADULTS: WHICH INDIVIDUAL DIFFERENCE VARIABLES CONSTRAIN TRAINING EFFECTS?

M. Larcom, D. Isaacowitz, *Psychology, Brandeis University, Waltham, Massachusetts*

Some research suggests that in order to successfully recognize emotions in others, one should experience those same emotions. In the current study, we looked at individual difference factors related to emotional experience (e.g., current levels of positive and negative affect, state and trait anxiety, level of neuroticism) in older adults who either did or did not benefit from emotion recognition training. Fifty-five older adults (M = 72.20 years of age, SD = 8.67) were trained to direct their attention toward the eye or the mouth region of faces displaying angry, fearful, and sad expressions. Because both types of training affected emotion recognition accuracy to a similar extent, we examined affective predictors of the participants' greatest change in accuracy (i.e., upper limits) regardless of specific type of training. We found that older adults who improved more in their ability to recognize anger reported significantly higher levels of negative affect and trait anxiety as compared to those for whom the training was not as successful. A near significant trend was found for reports of higher neuroticism levels among those who had greater improvements for identifying sadness. For fear, however, we found a near-significant trend such that those who benefited more from training reported lower levels of negative affect. These findings indicate that affective experience may indeed constrain training effects for emotion recognition accuracy, but the nature of these effects may vary by type of emotion.

### AGE DIFFERENCES IN NEURAL CORRELATES OF AUTOMATIC AND CONTROLLED EMPATHY: AN ERP STUDY

J. Studer, N. Mella, G. Labouvie-Vief, *University of Geneva, Geneva, Switzerland*

Empathy is a complex emotion that continually develops with aging. Affective and cognitive empathy are traditionally dissociated: the affective component being concerned with resonating with another's emotional state and the cognitive component focusing on one's understanding of another's mental state as different from one's own. Recent studies have suggested that cognitive, but not affective, empathy may be impaired with normal aging. The present study explored the neural correlates of affective (automatic) and cognitive (controlled) empathy for pain from adolescence to old adulthood. 48 participants (aged from 11 to 88) watched stimuli depicting hands in painful or non painful situations and performed (1) a pain judgment task that required attention to pain cues in the stimuli (controlled empathy for pain) or (2) a counting task withdrawing their attention from these cues (automatic empathy for pain). As expected, behavioral results showed that older adults are slower and less accurate than adolescents and younger adults when attending to pain, indicating more difficulties in the controlled component. No age-related differences were found in the counting task suggesting a stability of automatic empathy between age groups. ERPs results showed an early automatic component similar across age groups and a late controlled component revealing predicted differences between adolescents, younger adults and older adults.

### UNCONSTRUCTIVE REPETITIVE THOUGHTS ARE ASSOCIATED WITH PROLONGED NEGATIVE MOOD IN YOUNGER BUT NOT OLDER ADULTS

E. Munoz[1], J. Mogle[1], J. Smyth[2], M. Sliwinski[1], *1. The Pennsylvania State University, University Park, Pennsylvania, 2. Syracuse University, Syracuse, New York*

Unconstructive repetitive thinking (URT) is associated with poor psychological and physical health (Watkins, 2008). One pathway by which URT may lead to adverse health outcomes is by amplifying and prolonging negative emotional states. The current study examines how URTs relate to negative affect and how this may differ according to age. Because older adults have difficulty inhibiting unwanted thoughts (Hasher & Zacks, 1998), we examined whether URT would be more strongly related to negative mood states in older compared to younger adults. An experience sampling study was conducted in which participants (age range 20-78 years, 53% female) reported on their negative affect and frequency of unconstructive repetitive thinking (URT) at 5 randomly determined times during the day and once in the evening on 7 consecutive days. Hierarchical mixed models indicated that the experience of URT was related to both the level and time course of negative mood. Individuals who reported experiencing URTs more often experienced higher levels of negative affect, as well as prolonged negative mood states throughout the day ($p<.05$). Contrary to expectations, this latter relationship was attenuated among older adults ($p<.05$). Negative affect was also prolonged on days when an individual experienced more URTs than usual ($p<.05$); this effect was also attenuated for older adults ($p<.05$). These results demonstrate an association between repetitive thought and the durability of negative mood, but also suggest that this association is attenuated in older compared to younger adults. Implications for developmental theories of emotion regulation are discussed.

### EMOTION REGULATION IN THE CONTEXT OF DAILY STRESS ACROSS THE ADULT LIFESPAN

H. Chui, M.K. Diehl, *Human Development and Family Studies, Colorado State University, Fort Collins, Colorado*

This research used data from a study on daily emotion experience in adulthood to examine the associations between daily stress, self-concept incoherence (Block, 1967), age, and regulation of positive and negative affect. Emotion regulation was assessed using dynamical systems modeling (Boker & Laurenceau, 2006), which described the frequency of oscillation and whether affect showed reduced amplitude of oscillation. Findings revealed that the regulation of positive affect and the regulation of negative affect were two separate systems. Changes in one affect system did not influence changes in the other. For both positive and negative affect, the frequency and damping coefficients were statistically significant. This indicated that positive and negative affect showed a systematic pattern of oscillation and the amplitude of oscillation decreased over time. When self-concept incoherence and age were added into the models, these variables did not predict the regulation of either positive or negative affect. In contrast, daily stress was a significant predictor of regulation of positive affect, such that positive affect moved back toward equilibrium more quickly than usual when individuals experienced daily stress. However, there was no evidence that daily stress influenced the regulation of negative affect. These findings support the conceptualization of positive and negative affect as two independent systems (Watson, Clark, & Tellegen, 1988). Overall, these findings contribute to the ongoing discussion on how adults regulate positive and negative affect in the context of daily stress.

## FORGET ABOUT IT: ARE THERE AGE DIFFERENCES IN THE ABILITY TO SUPPRESS MEMORY FOR EMOTIONAL EVENTS?

T. Elliott, T.M. Hess, *Department of Psychology, NCSU, Raleigh, North Carolina*

An important memory skill involves the ability to intentionally forget information that is unwanted or no longer useful. Although younger adults are relatively effective at doing so, recent research has suggested that this ability is impeded when attempting to forget negative emotional material. Given the adaptive nature of suppressing undesirable memories, it is important to determine if older adults have similar difficulties. Since older adults have specific problems with inhibitory functions, they may experience even more disruption than younger adults. Research has also suggested, however, that emotion regulation skills are maintained or even improve in later adulthood. Thus, an alternative prediction would be that older adults will experience less disruption in directed forgetting due to their increased ability to control their responses to negative information. In this study, we examined how age differences in intentional forgetting are affected by the emotional content of the to-be-forgotten materials. Using a standard directed-forgetting procedure, young and older adults (N=128) studied two pairs of word lists. The pairs of word lists were either all negative words, all neutral words, or both negative and neutral words. In contrast to younger adults, older adults exhibited directed forgetting (i.e., low recall for material they were instructed to forget) in every condition, supporting the idea that enhanced regulatory skills in later life facilitate suppression of negative memories. The importance of emotion regulation was also illustrated in the finding that directed forgetting was most efficient in those older adults who are better at down regulating their negative affect.

## WHEN ENOUGH IS ENOUGH: CHRONIC STRESSORS MAKE AGE DIFFERENCES IN AFFECTIVE REACTIVITY DISAPPEAR

G. Luong[1], S.T. Charles[1], D. Almeida[2], *1. University of California, Irvine, Irvine, California, 2. Pennsylvania State University, University Park, Pennsylvania*

Older adults often report higher levels of emotional well-being than younger adults, and researchers have attributed this finding largely to the way older adults navigate their social relationships (Blanchard-Fields, 2007). Older adults use more disengagement strategies to avoid arguments with social partners, thereby reducing affective reactivity associated with interpersonal tensions (Charles, Piazza, Luong, & Almeida, 2009). According to Strength and Vulnerability Integration (SAVI), this age-related advantage may disappear when older adults are subjected to chronic stressors for which their emotion regulation strategies are no longer effective (Charles & Piazza, 2009). The present study used data from the National Study of Daily Experiences (NSDE) to test whether older adults would continue to show less affective reactivity in response to chronic or repeated interpersonal tensions when they use disengagement strategies. Results showed that older age was only related to less affective reactivity when the avoided argument was not reported multiple times in the 8-day study period (continuation) ($\beta = -.01$, SE = .00, $p < .01$) or coded as a chronic stressor in the person's life (ongoing)($\beta = -.01$, SE = .00, $p < .05$). When interpersonal tensions were a continuation or ongoing stressor, older adults no longer reported less affective reactivity in response to the avoided argument. These findings give initial support to SAVI and point to future areas of research in aging and emotion regulation.

## AGE AND SUBJECTIVE WELL-BEING

T. Hansen, *Norwegian Social Research (NOVA), Oslo, Norway*

It is a widely held assumption, also by older persons themselves, that SWB declines with age. Indeed, this expectation seems well-founded in light of the many losses and declines (or threats thereof) that may accompany old age, in terms of roles, abilities, energy, social contacts, partner, and health (including pain and disability). However, growing old entails both gains and losses, and these changes may leave different footprints on disparate aspects of SWB. This assumption is explored using recent data from the Norwegian NorLAG study (N=10,887). Indeed, most people in the second half of life report high SWB, and age is associated simultaneously with gains and losses in SWB. Campell et al.'s (1976) conclusion that, with age, cognitive well-being improves and affective well-being deteriorates, although oversimplified, fits quite well with the NorLAG results. Whereas well-being measured with cognitive constructs such as life satisfaction and domain satisfactions increases with higher age, well-being decreases when measured by affective measures such as positive affect, depression, and loneliness. Affective age patterns in well-being are not all bad, however, since negative affect also falls with age, at least till about age 70. The most troublesome aspect of well-being in old age is the high prevalence of depressive symptoms and loneliness (women). Importantly also, SWB tends to be distinctly poorer in the groups of older people not included here, namely the very old, the frail living at home, and those living in assisted living environments and nursing homes.

## AGE DIFFERENCES IN ATTRIBUTION OF POSITIVE AND NEGATIVE ATTRIBUTES TO SELF AND OTHERS

A. Gilet[1], J. Studer[1], K. Iglesias[1], D. Grühn[2], G. Labouvie-Vief[1], *1. University of Geneva, Geneva, Switzerland, 2. North Carolina State University, Raleigh, North Carolina*

Attributing positive and negative attributes to self or others is a highly context-dependent process: valence of attributes, but also degree of self-relevance, level of activation and/or social distance between self and other play an important role. In order to investigate age differences in the integration of positive and negative attributes for the self or others, 174 participants from 20 to 88 years-old were asked to judge how well positive and negative attributes describe themselves, a specific close other person, and a specific distant other person. Data were analyzed using multilevel modeling which has the unique advantage of including both item and participant information in a single statistical model. Analysis yielded main effects of Age, Valence, and Arousal, as well as a significant Age x Arousal x Distance interaction: with increasing age, whatever their level of arousal, attributes are less strongly attributed to self and close others. In contrast, whereas the attribution of low arousing attributes to distant others does not change with age, the attribution of high arousing attributes decreases from the age of 60. Analysis also yielded a significant Age x Valence x Arousal interaction, indicating that attribution of high arousing positive attributes decreases with age. Personal variables such as attachment styles also were found to affect the attribution of positive and negative attributes to self and others. Findings highlight the role of context-dependent influences, such as arousal and social distance which becomes a more important factor with age and how the use of attributions changes over the lifespan.

### THE RELATIONSHIP AMONG AFFECT, ENVIRONMENTAL CONTEXT, AND GENERAL HEALTH

R.C. Intrieri, P. Goodwin, *Psychology, Western Illinois University, Macomb, Illinois*

One hundred six community-dwelling older adults participated in a study examining daily context, affective experience, and general health. The sample of 106 included 72 women and 34 men with an average age of 67.68 (SD = 9.19). Participants completed a modified version of the Day Reconstruction Method (DRM). The DRM is a stepwise procedure which asks participants to recall the previous day through construction of a short diary consisting of a sequence of episodes. For each episode, participants provided information regarding the objective situation (activity, location, companion) as well as their subjective state. In addition to the diary, participants completed a measure of overall health (the SF-12). Coefficients representing mean ratings for both positive affect and negative affect were calculated for each participant. The present analysis used multilevel random coefficients modeling using HLM 6.08 to evaluate the effects among variables representing context and positive or negative affect (level 1). We also estimated the extent to which level 1 variables varied as a function of general health (as assessed using the SF-12). For Positive Affect, statistically significant coefficients were obtained for the objective context (coefficients ranging from $b = -2.335$ to $b = 3.034$). The coefficient for general health on level 2 was also significant ($b = 1.764$; $p < .0001$). Comparable results were obtained for Negative Affect with statistically significant coefficients for contextual variables (ranging from $b = -.664$ to $b = 1.760$). The coefficient for general health on level 2 was also significant ($b = 0.574$; $p < .01$).

### AGING AND THE MALLEABILITY OF EMOTION RECOGNITION: THE ROLE OF CONTEXT

S. Noh[1,2], D. Isaacowitz[1,2], *1. Brandeis University, Waltham, Massachusetts, 2. Volen National Center for Complex Systems, Waltham, Massachusetts*

Recent evidence suggests that identifying emotion from facial expressions can be affected by the context in which the face is embedded (Aviezer et al., 2008). For example, disgusted faces are likely to be mis-categorized as expressing the context emotion when they appear in an anger context, or vice versa. We examined age differences in the role of affective context in emotion recognition. While their eye movements were monitored, participants viewed a series of face images in a self-paced manner to categorize the emotion that each face expressed. Target faces expressing anger or disgust appeared in one of three contextual conditions: congruent (e.g., disgusted face in a disgust context), incongruent (e.g., disgusted face in an angry context), or neutral (e.g., disgusted face in a neutral context). First, older showed better accuracy when identifying disgusted faces in a neutral context than did younger adults. Second, when faces appeared in a congruent context, there were no age differences in recognition accuracy for either facial expression. When faces appeared in an incongruent context, however, older adults showed a greater contextual effect in emotion recognition than did younger adults. Older adults' accuracy decreased to a larger extent regardless of the emotion expressed, as they were highly prone to identify the faces as conveying the contextually suggested emotion rather than the facially expressed emotion. Our data suggest that the role of context in emotion recognition may increase with aging. The eye movement data further suggest that age differences in the recognition of emotion can be explained by visual scanning patterns for faces.

### AFRICAN AMERICANS' EMOTIONAL HEALTH MAY BE LINKED WITH VIEWS ABOUT MAINTAINING COGNITIVE HEALTH

J.N. Laditka, J. Warren-Findlow, S.B. Laditka, *Public Health Sciences, University of North Carolina at Charlotte, Charlotte, North Carolina*

Older adults are concerned about cognitive health. Beliefs that cognitive decline is inevitable may affect emotional health negatively. Beliefs that cognitive health can be maintained may affect emotional health positively. There are few studies of beliefs about maintaining cognitive health among African Americans. Using a sample of middle aged and older African Americans, we examined associations between individuals' beliefs about their ability to maintain cognitive health and their emotional health. Data were from the 2005-2006 Milwaukee African American oversample of the second Midlife Development in the United States (MIDUS II) study (n=563). The outcome was self-reported emotional health (SREH). A 9-item self-efficacy scale measured views about ability to maintain cognitive health. Logistic regression identified the association between self-efficacy and emotional health, adjusted for current cognitive status. Controls included: demographic characteristics, income, education, self-rated memory; health conditions associated with reduced cognitive health (e.g., diabetes, hypertension, obesity); and factors that may promote cognitive health (e.g., reading, playing games, using computers). In adjusted results, each self-efficacy increase was associated with substantially higher odds of reporting better SREH (odds ratio, OR 1.59, 95% confidence interval, CI 1.16-2.17). Among controls, having poor/fair memory was associated with substantially lower odds of better SREH (OR 0.24, CI 0.13-0.46); more reading (OR 1.25, CI 1.01-1.55) or computer use (OR 1.27, CI 1.05-1.53) were associated with better SREH. Findings suggest that self-efficacy regarding cognitive health may be related to emotional health among African Americans. Health promotion efforts to maintain cognitive health among African Americans may also improve emotional health.

### DAILY FLUCTUATIONS OF MOOD AND MEMORY: A WITHIN-PERSON APPROACH TO MOOD CONGRUENCE IN YOUNGER AND OLDER ADULTS

A. Brose[1], F. Schmiedek[2,1], U. Lindenberger[1], *1. Center for Lifespan Psychology, Max Planck Institute for Human Development, Berlin, Germany, 2. German Institute für International Educational Reseach (DIPF), Frankfurt, Germany*

Emotional states such as joy and sadness may affect judgment or memory. While mood congruence (i.e., the facilitation of processing of material that is congruent with the prevailing mood) is a robust finding in mood induction studies, relatively little is known (1) on whether natural fluctuations in mood have an impact on memory processes and (2) on changes of mood congruence across the adult life span. Therefore, the first aim of this study was to investigate mood congruent memory as a consequence of daily fluctuations in mood. The second aim was to compare mood congruence in younger and older adults. We hypothesized mood congruence to be reduced in older adults because of their potentially stable preference to process positive as compared to negative material. In a microlongitudinal design, 101 younger (20-31) and 103 older (65-80) adults were tested for 100 daily sessions. Each day, participants rated their mood and worked on a verbal episodic memory task, i. e., a word memory task consisting of two word lists with positive, negative and neutral words. Results showed the presence of mood congruence for positive and mood incongruence for negative material in younger, but not in older adults. Thus, in younger adults, elevated mood was associated with better memory for both, positive and negative words, speaking for an unspecific memory-enhancing effect of positive mood. It will be analyzed and discussed whether motivation may explain the findings in younger adults, and whether motivation may play a role for the identified age group differences.

### AGE INFLUENCES GENETIC CONTRIBUTIONS TO EMOTIONAL EXPERIENCE IN DAILY LIFE

S. Gibbs[1], B. Turan[2], J. Hallmayer[1], L. Carstensen[1], *1. Department of Psychology, Stanford University, Stanford, California, 2. University of California, San Francisco, San Francisco, California*

Socioemotional selectivity theory is a lifespan theory of development postulating that, as we age, our perceived time left in life typically decreases. As a consequence of shifting time horizons, older adults are motivated to invest resources in emotionally meaningful goals and experiences (Carstensen 1993; Carstensen, Isaacowitz & Charles 1999.) In laboratory studies, older adults have been shown to allocate relatively greater attention to positive material than negative material in comparison with younger adults (i.e. a "positivity effect" on attention.) The attentional biases in older adults require cognitive control and depend on intact prefrontal cortex function (Mather & Knight, 2005.) Similar patterns of relative positivity have been found in an experience-sampling study across the lifespan (Carstensen et al 2000.) However, biological factors which may explain these lifespan differences remain poorly understood. The serotonin transporter polymorphism (5HTTLPR) is one candidate mechanism associated with the number of serotonin transporters as well as structural and functional differences in the limbic system. In younger people, the short allele confers increased risk for emotion dysregulation (e.g. Gotlib et al 2008, Canli & Lesch 2007.) Few studies have examined gene-environment interactions in older adults, though some reports suggest these interactions may be reduced with age (see Uher & McGuffin 2008 for review.) Here we investigated the contribution of the serotonin transporter polymorphism to positivity in daily emotional experience across the lifespan. A community sample of adults who participated in a 10-year longitudinal study of daily emotional experience (Carstensen et al 2000) were invited for a follow-up study to provide saliva samples for genetic analysis. Forty two volunteers (age 35-95) agreed to participate. They also completed questionnaire measures of positive and negative emotion during the follow-up assessment. As expected from prior studies, the older adults tended to report greater relative positivity in emotional experience during the emotion sampling than did younger adults (r44=0.25, p=0.09.) Participants with two long alleles (LL) reported significantly greater relative positivity in daily experience than individuals with one or two copies of the risk-conferring short allele (SS/SL) [t40=2.62, p=0.01.] However, this effect was stronger for younger participants (age 35-59: t19=-2.24 p=0.04) than for older participants (age 60-95: t19=1.14 p=0.26.) These results support the hypothesis that genetic contributions to relative positivity decline with age, in favor of cognitive or behavioral strategies optimizing emotion regulation.

### AGE DIFFERENCES IN EMOTIONAL REACTIONS: AROUSAL AND AGE-RELEVANCE MATTER

B. Streubel, U. Kunzmann, *Department of Psychology I, Life-Span Developmental Psychology, University of Leipzig, Leipzig, Germany*

Positivity effects in older adults' affective information processing are evident in task involving attention and memory. The present study examined positivity effects on the level of subjective experiences in response to pleasant and unpleasant pictures differing in arousal and age-relevance. Younger and older adults (N = 52, respectively) rated their emotional reactions to pictures from the International Affective Picture System (N = 138) in terms of pleasantness, arousal, and the intensity of sadness (i.e., an emotion highly relevant to older adults) and anger (i.e., an emotion highly relevant to younger adults). Positivity effects - defined as smaller negative emotional reactions to unpleasant pictures and greater positive emotional reactions to pleasant pictures in older as compared with younger adults - were found only for low-arousing pictures and pictures with little age-relevance (i.e., pictures eliciting anger rather than sadness). Initial analyses suggest that these findings are largely replicable in a second study that assessed emotional reactivity more objectively by means of peripherphysiological measures like heart rate and skin conductance. Together, the present evidence strongly suggests that positivity effects in old age are the result of motivationally-driven resource-demanding processes.

## SESSION 830 (POSTER)

## GRANDPARENTING

### HOW DO THE GRANDCHILDREN FEEL? ATTITUDES AND CONCERNS OF CHILDREN RAISED BY GRANDPARENTS

C. Cox, *Fordham University, New York, New York*

In the last few years there has been an abundance of studies about the concerns and issues confronting custodial grandparents. At the same time, there is a dearth of information about the needs and feelings of the children they are raising. Yet, understanding the issues encountered by the grandchildren can be important for increasing the functioning and well-being of these families. This paper presents findings from surveys completed by 23 grandchildren living in the household of a grandparent. Ages ranged from 6-18 years with the average age of 13. The children were asked to complete simple questionnaires in which among other questions, they were what they liked most and least about their living situation, if and how they would like their grandparent to change, what could improve their lives with their grandparents, what their grandparents do not know about them, and how they felt about talking with their grandparents. It is important to note that good communication was stressed as really needed. They were also asked what their grandparents need to know about them. The responses to the questions provide important insight into the lives of these grandchildren and should contribute to any program working with these families.

### GRANDPARENTS' ASSISTANCE TO ADULT DAUGHTERS: GRANDCHILDREN'S NEEDS AND GRANDPARENTAL RESOURCES

M. Monserud, P. Uhlenberg, *University of North Carolina At Chapel Hill, Chapel Hill, North Carolina*

Using data from Wave 2 of the National Survey of Families and Households, this paper examines whether grandchildren's needs and grandparental resources are predictive of grandparents' help to adult daughters which can potentially decrease inequality between advantaged and disadvantaged grandchildren. This study considers grandparent' instrumental assistance (e.g., help with household tasks, errands, and day care) and emotional support (e.g., advice) to grandchildren's mother. This paper assesses such grandparents' resources as education, health, marital status, and financial circumstances. Grandchildren's needs are defined in terms of three possible advantages available in their families – mother's marital status, mother's education, and family income. First, we investigate whether grandparent resources potentially available to grandchildren are related to their needs. Findings from cross-tabulations indicate that disadvantaged grandchildren have grandparents with fewest resources, whereas advantaged grandchildren have grandparents with most resources. Second, factors affecting level of grandparent's assistance to grandchild's mother are examined using logit regression analysis. Controlling for other variables, there is no evidence that grandparents are more likely to provide support to the grandchild's mother in disadvantaged families. More specifically, findings demonstrate that the most disadvantaged families (i.e., those in which the mother is single, not a college graduate, and poor) are the least likely to receive support from grandparents. Furthermore, grandparents with fewer resources in terms of education and marital status are less likely to assist their adult daughters. Overall, this paper suggests that grandparents do not equalize the gap between advantaged and disadvantaged children.

### HEALTH STATUS OF GRANDPARENTS CARING FOR GRANDCHILDREN IN TAIWAN

L.E. Ku, S.C. Stearns, *University of North Carolina (UNC), Chapel Hill, North Carolina*

Background: Following traditional Chinese culture, grandparents in Taiwan commonly help to care for grandchildren in three-generational families, and evidence suggests a growing trend of grandparent caregiving following Taiwan's industrialization. However, little is known about the health impact of caregiving on Taiwanese grandparents. Although research in the US has found negative health effects on grandparent caregivers, the impacts of caregiving are likely to differ in Taiwan, considering differences between the Eastern and Western family culture. Methods: Data came from 3,353 grandparent respondents in the Survey of Health and Living Status of the Elderly in Taiwan, a nationally representative survey of older adults from 1993 to 2003. Descriptive and multivariate analyses were used to estimate the national prevalence and identify main characteristics of grandparent caregivers. Results: More than 22% of all grandparents aged 57 and above reported caring for grandchildren in 2003. Among grandparent caregivers, 63% lived in multi-generational households, 25% in skipped-generational households, and 12% provided non-resident baby-sitting care. At the average age of 66, caregivers were 7 years younger and had significantly better self-rated health comparing to the non-caregivers. Conclusions: Longitudinal data from a less studied population can increase our understanding of whether caring for grandchildren has a positive health impact on grandparents of Chinese culture.

### ACCULTURATION, COMMUNICATION LEVEL, AND GRANDPARENT-GRANDCHILD RELATIONSHIPS IN CHINESE IMMIGRANT FAMILIES IN LOS ANGELES

L. Xu[1], I. Chi[2], *1. USC, Monterey Park, California, 2. USC, Los Angeles, California*

Being a grandparent is an important social role for a Chinese older adult. However, due to the acculturation of both grandparent and grandchild and thus changed communication patterns between them, close relationships between grandparent and grandchild may be different in immigrant Chinese families. A mixed method was used in this study which combined qualitative method of focus groups and quantitative method of survey. Four focus groups of Chinese immigrant older persons (aged 65 or above) residing in Los Angeles who have grandchildren under 25 years old were conducted in 2008, followed by short survey of each participant. Data were collected using a standardized discussion guide and survey questionnaire. Videotaped sessions were transcribed and independently coded by investigators and crosschecked to enhance coding validity. The results of the qualitative analysis showed that there were some communication barriers between grandparent and grandchild even though they admitted good grandparent-grandchild relationships. Most grandparents dealt with this by adjusting themselves, either through behavior or through expectation. The results of the quantitative analysis showed that grandparents reported very good relationship with their grandchild (mean= 4.5, S.D=.82, ranging from 2 to 5). Grandparent had a relative lower communication level with their grandchild through chat, call or discussion. The regression model showed that grandchildren's level of acculturation (t=-3.52, p=.004), discussion important issues with grandchild (t=2.48, p=.029), and calling each other (t=2.60, p=.023) were associated with better grandparent-grandchild relationship. The model explained 56% variance of the grandparent-grandchild relationship.

### THE RELATION BETWEEN GRANDPARENT ROLE AND PSYCHOLOGICAL WELL-BEING OF YOUNG-OLDS IN JAPAN

J. Nakahara, *Osaka University, Suita, Osaka, Japan*

This study aims to explore (1) the influence of the self-process of grandparents on frequency of contact with grandchildren and grandparent satisfaction, and (2) the influence of the self-process, frequency of contact, and grandparent satisfaction on psychological well-being. A mail survey was conducted for randomly selected people between 65–74 years of age (n = 226) living in a local city. The analysis revealed that grandparent centrality and grandparent identity influenced frequency of contact. Further, frequency of contact influenced the grandparent satisfaction of only grandfathers and grandparent identity influenced only grandmothers. In addition, only grandparent satisfaction influenced psychological well-being. The findings suggest that the influence of frequency of contact on psychological well-being brings about the grandparent satisfaction of grandfathers, while grandparent identity contributes to the psychological well-being of grandmothers.

### THE EFFECT OF GRANDPARENT'S LIVING ARRANGEMENTS ON PROSPECTIVE AGING AMONG YOUNG ADULTS

S.J. Kohn, M.M. Wood, H.P. Harrison, *Psychology, Valdosta State University, Valdosta, Georgia*

Prospective or projective aging concerns the hypothesized perceptions that people hold about their own aging in the future. In this study, we focused on the impact that social and environmental source variables such as family structure and living arrangements may have on young adult's personal views of their own aging experience in the distant future. The participants were 411 undergraduates (M-Age=23.17). Data were gathered with a self-administered questionnaire containing items on optimism and pessimism about aging, ageism, family role models, and living arrangements regarding grandparents. We were most interested in how the general makeup of the household in which participants had been raised (along with grandparents' living arrangements) might have impacted these young adult's perceptions about the aging process and older adulthood. Results showed that the young adult participants who reported significantly greater optimistic perceptions about their future as older adults; and lower ageism scores were those that were raised in either a multigenerational (beanpole) household, a custodial grandparent (skipped generation) household, or a household in which a grandparent(s) was institutionalized (e.g., in a nursing home). The lowest measures of optimism about their future as older adults came from the participants raised in household in which a grandparent(s) with a medical impairment (e.g., Alzheimer's) was a full-time family care recipient. These participants also reported that their greatest future concern (fear) about their life in old age was being burdensome (a "bother") to their family. This finding is consistent with observations of normative stress and stigma among generations of family caregivers.

## SESSION 835 (SYMPOSIUM)

### HEALTHY AGING AMONG HISPANICS IN THE SOUTHWEST: PERSPECTIVES ACROSS THE SOCIO-ECOLOGICAL MODEL OF PUBLIC HEALTH

Chair: *A.P. Herrera, Geriatric Psychiatry, UCSD, La Jolla, California*
Co-Chair: *M.L. Smith, Texas A&M School of Rural Public Health, College Station, Texas*
Discussant: *T. Prohaska, UIC School of Public Health, Chicago, Illinois*

Older Hispanics are projected to become the largest minority senior population in the U.S. by 2030. Ensuring the capacity of public health systems to respond to the disproportionate burden of chronic disease in this group is critical to promoting healthy aging, with broader implications on health policy, preventive services, and costs. The socio-ecological model of public health provides a comprehensive framework for evaluating correlates of chronic disease risk and uses a multi-pronged approach across several interlocking layers. Salinas et al's epidemiologic study reveals regional differences and heterogeneity in the biological risk factors associated with chronic disease between older Hispanics residing near the U.S.-Mexico border and those residing in other areas of the country. Smith et al investigated the influence of sexuality on older Hispanic women's perceptions of successful aging, which exemplifies the significance of expanding preconceived notions of healthy aging to include social and cultural constructs. Mier et al assessed the potential of community health centers to increase preventive health service utilization among older, impoverished, foreign-born Hispanics with diabetes. Salazar et al investigated geospacial aspects of program delivery and outcomes associated with the evidence-based Chronic Disease Self-Management Program among community-dwelling older Hispanics. These studies examine the multi-dimensional nature of Hispanic aging issues that influence public health practices contextualized by personal, cultural, and external influences on healthy aging. Drs. Thomas Prohaska and Marcia Ory, will discuss the implications of this research for the advancement of coordinated strategies and policies that promote healthy aging among Hispanics in the Southwest region.

### BIOLOGICAL RISK FACTORS IN MEXICAN ORIGIN ADULTS LIVING IN THE TEXAS-MEXICO BORDER REGION: OLD AGE DISEASES IN YOUNGER ADULTS: IMPLICATIONS FOR LONGEVITY OF FUTURE GENERATIONS

J.J. Salinas, *Epidemiology and Disease Control, UT School of Public Health, Brownsville, Texas*

The Cameron County Hispanic Cohort (CCHC) study is compared to National Health and Nutrition Examination Survey (NHANES 2003-2006) data to determine the relative disease risk in US-Mexico border residing Mexican Americans. A compilation score of biological risk was created using nine biomarkers associated with chronic disease. Regression analysis was conducted to predict biological risk factors by immigration and socioeconomic status controlling for covariates. Results indicate that at every age group US-Mexico border residing Mexican Americans have on average one biological risk factor more than the NHANES sample. Although an immigrant advantage exists at younger (18-29) and older age (70+), immigrants living in the border region have greater on average biological risk factors than the NHANES sample. The results from this study demonstrate the need for regional comparisons of the biological process of aging for Mexican Americans in order to bring to light health disparities that exist within this ethnic group.

### EXAMINING RELATIONSHIPS BETWEEN SEXUALITY AND SUCCESSFUL AGING AMONG HISPANIC/LATINO POST-MENOPAUSAL WOMEN

M.L. Smith[1], A.P. Herrera[2], M. Ory[1], D. Jeste[2], *1. School of Rural Public Health, Texas A&M Health Science Center, College Station, Texas, 2. University of California - San Diego, San Diego, California*

Little is known about sexuality and aging among Hispanics. Objective: Examine the influence of sexuality on perceived successful aging and quality of life (QOL) among older post-menopausal Hispanic women. Methods: 121 Hispanic women (mean age=69.9 years) from the San Diego Women's Health Initiative/Successful Aging study were examined. Descriptive, bivariate, and logistic regression analyses were conducted. Results: 44% of Hispanics reported having intercourse in the previous year; 25.9% in the last week. Women perceiving themselves to be aging most successfully were significantly more satisfied with their QOL and sexual activity and desired sex a lot of the time. Women satisfied with their QOL were significantly more likely to have sex weekly and be satisfied with their sexual activity some of the time. Conclusion: Perceptions of successful aging and QOL are associated with sexuality. More investigation is needed to identify factors contributing to the frequency and satisfaction of sexual practices among Hispanics.

### GEOSPATIAL INFLUENCE ON PARTICIPATION AND SUCCESS IN A CHRONIC DISEASE PROGRAM IN SOUTH TEXAS

C.I. Salazar[1], M.L. Smith[2], M. Ory[2], A. Wilson[2], S. Ahn[2], *1. Clinical Outcomes and Program Evaluation, Univeristy Center for Community Healht/University Health System, San Antonio, Texas, 2. School of Rural Public Health, Texas A&M Health Science Center, College Station, Texas*

Despite documented health benefits of evidence-based disease management programming, less is known about factors influencing program participation and success for Hispanics. To assess the impact of geospatial and social characteristics in predicting ethnic differences in CDSMP participation and success. Baseline and 6-month follow-up data were examined from CDSMP offered in Bexar County, Texas (n=464). Geocoded data were derived from participant and site Zip codes and analyzed utilizing logistic regression. Most participants were Hispanic/Latino (58%) with a completion rate of 66%. Hispanic participants were younger, less educated, and resided in less affluent areas than their non-Hispanic white counterparts. Predictors of attendance included miles traveled and type of CDSMP host site. Participant outcomes included reduced usual activity interference. Program delivery location can influence health outcomes and eliminate attendance barriers. For Hispanics, offering CDSMP close to home with specific community partners will increase program access and utilization.

### CORRELATES OF HEALTHCARE UTILIZATION AMONG BORDER MEXICAN AMERICAN SENIORS WITH DIABETES

N. Mier[1], X. Wang[3], M.L. Smith[2], E. Villarreal[1], M. Alen[1], M. Ory[2], *1. Texas A&M School of Rural Public Health, McAllen, Texas, 2. Texas A&M School of Rural Public Health, College Station, Texas, 3. UT Panam, Edinburg, Texas*

Access to healthcare is important for managing diabetes; however, little is known about predictors of healthcare utilization among minorities. Objective: To determine personal and social correlates to healthcare utilization among border Hispanic seniors with diabetes. Methods: A community assessment survey (n=249) was conducted. Descriptive and multiple regression analyses were applied. Recruitment settings included a clinic, senior centers, and colonias. Results: Older Hispanics with diabetes residing in a colonia and uninsured had less access to healthcare than their counterparts. Significant correlates to physician utilization were gender, physician visits in Mexico, nativity, insurance, physician fees, obesity, colonia residency, and marital status. Significant correlates to emergency room visits (ER) were age, insurance, heart attack history, and retinopathy. Conclusions: Border older Hispanics may be relying on community clinics and ERs to treat their diabetes. Public health policies are needed to promote diabetes self-management among this population.

## SESSION 840 (PAPER)

## IMPACT OF DEMENTIA

### THE IMPACT OF DEVELOPING DEMENTIA ON THE SELF

L.S. Caddell, L. Clare, *Psychology, Bangor University, Bangor, United Kingdom*

Past research has concentrated on aspects of self and identity in people with dementia, but little research has focussed specifically on the personal experience of how developing dementia impacts upon self and identity, despite the implications for communication, support and care for people with dementia and their carers. The aim of this study was to explore in depth how people with dementia feel about the impact of the illness on their sense of self and their identity. Ten people in the early stages of dementia were interviewed separately, and transcripts were analysed using Interpretative Phenomenological Analysis. A number of themes emerged regarding the maintenance or changes in the self that participants were experiencing following the onset of dementia. These included the conflicting themes of, 'I'm still the same person' and 'an inevitable change', in addition to reflections on the future, captured by the themes 'that will never change' and 'what will be in front is another thing'. These results suggest a tension between acknowledging changes in the present and possible changes in the future, whilst maintaining that overall there is a sense of continuity in the experience of self, and the expectation that this will not change over time despite the effects of dementia. These results provide a useful foundation for thinking about what type of support might be helpful for people in the early stages of dementia with respect to supporting personhood and well-being.

### MAKING SENSE OF NON-SENSE: NARRATIVES OF MILD COGNITIVE IMPAIRMENT

R.L. Beard, T.M. Neary, *Department of Sociology & Anthropology, College of the Holy Cross, Worcester, Massachusetts*

As the number of seniors continues to rise, we find ourselves in the midst of an aging society with various economic, cultural, and political challenges. While medical innovations and improved disease prevention have certainly enhanced the overall quality of life for older people, Alzheimer's disease (AD) remains stigmatized and is assumed to be a death sentence for those diagnosed. Consequently, people with Alzheimer's are often deemed incapable (and perhaps unworthy) of contributing to the social discourse surrounding their illness experience. This study analyzed qualitative interview data from 18 people diagnosed with the potential preclinical phase of AD known as amnestic mild cognitive impairment (MCI). Using grounded theory methods, analysis revealed common themes of uncertainty and misinformation concerning definitions of memory loss, MCI, and AD as well as distinctions between normal aging and dementia. The interactional tensions resulting from this confusion over the terminology and prognosis mirror the lack of scientific consensus about the nosology and appropriate treatment regimen for MCI. Such ambiguity creates social and psychological difficulties in the lives of diagnosed individuals. The implications of these findings for research and practice are noteworthy as it is crucial to understand the perspectives of those most intimately affected, including how they interpret the news they are given and the effects the condition has on their health practices, social interactions, and everyday lives. In order to inform interventions, improve clinical encounters and quality of life for diagnosed individuals, and provide appropriate services and treatment options, narratives of MCI must be widely surveyed.

### THE RELATIONSHIPS AMONG PERCEIVED STIGMA AND QUALITY OF LIFE OUTCOMES OF PERSONS WITH DEMENTIA

S.C. Burgener[1], K.C. Buckwalter[2], R. Riley[2], M. Liu[2], C.J. Einhorn[1], *1. Biobehavioral Health Nursing, University of Illinois College of Nursing, Urbana, Illinois, 2. The University of Iowa College of Nursing, Iowa City, Iowa*

Progressive neurological diseases, such as Alzheimer's Dementia (AD), are prevalent conditions that involve manifestations believed to elicit stigma, such as changes in behavior and competence. Previous studies support the susceptibility to and impact of stigma on persons with dementia (PwD) including: awareness of responses of others, mental changes associated with dementia, negative self-attributes of persons in early stage dementia, and anecdotal accounts of experienced stigma in PwD. Currently, a longitudinal study (4 assessment points over18 months) is being conducted to examine the: 1) 'natural history' of perceived stigma in the early stages of AD, vascular, or mixed dementia; 2) relationships among background variables, perceived stigma, and quality of life (QoL) outcomes (depression, self-esteem, health, activity participation, behavioral symptoms) in PwD; and 3) effects of the primary caregiver's perceived stigma on QoL outcomes in PwD. The study sample represents a typical population of PwD, with a mean age of 80 (range 63-105), mean education of 13.3 years, and mean length of diagnosis of 14 months. Findings from a subsample (n=33) of the total sample of PwD (N=60) reveal significant relationships among perceived stigma of PwD and physical health (r= -.47), self-esteem (r= -.37), anxiety related to dementia (r= .64), and social support (r= -.42). Moreover, the family caregivers' perceived stigma was found to be related to anxiety in the PwD (r= -.39). Findings from the total sample for the initial (T1) assessment will be presented. Findings to date increase our understanding of the significance of perceived stigma to outcomes in PwD.

### THE FIRST TRANSITION IN DEMENTIA CARE: THE INTERFACE BETWEEN COPING STRATEGIES AMONG OLDER ADULTS WITH MEMORY PROBLEMS AND EXPERIENCE OF NATIONAL HEALTH SERVICE (NHS) MEMORY SERVICES

M. Downs[1], E. Argyle[1], P.C. Baldwin[1], R. Fortinsky[2], *1. University of Bradford, Bradford, United Kingdom, 2. Connecticut Centre on Aging, Farmington, Connecticut*

Background: People respond to living with memory problems in different ways, with some predominantly relying on self-maintaining and some on self-adjusting coping strategies. England's National Dementia Strategy strongly encourages people with memory problems to seek early diagnosis and effective intervention, primarily through locally-available memory services. In the recently-emergent literature on memory services' user experiences, no research has compared self-reported experiences based on type of coping strategies. Accordingly, we examined the association between type of coping strategies and expectations and benefits of memory service use over time, from the perspective of service users. Methods: Qualitative interviews were conducted at three points in time with 19 service users: immediately preceding; immediately after; and 6 weeks after the first appointment. Results: Unlike service users with self adjusting coping strategies, service users with self maintaining coping strategies did not expect to benefit from the memory service. Neither group knew what to expect from the initial appointment, leading to anxiety and apprehension. After the first appointment, both groups reported greater awareness of memory problems and reassurance and relief, although most had had a negative experience of the testing process. After the second appointment both groups reported a lack of satisfaction with the service. Implications: Implications for policy, practice and research are discussed.

## SESSION 845 (PAPER)

## LENGTHS OF LIFE

### MARITAL STATUS DIFFERENTIALS IN ACTIVE LIFE EXPECTANCY IN THE UNITED STATES

M. Hidajat[1,2], M. Hardy[1], M. Hayward[3], *1. Pennsylvania State University, University Park, Pennsylvania, 2. University of Utah, Salt Lake City, Utah, 3. University of Texas at Austin, Austin, Texas*

Although the profound implications of marriage on health and mortality is well known, less is known about the lifetime consequences of marital status on both health and mortality at the population level. In this paper, we use multistate life table models to calculate active life expectancy by marital status. This approach allows us to examine how marital status operates on the onset of significant health problems, improvements in health, and whether marital status continues to affect health—especially mortality—once poor health has ensued. In substantive terms, this study assesses whether married person are able to delay the onset of health problems, get better faster, and also delay mortality after health problems have occurred. We use data from the AHEAD cohort of the Health and Retirement Study (HRS), a nationally representative longitudinal survey of Americans who were born before 1924 and followed from 1995 to 2007. Using ADLs to measure functional limitations, we define active life expectancy as having no difficulty performing one or more ADL activities, such as walking across a room, dressing, bathing, eating, getting in and out of bed, and using the toilet. Our core hypothesis is that marriage exerts a persistent effect throughout adulthood such that married persons' lengthier lives reflect a postponement of poor health and a compression of the years lived in poor health. The ways in which these processes are gendered are theoretically ambiguous, and empirical work will provide a much needed foundation for future theoretical developments.

### THE ROLE OF HEALTH AND HEALTH BEHAVIORS IN DETERMINING SURVIVORSHIP AMONG THE U.S. OLDEST OLD

H. Beltran-Sanchez, J.A. Ailshire, *Ethel Percy Andrus Gerontology Center, University of Southern California, Los Angeles, California*

Despite increasing numbers of people reaching old age, little is known about the factors that determine survivorship into oldest-old age (90+ years) among those who have survived to old age (65+ years). Research on the oldest-old has typically focused on national level studies of mortality and survivorship based on vital statistics records. However, individual-level factors play a crucial role in understanding the health dynamics of the oldest-old population, particularly in relation to survivorship. In this paper we examine how socioeconomic status, demographic characteristics, health status, and health behaviors are associated with oldest-old mortality and survivorship among people who have survived to old age. We analyzed data on 16,521 adults aged 65 years and older from the 1990 and 1991 National Health Interview Survey with mortality follow-up through December 2002. Results from a proportional hazard model controlling for age, sex, education, activity limitation, and exercise habits show that there remains a gradient in the hazard of death by educational level, and that activity limitation and exercise status play an important role in mortality at older ages. People with less than high school and those with high school education experienced about 24% and 19% higher hazard of death, respectively, relative to those who completed college or more. Having some activity limitation increased the hazard of death by about 56%, while exercising reduced it by about 22%. Using estimates from this model we constructed life tables to determine average life expectancy associated with different combinations of sociodemographic and health characteristics.

### SIMILARITIES AND DIFFERENCES IN HEALTH EXPECTANCIES ACROSS THE LIFECOURSE IN EUROPE

C. Jagger[1,2], C. Gillies[2], J. Robine[3], *1. Institute for Ageing and Health, Newcastle University, Newcastle upon Tyne, United Kingdom, 2. University of Leicester, Leicester, United Kingdom, 3. INSERM/CERMES, Paris, France*

European life expectancy is increasing though not uniformly throughout all 27 EU countries. Moreover healthy life expectancy, as measured by the new EU structural indicator Healthy Life Years (HLY), is even more variable. In 2005 the range in HLY at age 65 was 9.7 years for men, from 3.4 years (Estonia) to 13.1 years (Denmark), and 10.7 years for women, from 3.4 years (Estonia) to 14.1 years (Denmark), wider than the total remaining years of life at age 65 of 12.5 years (Latvia) to 17.7 years (France) for men and 4.9 years for women, from 17.2 years (Latvia) to 22.0 years (France). However it is not clear whether the gaps are at younger or older ages or both, and whether similar results hold for other health measures than the Global Activity Limitation Indicator (GALI) on which the HLY is built. In this paper we calculate partial life expectancies for ages 16-34, 35-54 and 55-74 and the associated health expectancies from the three health measures (GALI, chronic morbidity and self-rated health) in the Statistics of Income and Living Conditions (SILC) over the period 2005-2007. We then use cluster analysis to explore similarities and differences in the profiles of health expectancies over the lifecourse between the 25 countries of the European Union.

### SELECTIVE MORTALITY AND LIFE COURSE RESEARCH: CONSEQUENCES, AND SOLUTIONS

S.M. Lynch, *Sociology, Princeton University, Princeton, New Jersey*

Rates of mortality vary substantially across individuals, so that members of a birth cohort who survive to be interviewed in a survey become an increasingly select subgroup of their original birth cohort as the cohort ages. The result is that estimates of even fixed characteristics for the cohort change across age, as do regression coefficients. These consequences are particularly pronounced when the variable of interest is related to the propensity to die. Some of the consequences of "selective mortality" have been well-known for at least three decades, but outside of demography and health research, relatively little attention has been paid to the issue. Yet, selective mortality may affect results of studies in a wide variety of substantive areas, especially when a life course hypothesis is investigated. In this paper, (1) I present evidence that selective mortality occurs, (2) I show the consequences of selective mortality in terms of influencing parameter estimates and conclusions regarding hypotheses, (3) I assess the usefulness of remedies that have been proposed and used in the literature, and (4) I develop a new approach to handling selective mortality.

# SESSION 850 (PAPER)

## LIFE HISTORY'S EFFECT ON COGNITION

### HISTORY OF SEXUAL ASSAULT IS ASSOCIATED WITH EARLIER DECLINES IN EXECUTIVE FUNCTIONING IN OLDER ADULTS WITH APOE-4

A. Petkus[1], J. Wetherell[2,4], M.B. Stein[2,3], L. Liu[3], E. Barrett-Connor[3], *1. San Diego State University / University of California, San Diego Joint Doctoral Program in Clinical Psychology, San Diego, California, 2. Department of Psychiatry, University of California, San Diego, San Diego, California, 3. Department of Family and Preventive Medicine, University of California, San Diego, San Diego, California, 4. VA San Diego Healthcare System, San Diego, California*

Experiencing a sexual assault (SA) has been associated with deficits in executive functioning (EF) in younger adults, although the long-term effects of SA on EF in older adulthood are not known. APOE ε4 genotype is also associated with increased risk for deficits in EF. Although both SA and APOE ε4 genotype may be associated with declines in EF, no studies have investigated how these risk factors may interact over time. Over an interval of 12 years, 1,383 older adults were assessed at approximately 3-year intervals. APOE ε4 data were available for a subsample of 846. Assessments included Trails-B and verbal fluency tests of EF, as well as a question about past history of sexual assault. Mixed-effects models were used to first examine the relationship between SA and EF over time. A second mixed-effects regression examined whether APOE ε4 genotype moderates the relationship between SA and EF over time. SA by itself was not associated with more or earlier decline in EF over time. For Trails B, there was a significant interaction between SA exposure and APOE ε4 genotype, in that those who experienced both a SA and had the APOE ε4 genotype experienced greater declines in performance earlier in life. Having both SA and APOE ε4 appears to be associated with faster decline on the attention, visuotracking and psychomotor speed components of EF. Explanations as well as clinical implications of these findings are discussed.

### PSYCHIATRIC HISTORY AND COGNITION TRAJECTORIES IN LATER LIFE: THREE COMPONENTS OF COGNITION

M. Brown, *Syracuse University, Syracuse, New York*

Advocates of the life course perspective suggest that cumulative inequality affects later-life cognitive function, and that a history of psychiatric problems may be detrimental to cognition among individuals at risk of experiencing cumulative disadvantage. Psychiatric conditions are more prevalent among disadvantaged groups, who may also be at risk of experiencing cognitive decline in later life. Therefore, it is important to explore the relationships between sex, race/ethnicity, childhood disadvantage, psychiatric history, and cognitive function. This study addresses the following hypotheses: 1. Individuals with a history of psychiatric problems will have lower cognitive function and/or a unique trajectory of cognitive function with age, for three different components of cognition – total recall, fluid intelligence, and crystallized intelligence. 2. This relationship will differ based on the component in question and on an individual's ascribed and early life characteristics. This study uses six waves of Health and Retirement Study data to examine influences on three components of cognitive function. Data are analyzed using growth curve models, controlling for demographic, health behavior and health status variables. Psychiatric history is significantly related to each of the three components of cognitive function, but is not related to decline in all components. Each component also has different relationships with sex and race/ethnicity and childhood disadvantage. These effects are partially mediated by demographic and health characteristics. These findings demonstrate that cumulative disadvantage and psychiatric history interact to shape different aspects of later life cognition, and can enhance our understanding of cognitive decline experienced in later life by disadvantaged groups.

### MINI-MENTAL STATE EXAMINATION IN MEXICAN ELDERLY. THE EFFECT OF AGE, SEX AND EDUCATIONAL LEVEL

E. ArIas-Merino[1], G.G. Ortiz[2], R.M. Meda-Lara[1], M.J. Arias-Merino[1], N.M. Mendoza-Ruvalcaba[1], J. Cueva Contreras[1], *1. Universidad de Guadalajara, CUCS, Depto. Salud Pública, Guadalajara, Jalisco, Mexico, 2. Centro de Investigaciones Biomédicas de Occidente, IMSS, Guadalajara, Jalisco, Mexico*

Introduction. For the MMSE is documented that age and low education level, are associated with poor execution of the test. In Mexico, there are no reference population normative values for the MMSE. Objective. To show normative values in relation to age, gender and education level of MMSE score in Mexican elderly. Materials and Methods Based on the Prevalence of Dementia Project in Jalisco (CONACYT-9997), MMSE score was calculated by percentiles ranked by age, education and gender. We excluded 162 subjects with a dementia diagnosis, cerebral vascular disease and severe sensory issues. Results. The study included 2409 subjects, age 60-110 years old, 61.1% female, 26.6% no education. Correlation between MMSE score: age (r=0.345, p=0.01), gender (r=0.043, p=0.05) and education (r=0.536, p=0.01). Percentiles are presented by educational level, age group and sex (M men and W women). Percentile 10: No education, 60-69(M19/W17), 70-79(M17/W16), 80-110(M15/ W14). Education level: 1-4 years, 60-69(M23/W21), 70-79(M20/W19), 80-110(M15/ W16). Education level: 5-8 years, 60-69(25), 70-79(22), 80-110(19). Education level: 9 and more years, 60-69(27), 70-79(24), 80-110(23). Conclusions: MMSE total score declines as age increases, increases with higher levels of education. Higher scores were observed in men.

### IMPACT OF INDIVIDUAL AND SPOUSAL PERSONALITY CHARACTERISTICS ON MEMORY

J. Blaskewicz Boron[1], L. Ryan[2], *1. Psychology, Youngstown State University, Youngstown, Ohio, 2. University of Michigan, Ann Arbor, Michigan*

Much research has documented relationships between individuals' personality and cognitive ability. Extraversion, conscientiousness, and openness have all been positively associated with memory in older adults, while neuroticism has demonstrated a negative relationship. Prior research has also suggested older adults may benefit on memory tasks by collaborating, such as with a spouse. However, the impact of spousal personality on cognition has not been investigated. The current study sought to examine the interaction of individual and spousal personality characteristics on memory in a large sample of married couples (N=1924 couples; age range: 30-96 years; mean age=65) from the 2006 wave of the Health and Retirement Study using Actor-Partner Interdependence models with SAS PROC MIXED. Results indicated that individual ($p<0.001$) and spousal pessimism ($p<0.01$), individual openness ($p<0.001$), and the interactions of individual pessimism and spousal openness ($p<0.05$), and individual conscientiousness and spousal pessimism ($p<0.01$), were significant predictors of memory after controlling for age, education and health. The individual pessimism, spousal openness interaction revealed low pessimism individuals scored higher on verbal memory, regardless of spousal openness. High pessimism individuals with high openness spouses scored lower on memory than those individuals with spouses low on openness. For the individual conscientiousness, spousal pessimism interaction, low spousal pessimism appeared to positively impact memory, regardless of individual conscientiousness. However, high spousal pessimism was especially detrimental to those individuals low on conscientiousness. Thus, although some individual personality characteristics may negate spousal personality influences on memory, the interaction of individual and spousal personality characteristics can impact memory in adulthood.

## SESSION 855 (SYMPOSIUM)

### MIXED METHODS RESEARCH ON HEALTH SELF-MANAGEMENT IN A MULTI-ETHNIC POPULATION OF OLDER RURAL ADULTS

Chair: *S. Quandt, Public Health Sciences, Wake Forest University School of Medicine, Winston-Salem, North Carolina*
Co-Chair: *T.A. Arcury, Public Health Sciences, Wake Forest University School of Medicine, Winston-Salem, North Carolina*

This session focuses on studies from rural North Carolina on the health self-management practices of older adults. Most older adults have been diagnosed with at least one chronic condition, and many have multiple diagnoses. They deal with symptoms of these chronic conditions, as well as occasional acute conditions, on a regular basis, drawing on medical care and self-care, with input from informal and formal supports. The papers in this session focus on self-management practices of adults in a population that includes significant numbers of minority (African American and American Indian) elders and in which many older adults have incomes below the poverty line. The session's overall goal is to illustrate the role of qualitative data for developing innovative research designs for the study of health self-management in older populations. The first two papers come from a study of the place of complementary therapies in health self-management. The first paper illustrates how herb use, with both traditional and contemporary characteristics, is integrated into health self-management, while the second paper shows how a daily diary study was implemented to capture the subtleties of self-management. The last three papers focus on diabetes, with one drawing on qualitative data to demonstrate how older adults' perceptions of their self-management skills differ from biomedical standards and another highlighting the role of fear of consequences in displacing older adults' concerns for their self-management. The final paper shows how older adults' discourse about diabetes is used to construct a tool for measuring holistic belief systems about diabetes.

### THE PLACE OF HERB USE IN HEALTH SELF-MANAGEMENT AMONG RURAL OLDER ADULTS

K.P. Altizer, S. Quandt, J.G. Grzywacz, R.A. Bell, E.P. Stoller, T.A. Arcury, *Wake Forest University School of Medicine, Winston-Salem, North Carolina*

This study provides a conceptually-based analysis of the role of traditional and contemporary herbs in older adults' health self-management. 62 African American and white older adults completed qualitative interviews describing the forms of herbs used, sources of information about herbs, interpretations of health that lead to herbs use, and the initiation and suspension of herb use in response to symptoms or chronic conditions. Traditional herbs are native to the region or have been traditionally cultivated; most often taken raw or boiled to produce a tea; and used for treating acute, mild symptoms. Contemporary herbs are prepared as pills, extracts, or teas; purchased at local stores or ordered by catalog or internet; and used for health promotion, illness prevention or treatment of chronic conditions. Herbs are widely used among older adults; we differentiate the types of herbs they use and their reasons for herbs use. Grant R01-AT003635

### USING DAILY DIARIES TO DOCUMENT USE OF COMPLEMENTARY AND OTHER THERAPIES FOR SPECIFIC SYMPTOMS AMONG RURAL OLDER ADULTS: STUDY DESIGN AND ILLUSTRATIVE RESULTS

T.A. Arcury, R. Neiberg, K.P. Altizer, R.A. Bell, W. Lang, H. Nguyen, S. Quandt, *Dept of Family and Community Medicine, Wake Forest University School of Medicine, Winston-Salem, North Carolina*

Older adults use complementary therapies (CTs), yet few studies document daily CT use for treating specific symptoms. We describe the design of a daily diary study that delineates CT use for common symptoms. We recruited 200 community dwelling older adults, including African American and white men and women. Participants completed a baseline interview and up to six sets of monthly interviews for three consecutive days that addressed the presence and treatment of 40 common symptoms. Participants provided data for 3,070 days. This presentation focuses on four symptoms: Join Pain, Indigestion, Low Energy, and Sort Throat. CT use varied by symptom; e.g., home remedies were used for 0.2% of the days on which low energy was reported but on 20.5% of days when sort throat was reported. A daily diary approach implemented with older adults provides detailed data of the purposes for which CTs are used. Grant R01-AT003635.

### DIABETES SELF-MANAGEMENT AMONG RURAL OLDER ADULTS: PERCEIVED MASTERY AND ACTUAL BEHAVIOR

T. Kohrman[1], C. Chapman[1], T.A. Arcury[2], S. Quandt[1], *1. Public Health Sciences, Wake Forest University School of Medicine, Winston-Salem, North Carolina, 2. Wake Forest University School of Medicine, Winston-Salem, North Carolina*

This study examines diabetes management experiences of 74 African American, American Indian, and white older adults in rural North Carolina. Data from in-depth interviews indicate that most participants believe they have mastered skills to manage diabetes effectively. However, the data suggest that these individuals over-estimate their self-management. Most describe efforts to eat properly, but few have specific diet plans, and they discuss vague notions of what to do. Some dietary practices contrast sharply with biomedical self-management approaches (e.g., consuming sour foods to “cancel out” elevated blood sugar). While a handful take advantage of local fitness centers or take long walks, most fail to engage in regular, sustained physical activity. Although most use medications as directed, some report taking additional medication to compensate for excessive eating. Others stop and start medications according to the symptoms experienced. This analysis suggests that many older rural adults have not mastered self-management skills. Funding: AG17587

### WHAT OLDER RURAL ADULTS FEAR THE MOST ABOUT DIABETES: IMPLICATIONS FOR SELF-MANAGEMENT

C. Chapman[1], T.A. Arcury[2], S. Quandt[1], *1. Wake Forest University School of Medicne, Winston Salem, North Carolina, 2. Wake Forest University Department of Family Medicine, Winston Salem, North Carolina*

This paper is based on 74 in-depth interviews conducted with African American, Native American and white adults, 60 and older who live in rural counties and have had diabetes for at least two years. When asked what they fear the most about diabetes, responses focused on major complications that could limit their ability to carry out normal activities, such as amputation or blindness. These fears dictated their self-management activities, as they focused specifically on actions that they believed would prevent their fears being realized, including examining their feet daily or having an annual eye examination. They attributed less importance to those self-management activities recommended by physicians to control blood. This paper explores the origins of fears, whether elders’ daily activities will prevent the feared complications, and the disconnection between elders’ self management practices and the management of their disease as a whole. Funding: AG17587

### IDENTIFYING COMMON SENSE MODELS OF DIABETES IN A MULTI-ETHNIC SAMPLE OF RURAL OLDER ADULTS

S. Quandt, J.G. Grzywacz, E. Ip, C. Chapman, J. Kirk, R.A. Bell, S. Saldana, T.A. Arcury, *Public Health Sciences, Wake Forest University School of Medicine, Winston-Salem, North Carolina*

This study was designed to identify “common sense models” (CSMs) of diabetes in a multi-ethnic (African American, American Indian, white) population of older rural adults. CSMs incorporate beliefs and knowledge about an illness, and shape illness-related behavior. However, no instruments exist to allow holistic measures of CSMs. Ninety-four belief statements concerning diabetes were extracted from a series of 74 qualitative interviews. A separate sample of 600 from the same population rated their agreement with each statement, and provided a blood sample to assess glycemic control (A1C). Latent Class Analysis was used to first identify within-domain (e.g., diabetes etiology) latent classes. These were then subjected to a second, categorical version of LCA. Coherent CSMs of diabetes emerged, allowing individuals to be classified according to their belief structure and the association of A1C with belief structure to be demonstrated. Such an approach may be useful in promoting effective disease self-management. Funding: AG17587.

## SESSION 860 (PAPER)

## MOTHER/DAUGHTER RELATIONSHOPS

### HOW THE QUALITY OF INTERGENERATIONAL RELATIONSHIPS MODERATES VALUE TRANSMISSION BETWEEN PARENTS AND THEIR ADULT CHILDREN OVER THE LIFE COURSE

J. Min, M. Silverstein, *Davis School of Gerontology, University of Southern California, Los Angeles, California*

Literature consistently shows that parental values influence children’s values but less is known about the persistence of value transmission over the life course and the role of family dynamics in the process. This research examined how the quality of intergenerational relationships in adulthood moderates the transmission of two different value orientations: religious attitudes and gender role ideology. We hypothesized that intimacy in mother-child relationships would enhance value transmission between the generations. We addressed our research question using 1971 and 2000 waves of the Longitudinal Study of Generations (LSOG). The sample consisted of 268 mother-child dyads, where mothers were measured in 1971 and their children were measured in 2000. Mothers averaged 43 years old and their offspring averaged 48 years old at measurement, roughly equating their ages. We found statistically significant intergenerational transmission with regard to both values. Parents contributed more to their children’s religious attitudes ($R2=.22$) than to their gender role ideology ($R2=.05$). Quality of the mother-child relationship strengthened the transmission of gender role ideology ($t=2.397$, $P<.05$) but not of religious attitudes. Results suggest that the long-term strength of intergenerational value transmission and the role of intimacy as a facilitator of transmission vary according to type of value considered. We discuss the central role of parents on their children’s value orientations as a relational and a life course process.

### SUPPORT BETWEEN ADULT DAUGHTERS AND THEIR MOTHERS, RELATIONSHIP QUALITY, AND LIFE SATISFACTION

M. Friedlmeier, W. Friedlmeier, *Grand Valley State University, Allendale, Michigan*

Due to increased life expectancy in industrialized countries, parents and children share more time together. Irrespective of the existence of a social security system, the exchange of support remains important in the parent-child relationship throughout the whole life (Arber & Attias-Donfut, 2000). This intergenerational exchange is comprised of emotional, instrumental, and financial support, and represents a major aspect of the model of intergenerational functional solidarity developed by Bengtson and colleagues (e.g. Bengtson & Roberts, 1991). The main goal of this study was to test one assumption of this model, namely that a balance between support provided and received will increase the quality of the parent-child relationship (Bengtson & Roberts, 1991), and may also be relevant for well-being, especially among the older generation. Eighty three dyads of middle aged women (M = 45.17 years, SD = 5.68) and their mothers (M = 67.92 years, SD = 6.00) from a large city in the Midwest were interviewed. Cross-sectional self report data with respect to the extent of different forms of support they give and receive, relationship quality, and life satisfaction were assessed. Preliminary analyses show that a reciprocally balanced perception of the give-and-take between adult daughters and their mothers led to greater intimacy and fewer conflicts between them. Also, the results suggest that receiving support per se is not always beneficial for the recipient. The findings will be discussed within the framework of parent-child relationship in later life.

### THE DEVELOPMENT OF THE MOTHER-IN-LAW STYLES INDICATOR (MILSI)©

M. Turner, W.C. Bailey, *Human Development and Family Sciences, University of Arkansas, Fayetteville, Arkansas*

Women are the kinkeepers in the family. One key dimension of this role is the development of quality relationships between the mother-in-law (MiL) and her daughter-in-law (DiL). Yet few measures have been developed to assess the unique style of relating between MiLs and DiLs. The current research indicates the style and quality of this relationship can vary considerably. The MiLSI is a self-assessment of a MiL's perception of her style of relating to her DiL. Using surveymonkey.com, data were collected from 254 MiLs who had a mean age of 57.6.years. There were 50 items on the initial questionnaire with five possible responses ranging from "never like me" to "always like me." The items were reduced to 35 following exploratory factor analysis. Five factors were found with eigenvalues higher than 2.0, explaining 50.6% of variance. The resulting factors were labeled Utilitarian, Combative, Traditionalist, Harmonizer, and Engager. For example, a Utilitarian MiL remains aloof and seldom interacts with her Dil. The Engager perceives her DiL as capable of making contributions to her well-being, is open with, and inclusive of her DiL. Each respondent's style was determined by adding 7 items together creating 5 style scores ranging from 7 to 35. Using the highest style score, MiLs were assigned a primary style. A secondary style was assigned using the second highest score. Additional research using MiLSI© is needed with a random sample of different populations. The instrument is available for others to use for research.

### IS MARRIAGE ALWAYS GREEDY? THE EFFECTS OF IN-LAW RELATIONSHIP QUALITY ON MOTHER—ADULT CHILD RELATIONS

J. Suitor[1], J. Sechrist[1], S. Kim[1], K. Pillemer[2], *1. Purdue University, West Lafayette, Indiana, 2. Cornell University, Ithaca, New York*

Both classic and contemporary scholars have identified marriage as a "greedy institution" in which adult children reduce intergenerational ties due to the demands of marriage. However, studies have not considered how parents' relationships with their children-in-law influence the parent-adult child relationship. We suggest that the degree of "greediness" of marriage (i.e. reduced closeness and contact with married children) will be higher in cases where there is high conflict with the child-in-law. Using reports on 2,143 adult-children from 566 mothers from the Within-Family Differences Study, we extend the study of in-law relationships to examine the influence that these relationships have on relations between mothers and their adult children. Multi-level models indicate that high in-law conflict is related to lower closeness and less frequent interaction between mothers and adult children when compared to unmarried children. In contrast, when there is low tension and conflict in the in-law relationship, mother-adult child relations are actually closer compared to relations between unmarried children and their mothers. These findings indicate that marriage is greedy only when there is conflict between mothers and children-in-law; whereas positive in-law relationships are actually related to stronger mother-child ties.

## SESSION 865 (SYMPOSIUM)

### NONPHARMACOLOGIC VERSUS PHARMACOLOGIC INTERVENTIONS FOR BEHAVIORAL AND PSYCHIATRIC SYMPTOMS IN DEMENTIA: TRANSITIONS IN CARE PRACTICES

Chair: *C. Camp, Hearthstone Alzheimer Care, Woburn, Massachusetts*
Co-Chair: *A. Snow, Cntr for Mental Health & Aging/Psychology, University of Alabama/Tuscaloosa VAMC, Tuscaloosa, Alabama*

Behavioral and psychiatric symptoms (BPS) associated with dementia are highly prevalent and affect quality of life. Traditionally, pharmacologic treatments have received more emphasis and use for BPS, but there in now strong evidence that these treatments have only modest efficacy and significant risk. An important transition occurring in the delivery of quality care to individuals with dementia is the transition from a traditionally pharmacologic-focused approach to the use of non-pharmacologic treatments. This symposium will begin with a sociological view, examining why pharmacologic approaches have been popular and ways in which societal knowledge might popularize non-pharmacologic approaches. Moving to an epidemiologic view, we will present findings of a longitudinal study of the development of aggression and how the identification of antecedents of aggression have empirically informed the development of an intervention to prevent aggression. The clinical perspective will be represented by discussing: a) the proper role of pharmacologic treatments as important, but adjuvant, interventions for BPS will be discussed; b) preliminary results from a randomized controlled trial providing therapeutic activities for persons with dementia and associated agitated behaviors using Montessori activities; c) results from a study of spaced retrieval techniques to prevent agitation in persons with dementia by providing skills that enhance feelings of autonomy and safety. Finally, implications of methodologic approaches to measuring outcomes in nonpharmacologic versus pharmacologic intervention studies will be examined.

### PREVENTING DEVELOPMENT OF AGGRESSION IN DEMENTIA: EPIDEMIOLOGICAL INTERVENTION DEVELOPMENT

M.E. Kunik, *1. VA Center of Excellence, Michael E. DeBakey VA Medical Ctr., Houston, Texas, 2. Baylor College of Medicine, Houston, Texas*

Preventing Development of Aggression in Dementia: Epidemiological Intervention Development Mark Kunik, mkunik@bcm.edu Historically, aggression has been pharmacologically treated without regard to specific causes. I will present results from our recent longitudinal study that identifies the incidence and important potential contributions to the development of aggression, including patient factors (pain and depression) and caregiver factors (burden and relationship quality) that predict development of aggression. Furthermore, the study finds that pharmacologic interventions are common; and non-pharmacologic interventions are nearly absent in routine clinical practice. The limitations of past pharmacologic interventions and the appropriate use of pharmacologic interventions as a co-treatment with non-pharmacologic interventions will be discussed. The implications of this study for the development of future interventions will be explored, and the pilot phase of a new treatment in development based on these study results will be presented.

### PRELIMINARY FINDINGS OF A CROSS-OVER TRIAL ON PERSONALISED, ONE-TO-ONE INTERACTION USING MONTESSORI-TYPE ACTIVITIES AS A TREATMENT OF AGITATION IN INDIVIDUALS WITH DEMENTIA

E. van der Ploeg, D. O'Connor, *Aged Mental Health Research Unit, Monash University, Cheltenham, Victoria, Australia*

Background This cross-over trial compares personalised one-to-one interaction to a relevant control condition in terms of reducing agitation and increasing positive engagement in persons with dementia. Methods 16 nursing home residents in Melbourne were exposed to two interventions; Montessori (attuned to their capacity and interests) and control (general conversation) activities. Number of agitated behaviours and type of engagement were noted before, during and after intervention time (30 min. per period). Results Outside intervention time residents on average displayed behaviours during 17 (out of 30) minutes. Both interventions were successful in reducing this agitation, with the Montessori intervention doing slightly better than the control intervention (respectively 9 min. vs. 11 min. with behaviours). Furthermore, residents were more constructively engaged, meaning that they participated more actively, during the Montessori intervention compared to the control intervention ($p<.01$). Discussion Whereas both non-pharmacological interventions reduce agitation significantly, the Montessori intervention elicits more active participation.

### TRANSITIONS IN COMPETENCE: A COMPARISON OF COGNITIVE STIMULATION AND SPACED RETRIEVAL IN A COMMUNITY-DWELLING SAMPLE WITH PROBABLE DEMENTIA

M. Luszcz, C. Materne, *Flinders University, Adelaide, South Australia, Australia*

Spaced retrieval (SR) has been shown to be successful in assisting people with moderate to severe dementia learn and remember personally relevant information. Previous research has predominantly focussed on intensive, sometimes daily, training schedules with residents in long-term care. An experiment was implemented with a mixed 'probable' dementia sample, drawn from the general community. SR was compared to a control condition of comparable length involving cognitively stimulating activities. SR training was designed to facilitate remembering of strategies to enhance day-to-day functioning by supporting remembering of important information. The protocol covered 9 weekly sessions, comprising 2 baseline, then 6 experimental, sessions. Baseline and the first follow-up session assessed memory self-efficacy in people with dementia (and their carers) and a spectrum of cognitive abilities. Initial SR results indicate that its benefits can be maintained over considerable intervals. Its implications for memory self-efficacy and generalization to other functions will also be presented.

### "TREATMENT" VERSUS "CARE": EFFECTS OF LABELS USED FOR INTERVENTIONS FOR PERSONS WITH DEMENTIA

J. Zeisel, *Hearthstone Alzheimer Care, Woburn, Massachusetts*

The "social facts" that sociologists study do not exist without formal organizations or informal interest groups "labeling" them and without the public embracing those labels. This presentation will explore how labeling in dementia has lead to popular acceptance of Alzheimer's as an "illness" rather than a "disability," medication as the only available "treatment," and nonpharmacologic approaches to reducing symptoms as "care" rather than "treatment." This latter label has lead to limited degrees of acceptance, funding and implementation. The implications of these labels will be explored with emphasis on the emergence and effects of the relatively recent "treatment" label attached to nonpharmacologic approaches, such as physical environment, the arts, and Montessori-based activity programming, as well as the "symptom" labels attached to the behaviors of "wandering," "sundowning," and "elopement." Analogies will be drawn with the historic labeling of "anxiety disorders" and "depression" as illnesses and the resulting treatments developed.

### COMPARING APPLES AND AARDVARKS: THE NEED TO DEVELOP COMMON METRICS WHEN COMPARING PHARMACOLIC AND NONPHARMACOLOGIC INTERVENTIONS FOR PERSONS WITH DEMENTIA

C. Camp, *Research & Development, Hearthstone Alzheimer Care, Woburn, Massachusetts*

A transition from an emphasis on Alzheimer's disease and associated disorders from a terminal illness to a chronic illness, and a corresponding transition of viewing both pharmacologic and nonpharmacologic interventions as treatments for symptoms associated with dementia, will be accelerated once common metrics are utilized in these two approaches. For a variety of reasons, there has been little effort to create common standards for determining the efficacy and effectiveness of these two approaches to symptom treatment. These include emphasis on diagnosis versus treatment, emphasis on recovery of function versus circumvention of deficits, regulatory emphases on acceptability of specific measures (e.g. FDA standards; use of MDS data), as well as historical and cultural trends within different research disciplines. Current NIH funding initiatives, as well as potentially useful opportunities for collaborative efforts involving utilization of both approaches to intervention for dementia, will be presented as possible means to alleviate this situation.

## SESSION 870 (POSTER)

## OLDER PARENTS/ADULT CHILDREN

### THE INFLUENCE OF RELIGIOSITY AND MARITAL STATUS ON SUPPORT GIVEN TO PARENTS

N.N. Flanigan, *Family and Child Sciences, Florida State University, Tallahassee, Florida*

Recent demographic trends such as high divorce rates and increased life expectancy will likely lead to an increase in the number of divorced and widowed older adults in the future. With the absence of a spouse, these adults are likely to rely on adult children for social support. In continuously married families, religious adult children exchange more support with parents. In divorced families, however, religiosity is negatively associated with exchanges of support. The link between religiosity and social support has not been compared in divorced and widowed families. The purpose of the present study was to determine the influence of religiosity and parent's marital status on the amount of social support that adult children give to widowed and divorced parents using data from 1193 parent-adult child dyads from Wave 2 of the National Survey of Families and Households. Measures of religiosity included adult child's religious preference, adult child's public religiosity, and congruence in public religiosity between adult children and their parents. Social support consisted of emotional (e.g., giving advice) and instrumental (e.g., help with shopping) support. Adult children with higher levels of public religiosity gave more support to parents than did those with lower levels of public religiosity. Religious preference and congruence in public religiosity did not affect support given to parents. Adult children with widowed parents gave more support to parents than did adult children with divorced parents. None of the interactions between religiosity and parent's marital status were significant.

### GIVING AND RECEIVING THE "RIGHT" HELP: EVALUATIONS OF AGING PARENTS AND THEIR MIDDLE-AGED CHILDREN ON HELP GIVEN AND RECEIVED

K. Kim[1], S.H. Zarit[1], K.S. Birditt[2], K. Fingerman[3], *1. Department of Human Development and Family Studies, Pennsylvania State University, University Park, Pennsylvania, 2. Institute for Social Research, University of Michigan, Ann Arbor, Michigan, 3. Department of Child Development and Family Studies, Purdue University, West Lafayette, Indiana*

Research on intergenerational support has mainly focused on the types and amount of support exchanged between generations. We know relatively little about how each generation feels about the support that they give and receive, and whether they view this support as adequate. This study examines how aging parents (G1) and their adult children (G2) evaluate the amount of support that they give and receive from each other, using 337 parent–child dyads. Each person independently reported the amount of help given and received from the other, and whether they perceived the amount of support to be more or less than they needed, or the right amount. Most participants reported the amount of support exchanged was the right amount or that it was less than they preferred. In addition, appraisals of the rewards and stresses of giving help and relationship quality are associated with perceptions of adequacy of support exchanged for both G1 and G2, even after controlling actual amount of support. These findings suggest a complexity in how support is perceived within a parent-child dyad. Although a majority of dyads agree about the appropriateness of the amount of support, a significant minority believe that they are giving and receiving too little. Not surprisingly, these differences are associated with general tensions in the relationship, as well as appraisals regarding the stresses and rewards of support exchange.

### DISCLOSURE OF WORRIES IN THE PARENT AND ADULT OFFSPRING DYAD

J. Lee[1], K.E. Cichy[2], E.S. Lefkowitz[1], S.H. Zarit[1], K. Fingerman[3], *1. Human Development and Family Studies, Penn State University, University Park, Pennsylvania, 2. Kent State University, Kent, Ohio, 3. Purdue University, West Lafayette, Indiana*

Studies have shown that adults and their parents commonly worry about each other. Yet, most research has relied on self-reports rather than behavioral observations. Little is known about worry disclosure between parents and adult offspring and its association with both parties' emotional states. The present study investigates: (1) generational differences in worry disclosure (2) gender differences in worry disclosure, and (3) associations between worry disclosure and (a) offspring's/parents' own emotional state and (b) the other party's (parents/offspring)'s emotional state. The present study investigates the following questions: (1) Which generation is more willing to disclose their worries about each other? (2) What are gender differences in disclosing worries? (3) What is the association between worry disclosure and (a) offspring's/parents' own emotional state and (b) the other party (parents/offspring)'s emotional state? Participants from the Adult Family Study included 158 offspring (51.9% female, aged 22 to 49), their mothers, and their fathers (N=474). Trained coders rated videotaped discussions between parents and offspring discussing what worries them about each other. Mothers and fathers disclosed their worries more than offspring did. As expected, mothers and daughters disclosed their worries more than fathers and adult sons. Using Actor Partner Interdependence Model (APIM) analysis, we also tested whether self disclosure of worries would be associated with one's emotional state and further with the other party's emotional state. For mothers, fathers, and offspring, how much they disclosed their own worries was associated with their own negative emotional states, such as worry and sadness. Adult offspring's worries, however, were also associated with mothers' emotional state. Findings underscore the importance of worry disclosure in research on emotional complexities in the parent-adult offspring relationship.

### FATHERS' TRADITIONAL ATTITUDES: THEIR ROLE IN THE FLOW OF SUPPORT FROM ADULT CHILDREN

M.W. Steinhour[1], J. Suitor[1], K. Pillemer[2], *1. Sociology, Purdue University, West Lafayette, Indiana, 2. Cornell University, Ithaca, New York*

The study of exchanges between parents and adult child has been a focus of research on intergenerational relations across the past half century. Studies have found substantial differences in the flow of support from children to mothers and fathers, but few differences in the predictors of these divergent patterns. We contend that there is one important predictor of support from children to fathers that has received no attention in the literature: fathers' traditionalism. In this paper, we explore the role fathers' traditionalism plays in their receipt of support from their children, using quantitative and qualitative data from older fathers collected as part of the National Survey of Families and Households and the Within-Family Differences Study. Specifically, we test the hypothesis that fathers who hold more traditional attitudes are less likely to receive both expressive and instrumental support from their adult children. Preliminary analyses suggest that the more traditional values fathers hold, particularly regarding gender, the less likely they are to receive support from their adult children. Examination of the qualitative data suggests that this pattern occurs because traditional fathers are less likely to solicit support or accept it when it is offered by their children.

### LONGITUDINAL ASSOCIATIONS AMONG PARENTAL EMOTIONAL SUPPORT, SLEEP, AND DEPRESSION OVER 3 DECADES

C. Poon, B.G. Knight, M. Silverstein, *University of Southern California, Los Angeles, California*

Background: Symptoms of sleep disturbances are reported by nearly a third of the adult population. Sleep problems can start in childhood and continue into later years. Early in life, adverse family experiences are associated with sleep problems. This study examined whether lower parental emotional support in late adolescence and young adulthood predicted sleep disturbances across a 35-year period, when depressive symptoms were taken into consideration. Method: Regression analysis was performed on 189 participants from the Longitudinal Study of Generations (LSOG) that included 8 waves of data from 1971 to 2005. Participants in the current analysis were under 21 (Mean = 17.66, SD = 1.31) and living with their parents in 1971. Of these, 128 remained in the study in 2005. Subjective evaluation of parent-child emotional closeness was reported in 1971. Non-somatic depressive symptoms and restless sleep were reported 7 times between 1985 and 2005. Results: Over 58% reported restless sleep 3 to 7 days a week in at least one wave of data collection. From 1985 to 2005, endorsement of restless sleep increased from 16% to 34%. Controlling for age, gender, and negative affect in 1971, lower parental emotional support significantly predicted more frequent endorsement of restless sleep between 1985 and 2005. The association remained significant after controlling for other non-somatic depressive symptoms in the same period. Conclusion: The influence of early parental emotional support on sleep and depressive symptoms persists into later adulthood.

### YOUNG ADULT OFFSPRING'S SUPPORT OF MIDDLE-AGED PARENTS

Y. Cheng[1], K.S. Birditt[2], S.H. Zarit[3], K. Fingerman[1], *1. Purdue University, West Lafayette, Indiana, 2. University of Michigan, Ann Arbor, Michigan, 3. Penn State University, University Park, Pennsylvania*

Research has documented the support middle-aged parents provide to grown children, but there has been less attention to support they receive from offspring. The first purpose of this study was to document how much support adults aged 18 to 30 provide their parents. The second purpose was to examine predictors of support to parents. Adult offspring from the Family Exchanges Study (269 women, 246 men; Mean age = 22.34, SD = 3.43) indicated how often they provide and receive support with each middle-aged parent (590 mothers, 571 fathers). They also responded to questions about relationship quality with parents, parental problems or crises in the past two years, and parental health status. On average, offspring reported providing support to parents once a month. Around 30% of offspring provided support several times a month or more frequently, while 38% helped only every few months or less often. Offspring's receipt of support was higher than their provision of support. Separate hierarchical regressions by parent gender examined whether support provided was explained by support received from parents, relationship quality, parental problems, or parental health controlling for offspring characteristics. Greater support received from parents, relationship quality, and parental problems predicted greater offspring support to parents. In sum, although young adult children provide less support than they receive, there was considerable variability in support from young adults to their parents. Young adult offspring who provide support to parents do so in the context of reciprocal support, affectual solidarity (or better relationship quality), and parental needs.

### PATTERNS OF FAMILY COMMUNICATION: A LOOK INSIDE AN ASSISTED LIVING FACILITY

C.L. Vair, S.H. Qualls, M.A. Doffing, M.D. Williams, *Psychology, University of Colorado, Colorado Springs, Colorado*

Families of older adults maintain regular and meaningful communication with elders, but placement in a facility (e.g., Assisted Living/AL) may disrupt the frequency or meaning of such ties. An intervention designed to foster communication between family members and AL residents offers an opportunity to examine patterns of communication in such families. Links between communication and well-being may be important as AL residents are known to be at risk of depression and loneliness. This study assesses the impact of the Family Connection Service (FCS), designed to facilitate communication between AL residents and families. The FCS allows residents to send text or photos from a one-touch digital mailbox with staff assistance to family emails. This poster describes the resident population, characteristics of one AL facility, and patterns of use of the FCS. A sample of 24 residents (67% of population) was recruited from a small, home-like Medicaid-funded facility (age range 48 to 94 years, M = 67.43, SD = 13.34). Initial resident usage was high for 40% of residents, with 60% rarely using the service. Interviews collected information about perceived frequency of communication, network membership and closeness, and resident well-being. The same measures were also completed by primary family members (reporting on the elder) electronically. The present study examines resident and network members' patterns of use, network size (range 2 to 13, M = 5.0, SD = 2.55), and measures of well-being. Findings are interpreted as demonstrating the acceptability and ease of use of the technology and value to residents and families.

### THE SUPPORTIVE ACTIONS FOR YOUNGER GENERATIONS AND PSYCHOLOGICAL WELL-BEING IN ELDERLY PEOPLE

M. Tabuchi[1,2], Y. Gondo[1], *1. Osaka University, Osaka, Japan, 2. Japan Society for the Promotion of Science, Tokyo, Japan*

In Japan, the role of elderly people in guiding and supporting next generations has been emphasized. The supportive actions for next generations are motivated by 'generativity', suggested by E.H. Erikson. These actions have an important effect on psychological well-being for not only young people but also elderly people. However, the conflicts between younger and older generations within the activities become a problem in some cases. In this study, we hypothesized that these actions would not lead to psychological well-being unless elderly people are received to be valued and get respect by the next generations. 150 Japanese elderly people responded to measures of generative concern, generative actions, perceived respect, and emotional psychological well-being. Structural equation modeling showed that generative actions had a direct impact on positive emotional well-being. In contrast, structural equation modeling showed that the effect of generative actions on negative emotional well-being was mediated by perceived respect. These results suggested that the supportive actions for next generations directly heightened positive emotional well-being. On the other hand, to reduce negative emotional well-being, elderly people have to receive the positive-feedback from the young people. In order to promote the supportive actions for next generations, positive-feedback system is needed for elderly people.

### A QUALITATIVE STUDY OF ELDERLY CHINESE IMMIGRANTS' MANAGEMENT OF CHRONIC ILLNESS, USE OF MEDICINES, AND HEALTHCARE DECISION-MAKING: THE ROLE OF ADULT CHILDREN

R.M. Mirza, *Pharmaceutical Sciences, University of Toronto, Toronto, Ontario, Canada*

Research on Chinese families documents the cultural importance of the family in providing health support and caregiving to elderly members. While research reveals that the onset of a parent's chronic illness sometimes requires adult children to play a greater role in managing a parent's health within the home and clinical setting, a dearth of empirical research exists regarding the ways in which caregivers and family members make healthcare decisions around the utilization of various health services and the use of various types of drugs. With an interest in collaboration between care providers (formal/ informal), the purpose of this study was to describe and develop an understanding of the experiences of adult Chinese-Canadians who help their elderly parent(s) manage a chronic illness. A qualitative research design was used. In-depth and follow-up interviews were conducted with participants (n=30), and case studies of familial healthcare decision-making (n=2). Health behavior was discussed within the context of the caregivers' relationships with family and community members, as well as with their commitment to/ rejection of particular views of health, various health care providers and practices. Treatment decisions were not always negotiated with the elderly parent or discussed with others, suggesting that caregivers are active in managing the health and health-care needs of their parents. This research was theorized around the notion of the caregiver as a decision-maker, and the findings challenge the view that caregivers and older family members always share the same health beliefs, treatment goals and orientations towards medicines as conceptualized in health research.

### FAMILIAL DISENFRANCHISEMENT: MIDDLE-AGED ADULTS LACK OF SUPPORT TO OFFSPRING

W. Chan[1], K.S. Birditt[2], S.H. Zarit[3], K. Fingerman[1], *1. Child Development & Family Studies, Purdue University, West Lafayette, Indiana, 2. University of Michigan, Ann Arbor, Michigan, 3. Pennsylvania State University, University Park, Pennsylvania*

Relationships between middle-aged adults and their offspring are often characterized by regular exchanges of support in areas such as emotional, practical, and financial support, socializing, talking about daily life, and giving advice. There has been scant attention, however, to situations where middle-aged adults provide little help to offspring. In this study, lack of support to offspring is defined as disenfranchisement, and is operationalized as providing offspring with help only yearly or even less. We examined predictors (parent characteristics, offspring characteristics) for disenfranchisement from parents to offspring. Adults aged 40 to 60 (N = 633) from The Family Exchanges Study reported how often they provided 6 kinds of support to each of their grown offspring (n =1384). The findings showed that more than 10% of participants (n = 73) reported disenfranchising 8.02% of grown children (n = 111). Logistic regression revealed that poorer relationship quality and low frequency of contact were associated with greater likelihood of offspring being disenfranchised. Additionally, disenfranchisement was associated with the perception that parents received low support from children. Other social structural variables were relatively unimportant in predicting disenfranchisement (e.g., parental marital status, ethnicity, and income). Social exchange theory helped to explain why parent disenfranchised offspring probably because they could minimize the cost by withdrawing their support on those offspring who did not provide help in return. Solidarity theoretical perspectives were adopted to illustrate that less positive relationship quality and low frequency of contact were associated with disenfranchisement.

## ORGANIZATIONAL LEADERS' PERCEPTIONS OF THE BENEFITS OF INTERGENERATIONAL COMMUNITY PROGRAMS

M.C. Janke, T. Young, *School of Aging Studies, University of South Florida, Tampa, Florida*

Participation in intergenerational programs has been associated with many positive benefits to older adults. Establishing intergenerational programs requires a collaborative effort in communities, yet little research has focused on the perceptions of intergenerational programs from the community service providers' point of view. This study examines the views of community organizations involved in The Linking Intergenerational Networks in Communities (LINC) Project (N = 32), a statewide, collaborative program offered in seven communities in South Carolina. Bivariate correlations and analyses of variance with post hoc tests were used to analyze the data. Our findings suggest that the type of organization involved in the project influenced perceptions of how well resources provided by LINC partners were efficiently used, with governmental agencies noting a significantly less effective use of resources than all other types of organizations. Reports of greater levels of overall satisfaction with the LINC project was associated with greater perceived benefits of the program to their constituents' needs, greater levels of collaboration between organizations in the community providing LINC, and a stronger belief that LINC enhanced the organizations' ability to serve their constituents. No significant differences were evident in outcomes based on whether the community organization was an aging service provider. Findings from this study are discussed in terms of implications for sustainability of intergenerational programs and suggestions enhancing aging service providers' experiences in intergenerational programs.

## MORTALITY RISK OVER MARITAL DISSOLUTION: THE ROLE OF RELATIONSHIP QUALITY

J. Bulanda, J. Brown, T. Yamashita, *Miami University, Oxford, OH*

Although a number of studies find that married adults are healthier and have longer lives than those who are unmarried or who experience marital dissolution (e.g., Dupre, Beck, & Meadows, 2009; Manzoli, Villari, Pirone, & Boccia, 2007), few examine the role of marital quality and almost none have utilized prospective, longitudinal data to assess how marital quality might moderate the relationship between union dissolution and mortality. Whereas the dissolution of a happy marriage may be associated with a higher risk of mortality, it is possible that the dissolution of an unhappy marriage may be better than remaining in the low-quality relationship. In this study, we extend the literature by examining not just mortality over the transition to divorce or widowhood, but rather if the risk is different based on the quality of the relationship. We also consider potential gender variation in the relationship; previous research indicates that the association between marital quality and mortality may be particularly strong for women (Rohrbaugh, Shoham, & Coyne, 2006), but that divorce may be particularly consequential for men's mortality (e.g., Brockmann & Klein, 2004; Kalediene, Petrauskiene, & Starkuviene, 2007). With data from over 7,000 married adults aged 50 and over from the 1992-2008 waves of the Health and Retirement Study (HRS), we compare the mortality outcomes of those who divorce or become widowed to those who remain married based on initial marital quality.

## FEMINIZATION OF POVERTY AND THE "INTERLOCKING SYSTEM OF OPPRESSION"—GENDERED POWER RELATIONSHIP AMONG CHINESE RURAL FAMILIES WITH MIGRATED CHILDREN

B. Luo, *Western Washington University, Bellingham, Washington*

Feminization is a world-wide phenomenon. This phenomenon may be more serious in rural China than other places in the world. Studies have consistent shown that compared to their urban elders and rural male elders, Chinese elderly women in rural areas are in the very bottom of the society and are the "poorest of the poor" due to China's ongoing history of patriarchy (including patrilineality, and patrilocality) compounding with current economic transformation. Using the theoretical model of Political Economy of Aging (PEA), this study delves into the phenomenon of feminization of poverty among rural elders with migrated adult children. A quantitative analysis was conducted based upon data from a rural household survey collected by gerontologists in Renming University in 2004 from three in-land migrant-exporting provinces. This study reveals that Chinese rural women's disadvantaged social, economic, and health conditions are a product of their longtime subordination due to the patriarchal family system, gendered social policies, the social transformation of rural-urban migration, and the state. These structural factors form an interlocking system of oppression in which gender, class, the state, and ideology interact with each other in shaping rural elderly women's lives.

## MOTHER-IN-LAW—DAUGHTER-IN-LAW RELATIONSHIP SATISFACTION: WHAT HELPS? WHAT HINDERS?

R.C. Jones, M. Turner, *Human Development and Family Sciences, University of Arkansas, Fayetteville, Arkansas*

The role of family kinkeeper is significantly impacted by the quality of the Mother-in-Law (MiL) and Daughter-in-Law (DiL) relationship. Understanding the factors contributing to the quality of this relationship is critical in order to assure intergenerational family solidarity. Research suggests that women in these two roles relate differently to their MiL/DiL than they do to any other family member (Turner, Young & Black, 2006). The current study compared factors contributing to DiL/MiL relationship satisfaction among 571 DiLs and 156 unrelated MiLs. The study assessed relationship styles derived from self-reported responses to a 35 item scale that factors into 5 subscales of the respondent's perception of how she relates to her DiL/MiL . Regression analysis indicated similarities and differences in the role of perceived styles of relating, age, length of marriage, level of education and satisfaction with their husband/son relationships predicted satisfaction with their DiL/MiL. For MiLs, the only style related to satisfaction with her DiL was Engager. The only other predictor for MiLs was satisfaction with her relationship with her son ($r^2$= .73, p=.000). For DiLs, two of the five scales, Utilitarian and Combative, were negatively related while the Engager subscale was positively related to DiLs' satisfaction with their MiL. Other factors predictive of satisfaction included DiL's age, length of marriage, and the DiLs' satisfaction with their relationships with their husbands ($r^2$=.78, p=.000). MiL and DiL styles of relating, factors related to relationship satisfaction, and the implications for strengthening intergenerational families will be discussed.

## A DECADE OF LOVE AND HATE: PATTERNS OF INTERGENERATIONAL AMBIVALENCE EXPERIENCED BY TWO COHORTS OF OLDER PARENTS AND ADULT CHILDREN

J. Lendon, M. Silverstein, *University of Southern California, Los Angeles, California*

The coexistence of affection and conflict or mixed feelings towards an older parent or adult child, known as intergenerational ambivalence, has sparked great interest in the study of aging families. Researchers have demonstrated that families experience more intimate than conflicted relationships, but it is also important to understand the contradictions within families. Studies have investigated many social, familial, and individual characteristics associated with ambivalence. However, we know little about how families experience ambivalence over the life course. This research used five waves of the Longitudinal Study of Generations from 1988 to 2000. Intergenerational ambivalence was assessed using an indirect measurement combining both positive (closeness and getting along) and negative (conflict and criticism) aspects of the relationships. We analyzed two sets of parent-child dyads (N=848) to compare patterns of ambivalence by familial perspective (parent versus child) and birth cohort using latent growth models. Average ambivalence scores indicated little to moderate levels of ambivalence. Fathers had slightly higher levels of ambivalence towards their child than mothers; children experienced greater ambivalence than parents. Cohort differences suggest greater ambivalence among baby-boomer parents and their children than older dyads. Significant decline in ambivalence for parents and children in both birth cohorts indicated the influence of later life on intergenerational relationships. The oldest cohort of parents experienced the lowest levels of ambivalence and the youngest cohort of children experienced the greatest levels of ambivalence. Significant individual variations in ambivalent feelings, with cohort differences, suggest different influences on ambivalence within aging families over the life course.

### EXCHANGES IN FINANCIAL AND NON-FINANCIAL SUPPORT BETWEEN ELDERLY PARENTS AND ADULT CHILDREN IN JAPAN

E. Kobayashi[1], T. Fukaya[1], H. Akiyama[2], M. Naoi[3], J. Liang[4], *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, 2. Institute of Gerontology, University of Tokyo, Tokyo, Japan, 3. Tokyo Gakugei University, Tokyo, Japan, 4. School of Public Health and Institute of Gerontology, University of Michigan, Ann Arbor, Michigan*

Japanese tradition dictates that the eldest son and his wife should live with his parents to provide old age support. Yet, today less than one half of older Japanese live with their children, reflecting a significant change in family relationships. This study examined (a) exchanges of instrumental support including financial and non-financial types between elderly Japanese parents and their adult children, and (b) key predictors of such exchanges. Data came from the National Survey of the Japanese Elderly conducted in 2006. Parents aged 77 or over responded to a face-to-face interview, whereas their children (aged 54 on average) were reached through a mailed questionnaire survey, resulting in 685 parent-child pairs. Relative to non-financial support (e.g., doing housework, ADL care), financial support is less prevalent. Only 20% of the children provided 60,000 Yen ($ 650) or more to their parents in the past 12 months, even less than those who received the same support from their parents. After controlling for parental needs, children's resources, and the travel distance from parents, logistic regression analyses showed little effect of being the eldest son and filial obligation on providing support to their parents. Reciprocity of different resources was observed. Namely children who received money from their parents were more likely to reciprocate with non-financial support, while those who received non-financial support from their parents were more likely to provide their parents with financial support. Emotional support from parents increased financial support only among daughters, suggesting gender differences in social exchanges.

### OLDER PARENTS ASSISTING THEIR ADULT CHILDREN IN CHILDCARE: DOES IT PAY OFF IN LATER LIFE?

T. Geurts[1], T. Van Tilburg[1], A. Poortman[2,3], *1. VU University, Amsterdam, Netherlands, 2. Utrecht University, Utrecht, Netherlands, 3. ICS, Utrecht, Netherlands*

The current study examines whether past grandparental childcare provision is related to present support from adult children. Based on social exchange theory and reciprocity, we expect that past childcare provision to children creates a debt that is repaid in the form of support from children later in life. Grandparental childcare provision was assessed in 1992. Support received from children was assessed at a follow-up observation in the Longitudinal Aging Study Amsterdam conducted between 1998 and 2009 (349 parents and 812 adult children). Our results indicate childcare provision to children increases likelihood of receiving support from children later in life. Other kinds of past instrumental support, such as help with daily chores, are not related to current support from children. The current study suggests that grandparental childcare provision can be conceived of as a relation-specific investment in children that leads to greater support from children in later life. The study supports the idea of long-term reciprocity in parent – child relationships.

## SESSION 875 (SYMPOSIUM)

### RECENT DIRECTIONS IN CRITICAL GERONTOLOGY

Chair: *T. Calasanti, Virginia Tech, Blacksburg, Virginia*
Discussant: *S. Katz, Trent University, Peterborough, Ontario, Canada*

Critical gerontology emerged in the 1980s, partly as a challenge to the dominant, individual-level approaches to aging, and typically focused on policies and practices that influence such issues as poverty and the creation of dependence among elders. Since then, critical approaches to aging have continued to evolve, in light of social changes including the demands of diverse populations, who challenge the emphasis on power relations based on class alone, and globalization. This symposium examines some of this recent work and its implications for future critical gerontological research. Leading off, Torres explains the importance of going beyond discussions of globalization and international migration to consider transnational communities, outlining a research agenda and giving examples of how an awareness of transnationalism can shape critical gerontology. Next, Scharf and his colleagues reflect on their use of participatory research in a project that promotes social engagement among disadvantaged elders. They discuss implications for social change and future research. The next two papers focus on the ways that discourses in relation to old age shape this time of life. Grenier explores the different discourses concerning health and illness and how these influences aging experiences, particularly in relation to the challenges that late life can pose. Calasanti, King, and Sorensen examine the ways that gendered, anti-aging discourse is reflected in the embodied beliefs and behaviors of middle-aged adults. Finally, Katz comments on the implications of these papers for late life experiences and for critical gerontology.

### TRANSNATIONALISM AS POINT OF DEPARTURE FOR THE EXPANSION OF THE SOCIAL GERONTOLOGICAL IMAGINATION

S. Torres, *NISAL, Linkoping University, Norrkoping, Sweden*

Although globalization and international migration are phenomena that have received some attention in critical gerontology, transnationalism has yet to engage the social gerontological community. This paper will define what transnationalism means, describe what characterizes transnational communities and present some of the research findings that transnational studies in other fields have brought to fore in attempt to extract the implications that this phenomena has for gerontology. The paper aims namely to delineate a research agenda for critical gerontology that is transnationalism-aware by discussing some of the concrete implications that this phenomenon has for the study of key gerontological issues, such as, for example, old age identity and intergenerational solidarity. Hence that the paper argues that transnationalism could expand the gerontological imagination even though transnational communities pose a challenge to gerontological policy and practice.

### FROM EXCLUSION TO INCLUSION? CRITICAL REFLECTIONS ON PARTICIPATORY ACTION RESEARCH WITH OLDER PEOPLE

T. Scharf[1], F. Ziegler[2], R. Beech[2], S. Maslin-Prothero[2], M. Murray[2], J. Bailey[2], A. Crummett[2], S. Middling[2], *1. National University Ireland Galway, Galway, Ireland, 2. Keele University, Keele, United Kingdom*

According to Phillipson and Walker (1987), critical gerontology reflects "a more value-committed approach to social gerontology – a commitment not just to understand the social construction of ageing but to change it" (p.12). Participatory designs that engage older people in key aspects of the research process are of increasing importance in providing evidence that can facilitate such change. Drawing on a conceptual framework that identifies older people's potential vulnerability to different dimensions of social exclusion, this paper reflects critically on the challenges associated with adopting a participatory action research design within the context the CALL-ME study – an empirical project supported by the UK research councils' New Dynamics of Ageing programme. CALL-ME aims to develop strategies for promoting social engagement among older people in disadvantaged communities of Manchester, England. The paper reviews the CALL-ME experience, developing implications for critical gerontology and suggesting ways in which researchers might develop future empirical studies.

### AGE RELATIONS IN LATE LIFE: RECONSIDERING DISCURSIVE DIFFERENCES

A.M. Grenier, *School of Social Work, McGill University, Montreal, Quebec, Canada*

Despite the prevalence of research on longevity, 'frailty' and risk in gerontological research, critical perspectives have yet to fully consider the implications of 'age-relations' in late life that are conceptualised primarily in relation to decline. Rooted in critical gerontology, this paper reflects on the polarisation of discourses of health and illness that appear within public policy, organisational practices, and lived experiences of older people. It will present evidence of the differential discourses used to shape expectations and behaviours at different points in 'old age' and the contradictions created through such practices. Discussion will turn to the conceptual challenges for research, policy and practice as it relates to late life (the so-called '4th age'). In doing so, it will renew the importance of considering 'late life relations' and the questions of age/decline-based targeting and what appears to be a growing separation from the issues and emotions of late life.

### THE ANTI-AGING INDUSTRY, GENDER, AND EMBODIED EXPERIENCES OF AGING

T. Calasanti, N. King, A. Sorensen, *Virginia Tech, Blacksburg, Virginia*

Scholarship on ageism makes clear that age relations exclude old people from full participation in society. Bodies serve as critical markers of age; thus people are motivated to present their bodies as "not old." The regulation of bodies and thus claims to full citizenship occurs in the context of an anti-aging industry that markets goods and services that promise to help people keep their bodies from aging. We examine pilot data gathered through in-depth interviews with 20 women and men aged 43-61 first, to determine the extent to which ageist discourse apparent in advertisements for the anti-aging industry are reflected in respondents' views of their aging bodies. Second, our exploration is sensitive to the gendered content of these messages, and we consider men's and women's anti-aging behaviors in light of these issues.

## SESSION 880 (SYMPOSIUM)

### SWEDISH RESEARCH ON LINKS BETWEEN HOUSING FOR AND CARE OF OLDER PEOPLE

Chair: *C. Nord, Linköping university, Norrköping, Sweden*
Discussant: *J. Hagberg, Linköping university, Norrköping, Sweden*

This Symposium Aims to Present Swedish Social Scientific Research About the Relationship Between Older People's Housing and Care. The Authors Are Members of the Nordic Research Network on Older People's Housing. The Symposium Reflects Various Dimensions of the Multi-faceted Concept of Care, Including Informal and Formal Care, and Self-care. The Authors Cover a Range of Housing Types That Include Senior Housing for Older People Living Independently, as Well as Residential Care Facilities for Those in Need of Extensive Support for Daily Living. The Encouragement of Independence, Involvement and Self-care is Stressed by All Authors, Even Regarding Older Individuals Who Might Be in Need of Substantial Formal Support. One Important Link Between Housing and Care That is Highlighted, is the Social and Gendered Aspects of Care and How Co-habitation and Social Interaction Between Older People Can Improve Self-care. Policy and Implementation Issues Are Raised by Some Presenters. The Respect for the Individual in Formal Care Situations is Explored Both in Terms of Social Policy and How the Physical Environment Can Contribute to Individual Care, for Example Through Design Guidelines for People with Dementia. Among Those Architectural Factors Which Influence the Well-being of the Frail and Old, Are Size and Organization of a Care Unit and Its Interior Design Qualities. The Authors Represent Various Methodological Fields. Qualitative as Well as Quantitative Research Are Presented.

### ARCHITECTURAL DESIGN FOR CARE OF THE MOST FRAIL AND OLD IN ASSISTED LIVING IN SWEDEN

C. Nord, *Linköping university, Norrköping, Sweden*

This is a Presentation of an 18-month Ethnographic Research Project in an Assisted Living Facility in Sweden. Results Showed That the Residents' Private Bedrooms Have Increased in Importance Since the Residents Stay 15 Hours or More in These Rooms Daily, Due to Frailty and Long-term Conditions. Swedish Laws State That Care of Older People Should Be Individualized. It is Desirable That Care is to Some Extent Located in the Persons' Private Bedrooms in Order to Adapt to the Frail Individual's Needs and Abilities. Assisted Living in Sweden is Legally on a Par with Ordinary Housing. From This Follows That Care Should Contribute to a Full Life of the Individual. Private Bedrooms in Assisted Living in Sweden Are Often Small and Dull. This Presentation Aims to Discuss What Architectural Qualities a Private Bedroom Should Preferably Have in Order to Make a Meaningful Day Possible for the Most Frail and Old People.

### THERE IS NO ESCAPE FROM GETTING OLD; ELDERS' EXPERIENCES OF ENVIRONMENTAL CHANGE IN RESIDENTIAL CARE

H. Falk, *University of Gothenburg, Health and Care Sciences, Gothenburg, Sweden*

The aim of this study was to achieve a comprehensive understanding of how environmental changes affect quality of life (QoL), wellbeing in frail elderly and how place attachment is created in residential care. Results show that interior design features alone have little importance to care climate, disruptions caused by refurbishments have negative effects on QoL, relocation has adverse effects for those able to self-report, preparatory programs are missing, and a sense of home is created through active strategies and psychosocial processes. There is a need for further research in order to avoid oversimplification in which a physical environment with an aesthetic appearance of a home becomes the general standard for good residential care. The quality of life of older persons may be improved by acknowledging the fundamental human need for a home, being a prerequisite for wise and supportive interventions aimed to improve the wellbeing and QoL in residential care.

### DISCOURSES OF USER AND USER INFLUENCE WITHIN THE ELDERLY CARE: A MATTER OF OPPORTUNITY-HORIZONS

K. Lundkvist Martinson, *Department of Social Studies, Institution of Social Work, Karlstad, Sweden*

The Concepts of User and User Influence are Highly Present in the Social Policy Debate on Elderly Care. They are Described as Vague, Problematic and Context-Dependant. Nevertheless, They are Rarely Problematized from the Elderly Care-Perspective. With this Paper, through a Discourse-Analytic Approach, I am Raising the Issue of Various Discourses of Elderly Users and Their Influence within the Elderly Care, as They Appear in Texts by Different Senders. Participants in this Activity will Hereafter be Able to Identify how the Elderly Users Can be Described and Who and What is Included and Excluded Respectively. I am Highlighting Tensions that Can be Found Within and Between these Discourses. Henceforth the Gathered Participants Will be Able to Discuss how this Can Contribute to the Views of Elderly Individuals on Their Possibilities and Limitations to Practice and to Have Influence on Their Everyday Life; Discourses as a Part of Elderly Individuals Perceived Opportunity-Horizons.

### ELDERLY RESIDENTS' NETWORKS AS A CARING RESOURCE: FOR WHOM AND WHEN?

C. Krekula, *Dept of Social Studies, Social care, Karlstad, Sweden*

Even though Research Emphasizes that Subjective Experiences of Old Age Depend upon the Resources elderly Individuals have access to, little Attention has been given to Residents' Networks and how these can Contribute to create Engendered Experiences of old Age. Departing from 12 qualitative Interviews with Women and Men between the ages of 72 and 89, all living in the Stockholm region of Sweden, I illustrate how Housing Arrangements can provide Resources such as Informal Care for the Elderly. I also reveal how Norms and Institutionalized Practices in these Housing Communities Contribute to Residents being able to take advantage of available Residential Resources to different extents. Thereby apparently homogeneous Housing Arrangements have different meanings for their Residents. In such way they also Create Engendered Experiences of old Age.

### NATIONAL GUIDELINES FOR CARING FOR PERSONS WITH DEMENTIA THE PHYSICAL AND PSYCHOSOCIAL ENVIRONMENT

H. Wijk, *Sahlgrenska Academy, Institution of Health and Care Sciences, Gothenburg, Sweden*

Dementia is an Incurable Disease but Evidence-Based Strategies Can Support Quality of Life and Well-Being. The National Guidelines Conforms Recommendations Considering Assessment and Treatment As Well As How to Arrange The Physical and Psychosocial Environment in Order to Support Orientation, Activities for Daily Living and Well-Being. An Important Principle is that The Care Should be Person Centred, Meaning that The Care and Environment Should Be Planned and Arranged For Out From an Individual Perspective. The Guidelines Concerning the Physical Environment Includes Recommendations Considering Architecture, Design and Size of The Dementia Care Unit, Aspects of Sound, Smell, Colour Scheme and Illumination as Well as The Outdoor Environment. Based on The National Guidelines, Quality Indicators are Stated in Order to Accomplish The Possibility to Assess and Follow The Quality of Dementia Care in The Communities. Keywords: Dementia, physical and psychosocial environment, national guidelines

## SESSION 885 (PAPER)

## TRANSITIONS TO RETIREMENT

### THE EFFECTS OF RETIREMENT TRANSITION ON DAILY WELL-BEING

J.D. Wong, D. Almeida, *Human Development and Family Studies, The Pennsylvania State University, University Park, Pennsylvania*

The transition into retirement represents unique challenges and opportunities that affect psychological well-being. The current study assesses the ways in which retirement transition predicts daily well-being across a 10-year span. Using data from the first and second waves of the National Survey of Midlife Development in the United States (MIDUS) and the National Study of Daily Experiences (NSDE), this study is comprised of 202 men and women between 55 and 74 years of age. Participants completed telephone interviews about daily time use, stressors, physical symptoms, and psychological distress over eight consecutive days. A series of hierarchical regression models were used to estimate the effects of retirement transitions, age, gender, marital status, education, and pension access as well as their interactions, on daily time use, psychological distress, and stressors. Controlling for household income and chronic health conditions, results showed that experiencing a retirement transition was associated with time spent giving emotional support and sleeping. These associations were moderated by gender, marital status, and education. Employment transitions also were associated with aspects of the daily stress processes. In the area of stressor severity, individuals who remained working reported greater stressor severity than those who transitioned into retirement. Findings from this study suggest the importance of examining retirement as a transition process in understanding how daily experiences are shaped.

### THE INFLUENCE OF WORK-RELATED FACTORS ON THE RETIREMENT DECISION MAKING PROCESS

H. Van Solinge*, Social Demography, NIDI, The Hague, Netherlands*

Decisions about retirement are not formed in a social vacuum but are shaped by the context in which individuals live. An aspect of this context that has received little attention are work-related factors and the workplace itself. This is remarkable, given that retirement is an occupational career transition. Retirement is one of several forms of organizational withdrawal that individuals may use to avoid dissatisfying work situations. In this investigation, we examined to what extent job characteristics (positive and negative working conditions; work-life balance arrangements) and organizational context (support for working longer by supervisor and organization) contribute to the propensity of employees aged 50 and over to continue working. Participants are 1.678 Dutch working adults (50-64 years) who are followed over a period of 6 years. Survival analysis suggests that remaining longer in the workforce is associated with positive job conditions and supervisor support for working longer. The availability of work-life balance arrangements (partial retirement) rather seems to speed-up retirement.This suggests that the effectiveness of flexible working arrangements as a tool in postponing the retirement age should be re-examined.

### ON BEING WORK-DISABLED: THE SOCIAL CONSTRUCTION OF HEALTH-MANDATED LABOR FORCE EXITS

D.F. Warner[1,2], J. Kelley-Moore[1], M. Stone[1], *1. Sociology, Case Western Reserve University, Cleveland, Ohio, 2. Bowling Green State University, Bowling Green, Ohio*

Health-mandated labor force exits are often defined by receipt of Social Security Disability Insurance (SSDI), but few studies have explored how the social constructions of age, disability, and retirement interact. For instance, early retirement, for those who can afford it, creates a socially-rewarded identity that allows mounting functional declines or debilitating chronic conditions to remain privatized and undocumented. For other workers, Social Security Retirement eligibility at age 62 allows one to receive a state-sponsored pension without needing to claim impairment, also rendering health-mandated exits invisible. Given racial/ethnic socioeconomic stratification in U.S. society, the prevalence of health-mandated exits is likely underestimated for all groups, particularly White adults. We examined how alternate definitions of work-disability affect our understanding of health-mandated labor force exits among 50-75 year olds using the 1992-2006 Health and Retirement Study. While 22% of older adults indicate that a health condition limits their ability to work (inability), only 10% identify as disabled and just 6% receive SSDI. Discrete-time hazard models in a competing-risks framework showed that while White older workers had higher risks of exiting via retirement than work-disability under all three alternate definitions, these differences were smaller when inability and largest when SSDI was the defining criterion. Income, wealth, and pension-eligibility significantly differentiated whether older workers exited via work-disability when defined in terms of identity or SSDI. Overall, our results support the conclusion that because work-disability is socially constructed, a considerable number of health-mandated exits among Whites are invisible, and largely reflective of their more privileged socioeconomic status.

### THE IMPACT OF WORK, HEALTH, AND FAMILY HISTORY ON MEN'S INTENDED AND ACTUAL RETIREMENT TIMING

M. Damman[1], K. Henkens[1,2], M. Kalmijn[2], *1. Netherlands Interdisciplinary Demographic Institute (NIDI), The Hague, Netherlands, 2. Tilburg University, Department of Sociology, Tilburg, Netherlands*

Previous studies on retirement timing have predominantly focused on proximal precursors of the retirement transition, such as the health and wealth situation of older workers. Preceding life histories have often been neglected or remained implicit. However, it is both scientifically and policy relevant to achieve a more explicit understanding of the relationships between these distal life experiences and retirement timing. This study aims to improve this understanding by (1) simultaneously studying the impact of earlier life experiences in different life spheres on (2) both retirement timing intentions and actual behavior, and thereby (3) theoretically and empirically distinguishing financial pathways from other pathways that link life histories with (intended) retirement timing. Panel data containing life history information, which were collected in 2001 and 2007 among older Dutch men (N=1229), were analyzed to reach this aim. In general, our results suggest that instability in work and family careers decreases the likelihood of (intended) early retirement. Mid-life experiences of dismissal and employer change, as well as having children relatively late and being recently divorced, decrease the intention to retire early. Severe health problems during midlife increase the intention to retire early. The work history relationships run mainly via the preretirement financial opportunity structure. For health and family history there are significant life course effects net of the financial situation. Only some of the life history predictors of retirement intentions are also related to actual retirement behavior, which might point to external forces inhibiting older workers to realize their preferred timing of retirement.

## SESSION 890 (PAPER)

## ADDRESSING FALLS AND MOBILITY IN THE 21ST CENTURY

### TASK-SPECIFIC TRAINING DECREASES LABORATORY-INDUCED FALLS BY OLDER WOMEN

M.D. Grabiner, M.L. Bareither, S. Gatts, J. Marone, K. Troy, *Kinesiology and Nutrition, University of Illinois at Chicago, Chicago, Illinois*

Task-specific training, also known as repetitive functional task practice and task-related training, and used in physical and occupational therapies, involves practicing context-specific motor skills and some form of performance-relevant feedback. We used a task-specific training protocol, simulating a forward trip, to improve the ability of older women to perform successful compensatory stepping responses. We hypothesized that older women who participated in the training protocol (n= 32) would have fewer falls following a laboratory-induced trip than a control group that received no training (n =31). The training protocol consisted of four non-consecutive sessions over a two week period. During each session the subjects, protected from a fall by a safety harness, stood on a custom motorized platform that delivered precise, displacement and velocity-driven postural disturbances (up to 50 per session) causing the subject to lose her balance and, consequently, to require a series of stepping responses to avoid falling. At least one week following the last training session, subjects participated in the induced-tripping protocol. The induced-trip caused 36% of untrained women to fall. In contrast, only one of the trained women (<5 percent) fell following the induced-trip. Consistent with our previous work, discriminant analysis correctly classified 84 percent of the trip-related falls and recoveries based on two trip-specific biomechanical variables, both of which were significantly improved by the training. The cost per "fall prevented was about $450. These results strongly suggest that the task-specific approach may be effective at reducing falls by older women at a reasonable cost of implementation.

### MIDLIFE WORK ABILITY AMONG WHITE- AND BLUE-COLLAR EMPLOYEES PREDICTS LATE-LIFE MOBILITY LIMITATION

M. von Bonsdorff[1], T. Rantanen[1], J. Seitsamo[2], C. Nygård[3], M. von Bonsdorff[2,1], J. Ilmarinen[2], *1. Gerontology Research Centre, University of Jyväskylä, Jyväskylä, Finland, 2. Finnish Institute of Occupational Health, Helsinki, Finland, 3. Tampere School of Public Health, University of Tampere, Tampere, Finland*

Objectives The aim of this study was to investigate whether midlife work ability predicted late-life mobility limitation among white-collar and blue-collar employees. Methods The 28-year prospective study on ageing municipal employees was conducted at the Finnish Institute of Occupational Health in 1981-2009. Baseline information was collected among 6257 municipal employees aged 44-58 years in 1981. Work ability was inquired as subjective assessment of present work ability and categorized into excellent, moderate and poor work ability. At the fifth data collection wave in 2009, 3092(73% of the survivors) answered the postal questionnaire. Perceived difficulty in advanced mobility was inquired from the 72-86-year-old participants with a question on the ability to walk 2 km (0=able to manage without difficulty to 4=unable to manage even with help), which was dichotomized into 0=no difficulties and 1= at least some difficulties. Analyses were performed with logistic regression models and adjusted for age, gender and number of physician-diagnosed chronic diseases. Results Among white-collar employees, the adjusted odds ratio (OR) for mobility limitations 28 years later was 1.81 (95% confidence interval 1.45-2.25) for those with moderate and 2.40 (1.74-3.31) for those with poor workability compared to those with excellent work ability in midlife (reference). Similarly, among blue-collar employees the odds ratios for mobility limitation were 2.11 (1.52-2.94), 2.27 (1.75-2.93) and 3.92 (2.79-5.51) for those with excellent, moderate, and poor work ability in midlife, respectively. Conclusions This prospective study showed that work ability in midlife predicted mobility limitations 28-years later. The risks were similar for both occupational groups.

### ADDED BENEFITS OF USING VIRTUAL REALITY FOR IMPROVING GAIT AND REDUCING FALL RISK IN PARKINSON'S DISEASE

J.M. Hausdorff[1,2,3], A. Mirelman[1,2], I. Maidan[2], N. Giladi[2,3], *1. Harvard Medical School, Boston, Massachusetts, 2. Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, 3. Tel Aviv University, Tel Aviv, Israel*

Background: Traditional gait training approaches are limited in their ability to challenge patients and reduce fall risk. Virtual reality (VR) delivers an exciting and enjoyable training modaility that involves both motor and cognitive challenges and also allows for real-time modification of task difficulty based on performance. In this study, we evaluated, for the first time, the feasibility of using VR to improve usual-walking, dual-tasking and obstacle negotiation in patents with Parkinson's disease (PD). Methods: 20 patients with PD (age: 66.8±6.21 yrs; disease duration 9.6±5.4 yrs; Hoehn&Yahr stage 2) completed 18 training sessions (3 times/week x 6 weeks) that included walking on a treadmill with virtual obstacles. Outcome measures included gait, balance, and PD symptoms. Results: Usual-walking gait speed improved from 1.12±0.23 m/s to 1.26±0.29 m/s (p=0.004), and the distance walked in

6 minutes increased by 57.7 meters (p=0.03). Stride length and gait variability obstacle negotiation over-ground improved and the dual-task decrement was reduced (p<0.05). Parkinsonian symptoms (p=0.02) and performance-based measures of dynamic stability (p=0.02) also improved. Training effects were maintained at 1 month post-training. Conclusions: To our knowledge, this is the first time that VR has been used for gait training in PD. The results support the idea that treadmill training with VR positively impacts on many fall risk factors including usual-walking, obstacle negotiation and dual-tasking, likely via "motor learning." Since PD mirrors many of the effects of "exacerbated" aging, the present findings suggest that VR might be a novel way of reducing fall risk among older adults.

### EFFECTS OF MULTIMEDIA FALL PREVENTION TRAINING ON PERSONS WITH PARKINSON'S DISEASE

V. Panzer[1,3], J. Burleson[2], F. Into[1,3], *1. Univ of Connecticut Health Center, Neurology, Farmington, Connecticut, 2. Univ of Connecticut Health Center, Community Medicine & Health Care, Farmington, Connecticut, 3. Brookside Research & Development, North Salem, New York*

Purpose: To examine the influence of multimedia (MM) fall prevention training on recognition of personal predisposing factors or fall 'threats' in seniors with Parkinson's disease (PD) or other impairments. Methods: In a randomized, double-blind trial, 279 Seniors (60-96 years, mean=79, SD=7 had fall history and lifestyle interviews, were trained to keep daily logs and telephoned weekly by independent research associates. Participants completed Usual or MM (Usual +1-2 MM sessions) treatment. Sessions included interactively viewing vignettes emphasizing key fall threats which were 'Customized' to the individual or 'Standardized'. One month later, ten novel scenes (not part of MM training) were viewed by all participants and the number of fall threats recognized were recorded by research associates who did not conduct MM training. Univariate, sequential multiple linear regression analysis with Gender, Age, Parkinson's disease/Impairment (whether or not assistance with ADLs was required), MM Training and Customization included all main and 2-way interaction effects. Results: Main effects of participant Gender (p=.001, females Adjusted Mean(SD) M=30.5(9), n=190; males M=27.8(9), n=89) and Age (p=.028, older participants recognized fewer fall threats) influenced fall threat recognition. Participants with PD recognized still fewer fall threats than those without PD who needed assistance with ADLs (p=.053, PD-M=25.9(8), n=22; Non-PD Impaired-M=31.2(10), n=33). MM training was highly influential (p=.001, M=30.2(8), n=169; Usual training M=26.9(10), n=110). Customization of the content further increased MM effectiveness (p< .001, Customized M=34.1(8), n=73; Standardized M=26.6(7), n=96). Conclusion: Multimedia fall prevention training is less successful in increasing fall threat recognition in participants with PD. Since the effects of customization are pronounced, creating MM content appropriate to the unique characteristics of PD may improve results.

## SESSION 895 (SYMPOSIUM)

### DEMENTIA AND END-OF-LIFE CARE: FORGET TO FORGIVE AND SIMPLY FORGETTING

Chair: *G. Gambassi, Geriatrics, Università Cattolica, Rome, Italy, Alpert's Medical School Brown University, Providence, Rhode Island*
Discussant: *V. Mor, Alpert's Medical School Brown University, Providence, Rhode Island*

Dementia is now a leading cause of death in the United States, with projection estimates of 16 million individuals having dementia by 2050. However, dementia is underrecognized as a terminal illness and the lack of information characterizing the final stage of dementia may impede the quality of care provided to these patients. The final disease trajectory of dementia is characterized by severe functional impairment, eating problems, malnutrition, and recurrent infections. More than one-third of nursing home residents with advanced dementia have a feeding tube inserted despite conclusive evidence that does not improve survival, prevent aspiration pneumonia, heal or prevent decubitus ulcers, or improve other clinical outcomes. Recurrent infections and febrile episodes typically occur during advanced dementia. Therefore, nursing home residents with advanced dementia are at high risk for exposure to antimicrobial agents. However, it is unclear whether treatment of infections confers any life-prolonging or symptomatic benefit in this population. At the same time, administration of antimicrobials to frail older patients who are near the end of life is also a potentially burdensome intervention. Pain is highly prevalent in these patients but it is dramatically underassessed and undertreated. Palliative care-a form of treatment that strives to match care to patient goals, relieve pain, and improve quality of life for people with chronic or life-threatening illnesses-should be the standard of practice for all elderly dementia patients in nursing homes, regardless of prognosis. The symposium will illustrate that dementia is indeed a terminal illness and will further knowledge about the clinical complications characterizing its final stage. Furthermore, the symposium will highlight the unnecessary suffering imposed on these patients by prescribing and procedures with no prognostic impact, and will emphasize the potential benefit of palliative care

### NATURAL HISTORY OF ADVANCED DEMENTIA

G. Gambassi, *Geriatrics, Università Cattolica, Rome, Italy*

Dementia is a leading cause of death in the United States but is underrecognized as a terminal illness. Advanced dementia is associated with a life expectancy similar to that for more commonly recognized end-of-life conditions, such as metastatic breast cancer and stage IV congestive heart failure. Nonetheless, the clinical course of advanced dementia has not been described in a rigorous, prospective manner. The incidence of clinical complications, the extent of physical suffering, and the use of burdensome interventions are not well understood. Prospective studies now show that pneumonia, febrile episodes, and eating problems are frequent complications in patients with advanced dementia, and these complications are associated with high 6-month mortality rates. Distressing symptoms and burdensome interventions are also common among such patients. The lack of information characterizing the final stage of dementia may impede the quality of care provided to these patients. A better understanding of the clinical trajectory of end-stage dementia is a critical step toward improving the care of patients with this condition.

### EATING PROBLEMS AND TUBE FEEDING IN ADVANCED DEMENTIA

J.M. Teno, *Alpert's Medical School Brown University, Providence, Rhode Island*

Over 5 million Americans have dementia, of whom 70% will receive terminal care in nursing homes (NH). Eating problems commonly present during the final stage of dementia. Nationwide, 33% of NH residents with advanced dementia are tube fed, despite no demonstrable benefits in this population in terms of key outcomes such as prolonged survival or improved nutritional markers. Marked variation in tube feeding exists across states and among NHs within states. Large database studies identified factors associated with tube feeding in advanced cognitive impairment, including individual patient characteristics, NH features, state laws, Medicaid payment, and health care transitions. The reasons for these associations are not easily explained using secondary analyses of large databases. In this session, it will be reviewed the existing data regarding decision making and outcomes of feeding tube insertion. Additionally, it will be proposed a new order Comfort Feeding Only to facilitate physician-caregiver communication regarding feeding tube insertion.

### FEBRILE EPISODES AND ANTIBIOTICS IN ADVANCED DEMENTIA

S. Mitchell, *Harvard Medical School, Boston, Massachusetts*

Infectious episodes are hallmarks of advanced dementia. However, it remains unclear as to whether antimicrobial treatment confers any life-prolonging or symptomatic benefit in these terminally ill patients, for whom the goal of care is often palliation. The widespread antimicrobial use in advanced dementia raises serious concerns not only from the perspective of individual benefits and burdens near the end-of-life, but also from a public health standpoint with respect to the emergence and spread of antimicrobial- resistant bacteria. The objectives of this presentation are discuss the following with respect to the infectious episodes in advanced dementia: 1. Epidemiology and natural history, 2. Evidence regarding the treatment options for infectious episodes, and 3. An approach to decision-making.

### THE ROLE OF PALLIATIVE CARE FOR PEOPLE WITH DEMENTIA

S.R. Morrison, *Mount Sinai School of Medicine, New York, New York*

The management of dementia is becoming a major national and international public health concern because increased longevity places more individuals at risk of developing this disease. Furthermore, a systematic review of trials investigating the efficacy of palliative care for older people with dementia, concluded that there is now unequivocal evidence of the efficacy for a palliative model of care in dementia. This presentation will reinforce the importance of providing appropriate palliative care to individuals suffering from end-stage dementia and some of the barriers to extending such specialist palliative care provision. These include concerns that such an expansion might lead to skills and funding shortages and, in turn, compromise the ability of existing specialist palliative-care teams to provide care to cancer patients. Clinicians and patient groups caring for patients with advanced dementia must work together with specialist palliative-care services and health commissioners to develop, fund and evaluate appropriate cost-effective services which meet patient and family needs. If this is achieved these improvements have the potential to increase quality of life, reduce hospital length of stay and the use of non-beneficial resources. Last and most importantly, terminally ill patients suffering from dementia will therefore not be subjected to protracted, potentially uncomfortable and undignified deaths.

## SESSION 900 (SYMPOSIUM)

### FELLOWSHIP SYMPOSIUM: AN INTERDISCIPLINARY PERSPECTIVE OF HEALTHY AGING

Chair: *W. Ladiges, Comparative Medicine, University of Washington, Seattle, Washington*

Co-Chair: *D.L. Morris, Case Western Reserve University, Cleveland, Ohio*

If we assume aging is a medically controllable health risk, then healthy aging is a collective right as well as an individual responsibility. But before we can successfully implement healthy aging programs and individual efforts, we must have a better understanding of what constitutes healthy aging. There is currently no well accepted definition of healthy aging, nor has its biological basis been fully determined. This symposium is designed to define healthy aging based on biological, clinical, behavioral and social, and policy and practice perspectives. Four speakers, each a Fellow representing either Biological Sciences, Health Sciences, Behavioral and Social Sciences, or Social Research, Policy and Practice Sections, will provide a detailed description of healthy aging and how their working definition broadly integrates with the other section disciplines. The objective of this interdisciplinary approach will be to provide for the audience an opportunity to see the relationship and integration of healthy aging based on focused perspectives. A second objective will be to obtain a broad overlapping definition of healthy aging that should be useful in efforts to establish healthy aging guidelines for increased support for biological and clinical research, geriatric care, and social and public health programs. It is concluded that the future of successful aging will depend on the combined efforts of basic and translational research, clinical care and social support.

### A BIOLOGIST'S VIEW OF HEALTHY AGING

G. Martin, *Comparative Medicine, University of Washington, Seattle, Washington*

Nature (genes that are inherited), Nurture (environmental factors) and Chance (stochastic events) all interact to modulate the degrees to which a life course can be characterized as "healthy aging". This presentation will consider examples of impacts of both "good" and "bad" varieties of genes, environment and luck in order to better understand why some of us do well, while others do poorly. Our goal as biologists is to understand underlying mechanisms in sufficient detail so that rational interventions can be used to move us in the direction of healthy aging – the maintenance of relatively robust structure and function throughout most of the life course – up to that period which might be characterized as "terminal decline". A deeper understanding of biological, medical, psychological, sociological, economic, political and ethical aspects of variations in the durations and patterns of such terminal declines will require much more research. That research needs to be interdisciplinary.

### BUILDING RESILIENCE FOR SUCCESSFUL AGING

B. Resnick, *University of Maryland, Baltimore, Maryland*

Resilience is a dynamic process of adaptation to adversity and is conceptualized to reflect an effective response to some type of adversity or challenge, whether this be physical, psychological, economic, political, environmental, or social. Resilience is thus central to understanding successful aging because adversity is inevitable at points throughout the lifespan and certainly as we age. It is those who are resilient who have the motivation, determination and impetus to engage in regular exercise activities, volunteer in the community, to optimize function and recovery following acute events such as a stroke or hip fracture, regardless of underlying physical challenges, pain, or fear, and to age successfully. Resilience can be strengthened, improved and called upon to establish, maintain or regain a state of physical, psychological or emotional equilibrium over time. This session will review interventions to stimulate and build resilience in older adults as a way to facilitate successful aging.

### EXPANDING HORIZONS FOR HEALTHY AGING: DIVERSE VIEWPOINTS FOR A DIVERSE SOCIETY

E. Kahana, *Sociology, Case Western Reserve, Cleveland, Ohio*

This paper offers perspectives on theoretical and empirical approaches to understanding healthy aging and, more broadly speaking, aging well in our rapidly changing society. Older adults are increasingly likely to pursue initiatives in health maintenance, and continue productive roles as they craft a meaningful old age that affords them a high quality of life. Research by members of the BSS section highlights both growing diversity among older adults, and alternative pathways elders find to achieve their goals of aging well. This paper explores a range of orientations to define and operationalize healthy aging, focusing on subjective evaluations of health, as well as more objective externally defined assessments. Mixed-methods designs will be discussed, as they can inform alternative conceptualizations of healthy aging. Emerging pathways to promote health in late life will be considered, ranging from technology use in searching for health information, to participation in health education and health promotion programs.

### PROMOTING HEALTHY AGING: A POLICY AND PRACTICE PERSPECTIVE

T. Wetle, *Public Health, Brown University, Providence, Rhode Island*

Objective: Participants will identify missed opportunities to promote healthy aging across the life span. They will recognize how Gerontological research provides the evidence-base for effective interventions to promote healthy behaviors and improved health services. The World Health Organization defines health as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity". Thus, efforts to promote healthy aging must address not only treatment or prevention of diseases common in older populations, but also social and emotional well-being. Contributions are made from research focused on the basic biology of aging and related disease interactions, on clinical geriatrics to prevent and treat disease and functional limitations, and on behavioral and social sciences to place the elder in context. Using a public health perspective, this presentation identifies missed opportunities for improving the health of aging populations, drawing upon evidence-based strategies. These include interventions to promote healthier behaviors among older persons, to improve clinical practice regarding screening and treatment, and community-based interventions that build healthier communities. Conclusions: Multi-disciplinary research provides the evidence-base for improving population health and optimizing the well-being of older persons.

## SESSION 905 (POSTER)

## FRAILTY AND END OF LIFE: FAMILY, FAITH, FRIENDSHIP AND FEELINGS

### THE LOSS FEELINGS OF THE ELDERS AFTER HIP FRACTURE IN TAIWAN

Y. Huang[2,1], S. Tang[3], L. Chen[4,1], H. Cheng[1], Y.L. Shyu[2], *1. Nursing, Chang-Gung institute of Technology, Tauyuan, Taiwan, 2. Chang Gung University, Taoyuan, Taiwan, 3. Ming Chuan University, Taoyuan, Taiwan, 4. YuanPei University, ShinChu, Taiwan*

Clinical and scientific significance. Hip fracture is one of the events that impaired functional activities of elders. Most elders recovered incompletely even after a long time. Previous researches showed some elders experienced depression after hip fracture. The other studies demonstrated the elders felt lost because of separation or disabilities. However, little studies explored the loss feelings of the elders after hip fracture, and the impact of hip fracture on their lives and health. Research Purposes. The research purpose is to explore (1) the loss feelings of the elders after hip fracture, and (2) the impact of hip fracture on their lives and health. Data and Methods. This is a qualitative follow-up study. Patients above 60 year- old with hip fracture were recruited at Chang Gung Medical Center in northern Taiwan. Interviews were conducted in 1st, 2nd, 3rd, 6th and 12th month after discharge by home visiting. Transcribed information was analyzed using content analysis technique described by Miles and Huberman. Results. Four males and seven females completed the interviews during Jun 2007 to Dec 2009. Two categories of loss feelings were identified, (1) Decrease vitality— incomplete recovery, and (2) Hard to control the future— troubles or diseases followed continuously, such as cancer, Parkinsonism and others. The elders regarded the hip fracture as an adversity which their health began to decline. Conclusion. All cases expressed loss feelings. Two of them felt depressive, the others felt lost sometimes, but could manage it. The feelings were different by their health status and functional abilities.

### FROM THE NHHS AND NHHCS DATASETS: TRENDS IN HOSPICE-PALLIATIVE CARE SERVICES IN LTC FROM 2004 TO 2007

C.A. Yeager[1], L. Hyer[2], R.C. Intrieri[3], *1. Institute for Mental Health Policy, Research, and Treatment, Essex County Hospital Center, Cedar Grove, New Jersey, 2. Georgia Neurosurgical Institute, Mercer University Medical School, Macon, Georgia, 3. Western Illinois University, Macomb, Illinois*

Objective: There is now good evidence that hospice and palliative care services (H/PC) provide better, more cost effective care than conventional care for individuals at end of life. However, H/PC has not been routinely assessed in long term care. We report on findings from two national CDC datasets, the 2004 National Nursing Home Survey (NHHS) and 2007 National Home Health and Hospice Care Survey (NHHCS) regarding H/PC services offered to nursing home residents at end-of-life. Method: Samples were derived from the 2004 NHHS and 2007 NHHCS, consisting of all individuals receiving H/PC in a skilled nursing facility at time of interview. The 2004 NNHS was conducted between August and December, 2004, and the NHHCS between August 2007 and November 2008. Systematic sampling of agencies produced over 1,000 nursing homes in 2004 and over 1,000 home health and hospice agencies in 2007, generating an unweighted sample of 306 and 1008 H/PC residents respectively. We compared services offered during the two time periods, including: symptom and pain management, grief counseling, ethics/legal counseling, etc. Results: Services utilized by hospice patients and families increased somewhat between 2004 and 2007. Specifically, social services, such as grief/spiritual/ethics counseling, were offered with greater frequency in 2007. Findings regarding mental healthcare utilization and psychiatric problems were less optimistic, however. 2007 data show that depression as a diagnosis, for example, was inconsistent with staff-rated depressive symptoms. Moreover, very few patients designated as depressed or anxious received mental health services. Implications of such findings in H/PC shall be elaborated.

### CHARACTERISTICS OF HOME CARE SUPPORTING CLINICS FOR HOME DEATH OF THE ELDERLY IN THE JAPANESE METROPOLITAN REGION

H. Mikami, A. Akiyama, *Division of Health Sciences, Osaka University Graduate School of Medicine, Suita City, Japan*

Aim: With the advent of an extremely aged society in Japan we are facing increasing challenges of the end-of-life home care for the frail elderly. The aim of this study was to examine the requisites of home care system for home death of the elderly in the metropolitan region. Methods: This study was an anonymous mailed survey of 998 home care supporting clinics in the 23 wards of Tokyo, Japan. We constructed a questionnaire including clinic's characteristics, collaboration with hospitals, other clinics, home visit nursing stations and care managers, the number of people who died at home, and home care self-assessments. Results: Seventy eight percent of home care supporting clinics provided home care and home death to ≥1 patients per year (mean±SD: 7.5±16.6, range: 0-161). The number of home death patients was 20.9±33.4 per year in the clinics managed by ≥ 5 physicians (15.0%), which was 5 times as many as that of the clinics managed by < 5 physicians. In stepwise multiple linear regression analysis of factors influencing home death as a dependent variable, significant influential factors were: the number of physicians in the clinic (β: 0.38), the number of nurses in the clinic (β: 0.27), and collaboration with hospitals (β: 0.24). Conclusions: These results suggest that sufficient manpower for home care along with close collaboration with hospitals is needed for the realization of home death of the elderly in such a highly populated area as the Tokyo metropolitan region.

## PREFERENCES FOR CARE NEAR THE END OF LIFE AMONG ELDERS WITH CHRONIC DISEASES IN KOREA

S. Yu[1], Y. Chae[2], *1. Dept.of Nursing, Sangji University, Wonju-si, Gangwon-do, Republic of Korea, 2. Gangwon University, Chuncheon-si, Gangwon-do, Republic of Korea*

Introduction : The purpose of this study was to define preferences for advance directives (ADs) and care near the end-of-life (PCEOL) of elders with chronic diseases in Korea. Methods and materials: One hundred five participants from a convenience sampling were recruited from two hospitals in Korea. All participants completed questionnaires including Korean version(Kim & Lee, 2009) of PCEOL-K which was originally developed by Gauthier and Froman (2001). PCEOL-K consisted of 5 dimensions; autonomous physiological decision making, decision making by health care professional, spirituality, family, and affective communication. Results: Nearly all participants (98.1%) indicated that they were not aware of ADs and means to make their end-of-life wishes. They preferred that their wife (28.6%) or their son/daughter (45.7%) make healthcare decisions when they could no longer make their wishes. Relatively positive preference for care near the end of life toward pain control, family, decision making by health care professional, spirituality and negative preference toward autonomous physiological decision making were explored. Conclusion: If we advertise properly, it is highly likely that a large number of elders with chronic disease would make their wills easily by ADs. So Nurses should engage their patients in an ongoing communication about the end-of-life and consider family, pain control, spirituality as important factors at the end-of-life care by culturally tailoring to Korean.

## FEASIBILITY OF USING A VALUES INVENTORY AS A DISCUSSION AID ABOUT END-OF-LIFE CARE

S. Menon[1], L.B. McCullough[3,1], D. Espadas[1], U. Braun[1,2,3], *1. Houston Center for Quality of Care and Utilization Studies, V A Medical Center, Houston, Houston, Texas, 2. Baylor College of Medicine, Department of Medicine, Section of Geriatrics, Houston, Texas, 3. Baylor College of Medicine, Center for Ethics and Health Policy, Houston, Texas*

Feasibility of Using a Values Inventory as a Discussion Aid about End-of-Life Care Background: Knowledge of seriously ill patients' values and preferences is critical for providing excellent end-of-life care and facilitating care transitions. Conversations to elicit such preferences can be difficult and time-consuming. A Values Inventory (VI) can be useful to facilitate conversations about end-of-life care. Objectives: To test the feasibility of using a VI as a discussion aid in primary care clinical setting. To evaluate the satisfaction of patients with using a VI. Methods: Twenty Physicians from an urban VA Medical Center and six seriously ill patients of each physician were recruited (total n=140). Patients were randomized into a usual care and a VI group. Patients in the VI group completed the one page instrument in the waiting room and were instructed to discuss it during the physician-patient encounter. All encounters were audio-taped, transcribed and qualitatively analyzed. Results: Despite a specific and targeted intervention, only eight of 60 patients asked the physician to go over the VI leading to a discussion about end-of-life care. No discussions about end-of-life care happened in the usual care group. Nonetheless, patients were very satisfied with the VI and interested to discuss it with family members. Discussion: Primary care clinic visits rather than acute hospitalizations for chronic serious illnesses have been promoted as ideal setting for discussing end-of-life care. However, the low effectiveness of our intervention questions how feasible such discussions are during short primary care visits that were dominated by medication refills.

## PATIENT AND FAMILY PERCEPTIONS OF PALLIATIVE CARE CONSULT SERVICE CONFERENCES

P. Housen[1], S. Enguidanos[2], N. Jauregui[3], B. Mejia[3], J. Miller[3], M. Penido[3], *1. Partners in Care Foundation, San Fernando, California, 2. University of Southern California, Los Angeles, California, 3. Huntington Hospital, Pasadena, California*

Purpose: Significant evidence attests to the ability of inpatient Palliative Care Consult Service (PCCS) programs to improve patient-level outcomes, decrease acute care service use, and produce cost savings. A key element of PCCS is the patient/family conference, which is commonly used to provide information and develop goals of care jointly. The purpose of this study was to elicit care recipients' perspectives of patient/family conferences, which few studies have examined. Design & Methods: Qualitative interviews were conducted with 26 patients/family members who participated in PCCS conferences at an urban medical center. Participants completed a brief demographic survey and their perceptions were elicited using a semi-structured interview protocol. Interviews were audiotaped/transcribed verbatim, and statements were coded using a modified set of conceptual themes pertaining to elements of ideal palliative care (Philip & Komesaroff, 2006). Results: Patients/families characterized the relationships and the quality of communication with the PCCS, citing the team's relaxed and approachable communication style. Additionally, respondents identified receipt of comprehensive information about the patient's overall health condition as useful in goal setting and care decision-making. Improved symptom control and pain management were also key factors associated with patient/family conferences. Obstacles to the receipt of ideal palliative care included timeliness of the conference, inconsistent or incomplete information, and patient/family resistance. Implications: Findings from this study provide PCCS teams and hospitals with information about the perceived value of patient/family conferences, and identify areas for improvement.

## A PREDICTION MODEL FOR CARE BURDEN AND LIFE SATISFACTION OF THE DEMENTIA ELDERS' CAREGIVERS

Y. Lee, J. Lim, *Nursing Department, Inha University, Incheon, Republic of Korea*

Purpose: This study is to investigate factors that may impact on caregivers' life satisfaction and care burden, and help to reduce stress of care givers by nursing intervention on such factors. Methods: Study was designed to construct a model that predicts the care burden and life satisfaction of the dementia elders' caregivers. The study was conducted using a convenient sampling method from 8 Dementia Day Care Center at Incheon, Korea. One hundred eighty family caregivers answered the questionnaires. Data were analyzed by descriptive statistics and correlational analysis using SAS 10.0 program. The Linear Structural Modeling (LISREL) 8.13 program was used to find the best fit model. Results: The overall fit of the hypothetical model to the data was good, with statistically significant expected chi-square value (GFI=.94, RMR=.17, RMSEA=.13, NNFI=.99, NFI=.99). Compared to the hypothetical model, the revised model has become parsimonious and had a better fit to the data, in terms of expected chi-square value(GFI=.98, RMR=.12, RMSEA=.06, NNFI=1.00, NFI=1.00). The predictable variables of dementia caregivers' life satisfaction were depression, fatigue, perceived health status and care burden. These variables explained 65% of life satisfaction of the dementia elders' caregiver. The predictable variables of dementia caregivers' burden were depression, fatigue and functional status of demented elders. These variables explained 69% of caregivers' burden in this model. Conclusion: From the above results, it is necessary to develop the intervention program that may help care givers depression and fatigue, which will reduce care burden and promoting the life satisfaction of care givers.

### CAREGIVER DISTRESS PRIOR TO A FAMILY MEMBER'S DEMENTIA DIAGNOSIS: GENDER AND GENERATIONAL CONTRASTS

N.J. Stewart[1], D.G. Morgan[2], D.A. Forbes[3], C. Karunanayake[2], J. Wickenhauser[2], *1. College of Nursing, University of Saskatchewan, Saskatoon, Saskatchewan, Canada, 2. Canadian Centre for Health and Safety in Agriculture, University of Saskatchewan, Saskatoon, Saskatchewan, Canada, 3. Faculty of Health Sciences, University of Western Ontario, London, Ontario, Canada*

The day of dementia diagnosis is an emotional transition for family members. In this study, we compared family caregivers according to gender (male vs. female) and relationship (spouse vs. child) on measures of burden, severity of distress and health (mental and physical) at the initial in-person visit to a rural and remote memory clinic for diagnosis of early dementia. Ethics approval was obtained and family members signed an informed consent form before completing three questionnaires about their caregiving experiences and health. Of 175 caregivers relevant to this analysis, there were 66 wives, 49 daughters, 42 husbands, and 18 sons. Caregiver data were collected prior to the end-of-day meeting when team members provided feedback to the patient and family about the diagnosis. Analysis of Variance was used in a factorial design to compare these four caregiver groups as two factors (gender x relationship) on each of four indicators of distress and health. We found that women (wives + daughters) reported significantly more caregiver burden ($p < .0001$), greater severity of distress ($p < .0001$), and lower mental health ($p < .01$) than men (husbands + sons). In the relationship analysis, spouses (wives + husbands) reported greater severity of distress ($p < .05$) and lower physical health ($p < .01$) than children (daughters + sons). There were no interaction effects between gender and relationship. These results suggest that differing needs for support exist based on type of caregiver. Differences in physical health between spouses and children may reflect age-related deterioration for spouses.

### FORMAL/INFORMAL CAREGIVER INTERACTIONS IN THREE DISTINCT MODELS OF CARE

B. Baney[1], J. Penrod[1], J.E. Muscat[2], *1. The School of Nursing, The Pennsylvania State University, University Park, Pennsylvania, 2. Penn State Milton S. Hershey Medical Center, Hershey, Pennsylvania*

Both health care providers and family caregivers are integral to the care of patients suffering life-limiting illnesses. Family (informal) caregivers often provide the majority of home care, interfacing with health care providers (formal caregivers) only during brief office visits across the trajectory of illness. Such clinic interactions are opportunities for health care providers to support their informal partners in care. This study investigated interactions between the formal/informal caregivers and the key characteristics of three distinct care delivery models: interdisciplinary team, cooperative network, and dominant provider. Data were collected in a larger ethnographic study in which the models of care delivery were identified. Observation of clinic visits (n=450) produced textual field notes that were re-coded for quantitative analysis in this study. Multivariate analysis tested hypotheses based on the ethnographic findings: interactions between the informal and formal caregivers were associated with characteristics of model of care delivery, the informal caregiver, and the care recipient. These findings support theoretical assertions being formulated in the ethnography and, ultimately, contribute to the integration of supportive care for informal caregivers in varied delivery settings.

### COMPARISON OF PHYSICAL, PSYCHOSOCIAL, AND ENVIRONMENTAL CHARACTERISTICS AMONG NOT-FRAIL, PRE-FRAIL, AND FRAIL ELDERLY IN KOREA

J. Song[1], G.S. Hong[2], M. Park[3], I. Shin[4], *1. College of Nursing, Korea University, Seoul, Republic of Korea, 2. Department of Nursing, Colleg of Medicine, Hanyang University, Seoul, Republic of Korea, 3. College of Nursing, Keimyung University, Daegu, Republic of Korea, 4. Department of Medical Statistics, School of Medicine, Catholic University of Daegu, Daegu, Republic of Korea*

Recently studies have suggested that frailty is a multidimensional concept resulting from physical, psychological, social, and environmental factors. However, little data is available to support such a multidimensional perspective of frailty. In the present study, a sample of 286 community dwelling Korean elderly with age of over 60 (Male 43.7%, Female 56.3%) was used to investigate differences of physical, psychosocial, and environmental characteristics among not-frail (NF) (n=62), pre-frail (PF) (n=116), and frail (F) (n=108) groups. For each group, subjects were conveniently selected from the random sample used for the 2008 national study of Korean elderly based on the five markers of frailty suggested by Fried et al. (2001). Three groups were compared according to: pulse rate, blood pressure, waist-hip ratio (WHR), Body Mass Index (BMI), maximal expiratory flow, balance, number of prescribed medication, experience of medication side effect, number of physical symptoms; ego-integrity, family function; and home environment. One way ANOVA and Chi-square tests were mainly used for data analyses. Significant ($p<.05$) group differences were found for most variables except for blood pressure, WHR, BMI, and home environment. Results of this study may be useful not only for understanding various aspects of frail Korean elderly, but also developing customized health promotion programs for pre-frail or frail elderly. However, interpretation and generalization of the findings should be tentative. Further studies with a larger sample and longitudinal study design would be of great value.

### FRAILTY IN MEXICAN AMERICANS: WHERE THEY LIVE MAKES A DIFFERENCE

S.E. Espinoza[1,3], H.P. Hazuda[2,3], *1. Medicine, Division of Geriatrics and Gerontology, University of Texas Health Science Center at San Antonio, San Antonio, Texas, 2. University of Texas Health Science Center at San Antonio - Medicine, Division of Clinical Epidemiology, San Antonio, Texas, 3. South Texas Veterans Health Care System, San Antonio, Texas*

Background: Previous studies have shown that frailty prevalence is higher in ethnic minority groups who often have lower socioeconomic status compared with European Americans (EAs). This study examined whether neighborhood differences are related to frailty prevalence among older (65+ years) Mexican Americans (MAs). Methods: Subjects were 371 MA participants in the San Antonio Longitudinal Study of Aging baseline examination sampled from three socio-culturally distinct neighborhoods: barrio (lower-income, predominantly MA), transitional (middle-income, equal proportion MAs and EAs), and suburban (upper-income, predominantly EA). Frailty was classified using standardized criteria, and odds of frailty in the transitional and barrio neighborhoods relative to the suburbs was estimated using multiple logistic regression with age, sex, education and household income as covariates. Results: Prevalence rates varied significantly across neighborhoods (barrio: 15.6%, transitional: 9.4%, suburban: 3.5%, $p=0.01$). Residence in the barrio neighborhood was associated with a five-fold increase in the odds of frailty after adjustment for age, sex, and education (OR=5.2, 95%CI: 1.5-17.4). After additional adjustment for household income, however, the odds ratio was attenuated and only marginally significant (OR=3.2, 95%CI: 0.9-11.6). Residence in the transitional neighborhood was associated with a three-fold increase in the odds of frailty but was not statistically significant (OR=2.9, 95%CI: 0.7-11.4). Conclusion: Living in the barrio was associated with five-times greater likelihood of frailty among older MAs. Income was a major contributor to this association but did not fully explain the neighborhood difference. Future studies are needed to identify additional aspects of barrio neighborhood contexts that contribute to increased risk of frailty.

### PLASMA HAPTOGLOBIN IN PRE-FRAIL OLDER ADULTS: A PILOT STUDY

S.E. Espinoza[1,2], A. Pierce[1,2], D. Halade[1,2], A. Richardson[1,2], *1. University of Texas Health Science Center at San Antonio - Barshop Institute for Longevity and Aging Studies, San Antonio, Texas, 2. South Texas Veterans Health Care System, San Antonio, Texas*

Background: Frailty is a common geriatric syndrome, which has been associated with hematologic system changes. A proteomics-based screen of plasma glycoproteins using 2-dimensional gel electrophoresis has shown that haptoglobin spot-intensity is elevated in pre-frail versus non-frail older adults. The purpose of this study was to determine if plasma levels, using enzyme-linked immunosorbent assay (ELISA), are elevated in pre-frailty. Methods: Frailty was assessed using established criteria in 33 community-dwelling older adults. Pre-frailty was defined as the presence of one or two of weak grip, slow walk, weight loss, exhaustion, or physical inactivity; non-frailty was defined as none of these. Plasma haptoglobin levels were determined with ELISA using a commercially-available kit (Genway). Difference in haptoglobin concentration between pre-frail and non-frail was determined with two-sample t-test. Results: 17 (51.5%) of the subjects were pre-frail, 21 (63.6%) were female, and the mean age was 79.5 ±5.6. Overall, haptoglobin concentration was 1.24 ±0.4 mg/mL. Haptoglobin concentrations were elevated in pre-frail (1.4 ±0.5) compared to non-frail older adults (1.1 ±0.4); however, this difference did not reach significance (p=.086). There was no significant association between haptoglobin and age or sex. Conclusion: Haptoglobin concentration was found to be higher in pre-frail compared to non-frail older adults. While these results are limited due to small sample size, these findings suggest that pre-frail older adults show differences in haptoglobin concentration, prior to the onset of overt clinically-recognizable frailty. Future studies should include larger examinations of this association and consider the potential usefulness of haptoglobin as a biomarker for frailty.

### HOW DOES DECREASED SKELETAL MUSCLE MASS AND HIGH BODY MASS INDEX INFLUENCE PHYSICAL FUNCTIONING AND IMPAIRMENTS?

M.E. Canon, E. Crimmins, *University of Southern California, Los Angeles, California*

Research has suggested that body composition changes with age, leading to a decrease in muscle mass, known as sarcopenia, and an increase in fat mass. In this study we examined the effect of both sarcopenia and obesity on physical functioning. We used the National Health and Nutrition Examination Survey (NHANES 2003-2004) to examine 1,694 male and female participants over the age of sixty. Physical functioning, body mass index (BMI), height, and appendicular skeletal muscle (ASM) were evaluated in each subject and ASM, BMI and Physical functioning were all measured as continuous variables. Physical functioning was assessed using eight self-report measures (e.g. standing up from an armless chair). ASM was measured by dual-energy x-ray absorptiometry (DXA) and the value was determined by summing the lean tissue mass from regions of the arms and legs, then dividing it by the square of the subject's height. Ordinary least squares regression was implemented controlling for age, gender, race/ethnicity, income and several conditions that respondents identified as related to reduced physical functioning (e.g. back problems, diabetes, and fractures). We found that ASM alone was not significant (p =0.16) in predicting physical functioning. However, when ASM was assessed with BMI, both variables were significantly related to differences in physical functioning ($\beta$ASM = -0.637; p<0.000, $\beta$BMI = 0.236; p<0.000). This finding underscores the importance of examining ASM and BMI together and suggests that, lower muscle mass and higher BMI increase the prevalence of physical disability among older adults.

### PREDICTORS OF REMAINING NON-FRAIL: A POSITIVE APPROACH TO AGING AMONG MEXICAN AMERICANS

R.A. Samper-Ternent, K. Gerst, L.A. Ray, A. Michaels-Obregon, *Sealy Center on Aging, University of Texas Medical Branch, Galveston, Texas*

Introduction: Despite the large percentage of older adults with debilitating medical conditions and disability, there is a considerable number that live independent and healthy lives. Little research has examined adults that remain non-frail and none have studied it in older minority populations. Data: Two waves of data from the Hispanic Established Population for the Epidemiologic Study of the Elderly (H-EPESE) Wave 2 (1994-5) and data from the Frailty sub-analysis 10 years later (2004-5) were used for this study. Participants: The baseline sample consisted of 660 community dwelling Mexican Americans aged 67 and older, designated non-frail according to the frailty index by Fried et. al (2001). Logistic regression was used to predict remaining non-frail 10 years later. Results: Of the 660 non-frail elders at baseline, 45% died over the next 10 years. However, 23% remained non-frail. Logistic regression results found that age was a significant predictor, younger individuals had higher odds of remaining non-frail (OR =.90). Also, females had significantly higher odds of remaining non-frail, compared to their male counterparts (OR=1.85). Diabetes was the only comorbidity significantly associated with the outcome at follow-up; persons without diabetes at baseline were more likely to remain non-frail (OR=.52). Conclusion: These findings suggest that additional factors are protecting older Mexican Americans from becoming frail. Diabetes education and close clinical control must be encouraged in this population group. Future studies need to analyze factors like social support and psychological well-being as protective factors against frailty in older Mexican Americans.

### SOCIAL SUPPORT PERCEPTIONS AND NEEDS OF OLDER LESBIANS

M. Gabrielson, M.J. Dyck, *Illinois State University, Normal, Illinois*

Previous research suggests that older lesbians have often not maintained close biologic family ties and mistrust and/or avoid conventional services for support for fears of discrimination. Lesbian elders have often focused their social lives around an informal support network of friends they deem critical to their health and well being. The importance of these networks is likely to increase as lesbians age (at a time when the networks may be more difficult to keep intact). In cases where their informal social networks are not intact, older lesbians may experience a disparity in support for their needs resulting potentially, in negative health outcomes. A consensus is growing regarding the health effects of social support on older adults. Findings from an ongoing internet based survey study of older lesbians in the Midwest exploring the participants' perceptions of their social networks, the social support given by them (and from whom) as well as factors associated with their perceptions are discussed. Results of the survey as well as practice implications that may be drawn from the analysis and future research directions will be presented. There has been an inadequate amount of research devoted to factors that impact the health of older lesbians. We must better understand their support needs to provide optimal care for and prevent health disparities among this vulnerable population.

### ADVANCE DIRECTIVES IN THE CONTEXT OF COGNITIVE IMPAIRMENT

L. Garand[1], J.H. Lingler[1], M. Dew[2], *1. Health & Community Systems, The University of Pittsburgh School of Nursing, Pittsburgh, Pennsylvania, 2. The University of Pittsburgh School of Medicine & Health Center, Pittsburgh, Pennsylvania*

Objective: Persons with mild cognitive impairment (MCI) and Alzheimer's disease (AD) are at heightened risk for future decisional incapacity. We sought to characterize advance care planning (ACP) rates over time in individuals who had no advance directives (living will or durable power of attorney) in place when they initially presented for a cognitive evaluation. Design: Secondary analysis of prospectively recorded clinical data. Setting: Alzheimer's Disease Research Center memory disorders clinic. Participants: Persons (N=127) with a diagnosis of MCI or early AD (n = 72) or moderate to severe AD (n = 55) and no advance directives upon initial presentation for a cognitive evaluation. Measurements: Extraction of responses to items pertaining to advance care planning assessed during annual semi-structured interviews. Results: By 5 years of follow-up, 39% of the sample had initiated ACP, with little difference by baseline diagnosis. Younger subjects (under 65 years old) were significantly more likely to initiate advance directives (43%) than were older subjects (37%). This age effect was more pronounced in men than women as well as in married subjects, those with a family history of dementia, no depressive disorder, and subjects with moderate to severe AD (versus those with MCI or early AD) at baseline. Conclusion: Only a minority of subjects initiated ACPs. The findings suggest the need for interventions aimed at enhancing ACP completion rates, particularly among older adults with MCI and early AD since these individuals may have a timed-limited opportunity to plan for future medical, financial, and other major life decisions.

### AN EXAMINATION OF COMMUNITY AND FAITH-BASED RESOURCES FOR PERSONS WITH DEMENTIA AND THEIR CAREGIVERS

R.S. Conner, L.S. Nemeth, E. Amella, *CON, MUSC, Charleston, South Carolina*

Background: The gap in the literature regarding the needs of persons with dementia (PWD) and their caregivers related to caregiver stress from the perspective of individuals that provide community and faith-based support services provided the basis for this study. Purpose: This explanatory study identified the perceptions of 13 key informants from the community regarding the challenges associated with caring for PWD, the unmet needs of PWD and their caregivers, and finally, the role that the faith community could play in providing assistance to PWD and their caregivers. Methods: Using a qualitative descriptive design approach with semi-structured interviews, content analysis was conducted to identify the key informants' perceptions. A snowball sampling method was used to obtain a variety of community and faith-based representatives. Findings: The results validated prior work showing that the principle challenge associated with caring for PWD is caregiver stress. Improved program, facility, and health care provider support was identified as the primary need for PWD and their caregivers. Religious support at the church/synagogue, as well as in the home was identified to be the key role for faith communities in providing assistance to PWD and their caregivers. Conclusion: Comprehensive education for PWD and their caregivers about dementia provided by health care professionals who are adequately trained about the disease, prognosis, and community resources in tandem with religious support in the home and on-site by the faith communities could alleviate some components of caregiver stress.

## SESSION 910 (PAPER)

## ISSUES IN LONG TERM CARE

### TRANSITIONS EXPERIENCED BY THE OLDEST OLD LIVING IN ENGLISH CARE HOMES

I.A. Eyers[1], E. Cope[1], R. Luff[2], S. Arber[2], *1. Faculty of Health and Medical Sciences, University of Surrey, Guildford, United Kingdom, 2. Department of Sociology, University of Surrey, Guildford, United Kingdom*

The transition into care home life for oldest old people is influenced by their need for support or assistance with everyday activities ranging from washing and dressing to experiencing a walk in the park. Despite the rhetoric surrounding personalised care the constraints of institutional living cause reality to present a diverging picture. Based on a mixed methods study undertaken in 10 English care homes this paper provides an insight into the everyday experiences of care home residents and staff. Data were collected from 183 male and female residents aged 65 – 100 (mean age 85-90). For two weeks diaries denoting residents' daily activities were maintained and interviews were conducted with staff (n=50). The findings exemplify how the 24 hour rhythm of the day reflects a medical model curtailing personalised care. Consequently failing to acknowledge individuality and that a care home is where older people live day in day out for months if not years. Choice of when and how someone is washed and dressed is restricted by staffing levels and the reality of a walk in the park is restricted by the availability of staff and the outcome of a health and safety policy guided risk assessment. There is a need to transform the delivery of care to ensure it addresses the actual needs and expectations of the older people experiencing care home life. This research is supported by the New Dynamics of Ageing initiative, a multidisciplinary research programme funded by AHRC, BBSRC, EPSRC, ESRC and MRC (RES-339-25-0009)

### POLICIES AND PRACTICES RELATED TO ORAL NUTRITION SUPPLEMENT USE IN LONG-TERM CARE FACILITIES

S. Johnson, *Faculty of Kinesiology and Health Studies, University of Regina, Regina, Saskatchewan, Canada*

For frail older adults living in LTC facilities, oral nutrition supplements (ONS) are associated with increased body weight. These supplements are typically ready-made, liquid, and energy-dense, containing both macro- and micronutrients; they can benefit those experiencing unintentional weight loss for which weight gain is a goal. The present study examined the policies and practices related to oral nutrition supplement (ONS) use in elderly individuals living in long-term care (LTC) facilities. Thirteen LTC facilities within a large regional health authority participated, and 17 people responsible for prescribing ONS in their facilities were interviewed, using a key informant telephone survey. In addition, the study included a retrospective chart audit. Oral nutrition supplements were primarily prescribed by nursing staff (59%), followed by physicians, registered dietitians, or other staff; ONS use was prescribed for decreased intake, unintentional weight loss, or wound healing. Various ONS products (e.g., Ensure, Boost, or Resource 2.0) were prescribed. Only 18% of respondents reported using alternative food options first to supplement nutritional intake, before introducing ONS. In terms of follow-up and evaluation, the measures of improvement included weight gain, wound healing, or improved well-being; reasons for discontinuation included weight gain, increased intake, or death. Within LTC settings, the prescription and monitoring of ONS vary considerably. Evidence-based guidelines for the prescription and monitoring of ONS and for the use of a food-first strategy should be developed, implemented, and evaluated to optimize the nutritional health of the elderly in LTC facilities.

### ORAL HEALTH IN THE NURSING HOME: A COMPARISON BETWEEN MDS 2.0 DATA AND ACTUAL OBSERVATIONS

R. Jablonski[1], C. Munro[2], M. Grap[2], M.B. Ligon[3], *1. School of Nursing, Penn State, University Park, Pennsylvania, 2. Virginai Commonwealth University, Richmond, Virginia, 3. York College, York, Pennsylvania*

The Minimum Data Set (MDS, 2.0) is an important tool that provides information about the required care and health of nursing home (NH) residents. As part of a larger study designed to measure the effect of an intervention on denture and dental plaque in NH residents, we compared data reported in the MDS, Section L (Oral/Dental Status) to actual observations. The study was conducted in two NHs that differed by geography, ownership, and reimbursement patterns. Thirty-four NH residents with dementia were enrolled: 69% female, 31% African-American, and 69% white. There were no differences between facilities in residents' functional status, level of cognitive impairment, or baseline plaque scores. The residents' mouths were examined and the number of decayed, missing, and filled teeth were recorded. Plaque scores were also obtained using the University of Mississippi Oral Hygiene Index, with 0 indicating the absence of plaque and 10 indicating that plaque covered all surfaces of all teeth or dentures. According to the MDS data, none of the residents were listed as having debris in their mouths; we determined that the 31 subjects with some natural dentition had mean plaque scores of 9.55 (SD=0.89). Per the MDS, 11% had loose, broken, or carious teeth; we found that 43% had decayed teeth. MDS 3.0 is replacing MDS 2.0 and contains significant revisions to Section L. While this is a step in the right direction, the MDS 3.0 data remains contingent upon actual assessments and the strength of these assessments by nurses in long-term care.

## SESSION 915 (PAPER)

## OUTCOMES OF CARDIOVASCULAR DISEASE IN OLDER ADULTS

### THE IMPACT OF COMORBIDITY ON MORTALITY AMONG OLDER PERSONS WITH ADVANCED HEART FAILURE

S. Ahluwalia[1], C.P. Gross[2], S. Chaudhry[2], T.R. Fried[2], *1. Veterans Administration Greater Los Angeles, Los Angeles, California, 2. Yale University, New Haven, Connecticut*

Background: Little is known about the contribution of comorbidity to mortality in advanced heart failure (AHF). Identifying the impact of comorbidity on mortality in AHF can help to identify patients at risk for increased mortality and facilitate informed decision-making. We sought to identify the mortality risk associated with a broad range of comorbid conditions among older adults with AHF Methods: Longitudinal cohort study of 18,322 Medicare beneficiaries with HF. AHF beneficiaries were matched to beneficiaries with non-advanced heart failure (NHF) by age and gender, and followed from match date (T0) to death/censorship (T1). We used Cox proportional hazards regression models to estimate the effect of comorbidity on mortality. Results: Comorbidity was significantly associated with increased risk of mortality, even among AHF beneficiaries. For example, AHF beneficiaries with 3-4 comorbidities were 22% [HR: 1.22; 95% CI: 1.13, 1.31] more likely to die than those with <2 comorbidities, while NHF beneficiaries with 3-4 comorbidities were 49% [HR: 1.49; 95% CI: 1.39, 1.59] more likely to die than their counterparts with <2 comorbidities. Most comorbidities were individually associated with increased mortality risk in both groups. For example, dementia was associated with a 1.50 [95% CI: 1.43, 1.60] hazard of dying among AHF beneficiaries, and a 2.19 [95% CI: 2.05, 2.34] hazard of dying among NHF beneficiaries. Conclusions: Comorbidity continues to confer a significant mortality risk among older adults with AHF. Interventions aimed at reducing mortality risk for this population may need to simultaneously target co-existing conditions as well as heart failure to be effective. Comorbidity information can be used to identify a population who may benefit from palliative services and to facilitate informed treatment decision-making at the end of life.

### EFFECTIVENESS OF ACEI/ARBS IN VA NURSING HOME RESIDENTS WITH HEART FAILURE

E. Hutt, M. Ho, L. Pointer, E. Shahan, *Medicine, Denver VAMC, University of Colorado Denver, Denver, Colorado*

Objective: Clinical trials have demonstrated the efficacy of angiotensin converting enzyme inhibitors and angiotensin receptor blockers (ACEI/ARB) for heart failure (HF). Whether the same benefits accrue for HF patients in nursing homes, given their comorbidity burden, is unknown. We therefore assessed the association between ACEI/ARB prescription and subsequent mortality and rehospitalization in a national sample of VA nursing home (community living center – CLC) residents with HF. Methods: A national cohort of 13,147 veterans with diagnosed HF residing in CLCs during 2003-4 was identified from the VA's Medical SAS and Minimum Data Set files. Demographics, baseline function, biochemical markers, comorbidity, facility characteristics, and medications for subjects who experienced a subsequent hospitalization or death were compared to those who did not. Predictive logistic regression models for mortality and rehospitalization were developed. Propensity to be prescribed ACEI/ARB was derived using nonparsimonious logistic regression. Time to event was analyzed for the propensity-matched subjects (survival cohort n=7182; rehospitalization cohort n=7508) adjusting for covariates. Results: Annual mortality was 27.6% and rehospitalization 30%. Fifty percent had any advance directive; 58% had been prescribed ACEI/ARB. After adjustment, subjects who were prescribed ACEI/ARB had a 0.677 odds of dying (95% CI: 0.614 - 0.746). Time to death and rehospitalization were significantly longer ($p<.001$) in propensity-matched subjects taking ACEI/ARB. Conclusions: Prescribing an ACEI/ARB to VA CLC subjects with HF was associated with better survival and prolonged time to rehospitalization. Improving rates of ACEI/ARB prescription in this population may reduce morbidity and mortality.

### GERIATRIC FEATURES OF OLDER PATIENTS WITH ACUTE MYOCARDIAL INFARCTION: THE AMI-FLORENCE 2 REGISTRY

M. Di Bari[1], D. Balzi[2], A. Barchielli[2], F. Orso[1], S. Fracchia[1], C. Baroncini[1], G. Gensini[1], N. Marchionni[1], *1. Critical Care Medicine and Surgery, University of Florence, Florence, Italy, 2. Unit of Epidemiology, Local Health Unit, Florence, Italy*

Purpose. To investigate whether geriatric characteristics influence the choice of immediate treatment and long-term outcome of older patients with ST- and non-ST-elevation myocardial infarction (STEMI, NSTEMI). Methods. From April 2008 through April 2009, all acute coronary syndromes admitted to hospitals in the Florence area (Italy) entered the AMI-Florence 2 Registry. In randomly selected patients aged 65+ years, a succinct multidimensional geriatric assessment questionnaire investigated geriatric characteristics, such as living in a long-term care facility, functional limitations, memory disorders, sight or hearing impairments, previous hospitalizations, use of home care services, and use of 5+ drugs prior to admission. A summation score (SS) was calculated. Study outcomes were application of percutaneous coronary intervention (PCI) and 6-month mortality. Results. In 372 randomly selected participants (162 STEMI, 210 NSTEMI), application of PCI was systematically less frequent in the presence than in the absence of each mentioned geriatric feature. PCI was applied in 43% and 56% of participants with an SS above and below 4, respectively (OR 0.48, 95% CI 0.25-0.94, p=0.032, adjusting for age, diagnosis of STEMI vs. NSTEMI, history of heart failure, hypertension, diabetes, coronary heart disease, cancer and other comorbidities, and for hemodynamic status on admission). Older patients with an above threshold SS had a substantially higher adjusted risk of dying in 6 months (HR 2.25, 95% CI 1.01-5.01, p=0.047). Conclusions. In unselected older STEMI/NSTEMI patients, application of PCI is dependent on specific geriatric characteristics, detectable with a multidimensional geriatric assessment approach, which independently contribute also to long-term mortality.

### A LONGITUDINAL ANALYSIS OF COMORBIDITY BURDEN AMONG OLDER ADULTS WITH HEART FAILURE

S. Ahluwalia[1], C.P. Gross[2], S. Chaudhry[2], T.R. Fried[2], *1. Veterans Administration Greater Los Angeles, Los Angeles, California, 2. Yale University, New Haven, Connecticut*

Background: Older adults with heart failure (HF) often have several comorbidities that can increase care complexity and pose a challenge to the cost-effective and patient-oriented care of this population. Our knowledge of comorbidity burden among older adults with HF remains limited, particularly how it changes over time.Thus, the purpose of this study was to describe the change prevalence of a broad range of cardiac and non-cardiac comorbidities over 6 years among older adults with HF. Methods: Retrospective, longitudinal cohort study of 201,130 Medicare beneficiaries > 65 years of age with HF, drawn from the Chronic Conditions Warehouse (CCW). We calculated annual overall prevalence of each condition within our study population from the baseline year 2001 through 2006. We also calculated annual age-stratified condition prevalence for three age cohorts (66-75 years, 76-85 years, and 86+ years). Results: 60% of HF beneficiaries had 5+ comorbidities at baseline. The prevalence of all comorbidities increased over time, with non-cardiac disease accumulating faster than cardiac disease. Non-cardiac conditions were considerably more prevalent among the oldest beneficiaries than the youngest beneficiaries. Most notably, dementia was four times more prevalent and hip fracture five times more prevalent among beneficiaries aged 86+ years, than among beneficiaries aged 66-75 years. Conclusions: The burden of comorbidity among older adults with HF increases over time; however, the profile of comorbidity changes with increasing age, with an accumulation of non-cardiac conditions among those who survive to oldest age. Findings from this study can help inform a patient-centric approach to care that focuses on managing the physical and cognitive impairments associated with age-related conditions, and to guide future service planning and cost containment efforts as the over-65 HF population ages.

## SESSION 920 (SYMPOSIUM)

### ESPO/HS SYMPOSIUM: EMERGING SCHOLARS IN HEALTH AND AGING RESEARCH

Chair: *B.D. James, Medicine, Rush Alzheimer's Disease Center, Chicago, Illinois*
Co-Chair: *B. Resnick, University of Maryland School of Nursing, Baltimore, Maryland*
Discussant: *C. Alessi, UCLA School of Medicine, Los Angeles, California*

Fostering the development of the next generation of researchers in gerontology is one of the missions of GSA. The Health Science (HS) section is proud to support this mission and to provide avenues for emerging clinical researchers and health professionals to gain experience in presenting their work to the scientific community. To that end, the HS section and the Emerging Scholars and Professionals Organization (ESPO) have sponsored this symposium, in which a multidisciplinary group of emerging HS scholars will have the opportunity to present their research and receive feedback from a panel of experienced HS board members. This impressive group of students in gerontology, nursing, and clinical psychology will present on a diverse array of topics at the forefront of research in health and aging: 1) risk factors for progression of knee osteoarthritis, 2) health and disability among cancer survivors in the Health and Retirement Study, 3) socioeconomic status and grip strength, 4) testing a function focused care intervention in nurses, and 5) neighborhood socioeconomic position and cognitive function.

### OBESITY AS A RISK FACTOR FOR PROGRESSION OF KNEE OSTEOARTHRITIS

S. O'Connor, M. Hochberg, *University of Maryland, Baltimore, Baltimore, Maryland*

Osteoarthritis (OA), a prevalent type of arthritis among older adults, is a degenerative disease in which joint cartilage deteriorates, often leading to pain, stiffness, swelling, and decreased mobility in the affected joint. Osteoarthritis of the knee is the most common type of OA, and one of the leading causes of disability among older adults. Previous literature indicates that obesity may be a causal factor in the development and progression of knee osteoarthritis, although few longitudinal studies have been cited. This study examines data from the Osteoarthritis Initiative (OAI), a prospective, longitudinal cohort study sponsored by the NIH, which aims to increase understanding of the progression and development of knee osteoarthritis. Findings of this study indicate that obesity may exacerbate the progression of knee OA, due to increased load. This study has implications for the development of public health interventions for preventing knee OA.

### DISPARITIES IN CANCER SURVIVAL AND MORTALITY AMONG OLDER AMERICANS: FINDINGS FROM THE HEALTH AND RETIREMENT STUDY

K. Garcia, E. Crimmins, *University of Southern California, Los Angeles, California*

From 2002-2006, over 75 percent of cancer (all sites) diagnoses and deaths in the United States were among adults 55 years of age and over, however, relatively little is known about the sociodemographic characteristics of older cancer survivors and the extent to which these characteristics modify the risk of cancer-specific mortality. In this study we examine cancer-specific survival over a 14-year follow-up period, using data from over 9,000 respondents in the Health and Retirement Study, aged 51 to 61 in 1992, with mortality follow-up across seven biannual survey waves through 2006. The Cox proportional hazard model and multivariate analyses are used to calculate the association between the respondent's baseline sociodemographic characteristics and cancer-specific survival. By understanding the impact of sociodemographic characteristics on cancer survival, we can identify and target high-risk groups to reduce the disparities in cancer mortality.

### GRIP STRENGTH AND SOCIOECONOMIC STATUS IN THE ELDERLY JAPANESE POPULATION

S. Davarian[1], Y. Saito[2], E. Crimmins[1], *1. Gerontology, University of Southern California, Los Angeles, California, 2. Nihon Univeristy, Tokyo, Japan*

Grip strength has been demonstrated as a useful predictor of disability, morbidity, and mortality as well as an indicator of frailty. Literature on the association between socioeconomic status and grip strength is not well developed. For the first time associations between those variables in a nationally representative sample of the 67 and older Japanese population are examined (n=2,406) using wave four of the Nihon University Japanese Longitudinal Study of Aging. It is hypothesized that less education and longer years spent in agriculture/fishery are associated with weaker grip. OLS-regression demonstrates that for every year of education overall grip increases by 0.15kg ($p<.001$), controlling for age, sex, and BMI. T-tests indicate people employed in agriculture/fishery have weaker grip (1.56kg, $p<.001$). These results demonstrate disadvantaged SES and rural occupation have negative implications in old age. Underlying mechanisms associating SES and grip strength might be similar to those associating lower SES and arthritis.

### PILOT TESTING OF A FUNCTION FOCUSED CARE INTERVENTION IN AN ACUTE CARE SETTING: IMPACT ON NURSING

M. Hammersla, *University of Maryland School of Nursing, Baltimore, Maryland*

The purpose of this pilot study was to test a motivational intervention to determine if this approach would alter nurses' beliefs and behaviors associated with their promotion of function and physical activity in older hospitalized patients. A single site pre/post test design was used with nurses recruited from 2 general medical units of an acute care hospital over a 6 month period. Twenty-three individuals consented to participate and completed baseline measures. There was a statistically significant increase (F=5.59, p=.03) in self-efficacy expectations. Although not significantly different, there was an increase in outcome expectations, knowledge of function focused care with test scores,and performance of function focused care during observed routine care interactions. The findings from this study provide some support for the feasibility of implementing a function focused care intervention in acute care in that nurses were willing to participate and engage in the educational aspects of the intervention.

### NEIGHBORHOOD SOCIOECONOMIC POSITION AND COGNITIVE MEASURES IN THE ACTIVE STUDY

S. Sisco, M. Marsiske*, Clinical & Health Psychology, University of Florida, Gainesville, Florida*

Using baseline pre-treatment data from the ACTIVE study (a multisite cognitive intervention trial on 2,802 adults aged 65+ years), the current paper examined whether relationships between neighborhood-level socioeconomic position (SEP) and cognition reported in cross-national research also hold in a U.S. sample. Using Census 2000 data collected around the time of the baseline assessment, a latent construct representing neighborhood SEP (i.e., area-level income, poverty, and educational attainment) was identified. Cognition was assessed with tasks of reasoning, verbal memory, visual attention, psychomotor speed, vocabulary, and everyday cognition. SEP evinced bivariate associations with cognitive measures ranging from r=-0.02 to r=0.33. SEP was most strongly associated with measures influenced by education/acculturation (e.g. tests of vocabulary, reasoning, and everyday problem solving), and least with measures of visual attention and psychomotor speed. Subsequent models sought to account for potential individual-level mediators of the area-level SEP-cognition associations.

## SESSION 925 (SYMPOSIUM)

### THE ROLE OF ARTS AND HUMANITIES IN MEDICAL, NURSING, AND SOCIAL WORK EDUCATION

Chair: *E. Gonzales, George Warren Brown School of Social Work, Washington University in St. Louis, St. Louis, Missouri*
Co-Chair: *R.K. Chow, National Council on Aging, Washington, District of Columbia*
Discussant: *J. Hendricks, University Honors College, Oregon State University, Corvallis, Oregon*

This multidisciplinary symposium demonstrates the critical role of the humanities and arts in facilitating empathy, dispelling ageism, raising critical consciousness, and increasing cultural competency among medical, nursing and social work students. The presenters highlight and evaluate the impact of innovative pedagogical techniques that integrate the arts and humanities into clinical education. A geriatrician discusses how written reflection exercises promote better understanding, communication skills, professionalism, and age appropriate competencies among medical students. A gerontological nurse examines use of new media (e.g., blogs, YouTube) as well as contemporary poems and paintings on aging as tools for enriching nursing education. Findings suggest that this pedagogy deepens the awareness of students for the unique and complex needs of older adults and as a result their commitment to person centered care. A geriatric social worker considers the impact of humanities and arts activities which successfully engage students in learning about domains of aging in which they had been previously uninterested. In addition to identifying strategies for incorporating the humanities and arts into clinical education, presenters assess the evidence-base and outcomes of the approaches discussed. Recommendations for future research in this emerging area of the scholarship of teaching and learning are proposed.

### ENHANCING MEDICAL STUDENT ATTITUDES TOWARD GERIATRICS: ANALYSIS OF PRE-CLINICAL STUDENT NARRATIVES

J. Powers*, Vanderbilt University, Nashville, Tennessee*

Reflection is useful to identify educational needs, develop critical reasoning and problem forming skills, and as a method to address professional challenges and to develop skills to cope with clinically complex situations. Written exercises promote better understanding and permit a commitment to learning and ownership of the experience and promote better understanding of professionalism, communication skills, and age appropriate competencies. Evolving evaluation methodology related to student journaling include identification of narrative references to professional competency domains and scoring of reflective ability. Examples of scoring techniques will be demonstrated using written, film, and digital media as well as evaluation of a course designed to enhance professionalism and communication skills for preclinical students

### GERONTOLOGIZING NURSING EDUCATION: FOCUSING ON POSSIBILITIES RATHER THAN PROBLEMS

D.J. Sheets*, School of Nursing, University of Victoria, Victoria, British Columbia, Canada*

Although nurses spend about 85 percent of their time caring for older adults, ageism is common. The impact of ageism on clinical practice and delivery of health services with poorer health outcomes is well-documented. Recent studies point to the importance of curricula that challenge stereotypes of aging through critical consciousness raising strategies. Poetry, art and new media on aging, including blogs and YouTube, that enhance and gerontologize the curricula will be demonstrated with examples of how they were used to deepen self awareness of detrimental attitudes towards older adults. Findings indicate that these pedagogical approaches in nursing education support person-centered care by transforming static stereotypical perceptions of aging into dynamic and socially critical views that take into account the heterogeneity and diversity of older adults.

### TEACHING SOCIAL WORK STUDENTS ABOUT AGING

H.Q. Kivnick*, School of Social Work, University of Minnesota, St, Paul, Minnesota*

US demographic trends mean that a large majority of social workers will find themselves working with older adult clients or with younger clients' aging family members. However, few social work students receive gerontological training as part of BSW or MSW degrees, due to a paucity of gerontological content offered by institutions, to students' lack of personal contact with elders, and to enduring and widespread attitudes of ageism. From one direction, experimental programs have demonstrated effectiveness in attracting students, providing training, and cultivating interest in and commitment to the aging population. From another direction, arts and humanities infusion in the curriculum has demonstrated effectiveness in deeply engaging students in domains of aging in which they had been previously uninterested. This presentation will highlight examples of innovations in social work educational programming, teaching, content, and qualitative student evaluation.

## SESSION 930 (SYMPOSIUM)

### VITAMIN D: SOMETHING NEW UNDER THE SUN

Chair: *D.K. Houston, Sticht Center on Aging, Wake Forest University School of Medicine, Winston Salem, North Carolina*
Co-Chair: *S.B. Kritchevsky, Sticht Center on Aging, Wake Forest University School of Medicine, Winston Salem, North Carolina*
Discussant: *M. Johnson, University of Georgia, Athens, Georgia*

Over the last two decades, our understanding of the role of vitamin D in health has extended beyond the musculoskeletal system to encompass cardiovascular health, immunomodulation, and regulation of cell growth. Vitamin D receptors have been identified in at least 36 different tissues, including skeletal muscle, osteoblasts, brain, and heart. There is also a growing list of tissues that show 25(OH)D-1-α-hydroxylase activity and can synthesize 1,25(OH)$_2$D (the active form) from 25(OH)D (the preferred indicator of vitamin D status), suggesting an autocrine or paracrine role for vitamin D. Approximately one-third of U.S. adults aged 70 years and older have low 25(OH)D concentrations (<50 nmol/L [<20 ng/mL]). This multi-disciplinary symposium examines the role of vitamin D status on aspects of health using data from the Health, Aging and Body Composition (Health ABC) Study, a prospective cohort study of 3,075 well-functioning older adults aged 70-79 years at baseline. Serum 25(OH)D was measured at the 2nd follow-up visit (n=2,793) with up to 9 years of follow-up data for the health outcomes being presented: incident depression (Williams and colleagues), incident mobility limitation (Houston and colleagues), fractures (Cauley and colleagues), and all-cause mortality (Kritchevsky and colleagues). While these observational analyses provide important preliminary evidence of the association between vitamin D status and several health outcomes, vitamin D supplementation trials are needed to definitively determine if improving vitamin D status reduces the risk of adverse health outcomes in older adults.

### VITAMIN D STATUS AND DEPRESSION IN COMMUNITY-DWELLING OLDER ADULTS

J. Williams[1], D.K. Houston[1], C.C. Davis[1], J.A. Cauley[4], S. Rubin[2], F.A. Tylavsky[3], S.B. Kritchevsky[1], K. Sink[1], *1. Wake Forest University, Winston-Salem, North Carolina, 2. University of California San Francisco, San Francisco, California, 3. University of Tennessee Health Sciences, Memphis, Tennessee, 4. University of Pittsburgh, Pittsburgh, Tennessee*

We examined the association between serum 25-hydroxyvitamin D (25(OH)D) and prevalent and incident depression in well-functioning older adults in the Health ABC Study (n=2,515). Depression was defined as a score of ≥5 on the Geriatric Depression Scale (GDS) or ≥10 on the short Center for Epidemiologic Studies Depression Scale (CES-D), or current treatment with antidepressant medication. Participant mean age was 74.7 years; 52% were women, 39% were black, and 33% were vitamin D deficient (25(OH)D<50 nmol/L). Vitamin D deficiency was not associated with prevalent depression. However, after excluding participants with prevalent depression (n=275), individuals with vitamin D deficiency were more likely to develop depression over the next 3 years (HR (95% CI): 1.54 (1.19-1.99)) compared to those who were sufficient (25(OH)D≥75nmol/L) after adjusting for age, sex, race, site, season, BMI, CVD and renal function. In summary, vitamin D deficiency may be a risk factor for depression in older adults.

### VITAMIN D STATUS AND INCIDENT MOBILITY LIMITATION IN COMMUNITY-DWELLING OLDER ADULTS

D.K. Houston[1], R. Neiberg[1], J. Tooze[1], D.B. Hausman[2], J.A. Cauley[3], D.C. Bauer[4], T. Harris[5], S.B. Kritchevsky[1], *1. Sticht Center on Aging, Wake Forest University School of Medicine, Winston Salem, North Carolina, 2. University of Georgia, Athens, Georgia, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, 4. University of California, San Francisco, California, 5. National Institute on Aging, Bethesda, Maryland*

We examined the association between serum 25-hydroxyvitamin D (25[OH]D) and incident mobility limitation in older adults in the Health ABC Study (n=2,154). Mobility limitation was defined as reporting any difficulty walking 1/4 mile or climbing 10 steps on two consecutive 6-month contacts over 6 years of follow-up (n=764). Participant mean age was 74.6 years; 48% were women, 35% were black, and 65% had 25(OH)D <75 nmol/L. Compared to participants with 25(OH)D ≥75 nmol/L, the risk of incident mobility limitation was 1.66 (95% CI: 1.36-2.02) and 1.37 (1.14-1.64) for those with 25(OH)D <50 nmol/L and 50-<75 nmol/L, respectively, after adjusting for age, gender, race, site, and season (p for trend, <0.0001). The results were attenuated somewhat after further adjustment for health habits, BMI, kidney function, and co-morbid conditions but remained significant (p for trend, 0.02). In summary, low 25(OH)D was associated with increased risk of mobility limitation in community-dwelling older adults.

### VITAMIN D STATUS AND THE RISK OF FRACTURE

J.A. Cauley[1], D.K. Houston[2], K. Barbour[1], R. Boudreau[1], D.C. Bauer[3], F.A. Tylavsky[4], T.B. Harrris[5], S.B. Kritchevsky[2], *1. Epidemiology, University of Pittsburgh, Pgh, Pennsylvania, 2. Wake Forest University, Winston-Salem, North Carolina, 3. University of Tennessee, Memphis, Tennessee, 4. University of California, San Francisco, San Francisco, California, 5. National Institute on Aging, Bethesda, Washington*

We examined the association between serum 25-hydroxyvitamin D (25(OH)D) and incident fracture in older adults in the Health ABC Study (n=2651). Fractures were ascertained every 6 months and confirmed by radiology reports over an average of 5.6 years. Mean age was 74.6y; 48% were women, 35% were Black and 34% were vitamin D deficient (<50nmol/l). Among Whites, we found no association between vitamin D and fracture. Separate analyses of hip fracture revealed similar results. Among Blacks, the relative risk (95% CI) of fracture was 0.84(0.50, 1.44) and 0.42(0.20, 1.00) in participants with 25(OH)D 50-<75nmol/l and >75nmol/l, respectively, compared to those with 25(OH)D levels <50nmol/l after adjustment for age, gender, BMI, season, alcohol and fracture history (p trend=0.057). Further adjustment for physical function measures, e.g., gait speed, attenuated these findings suggesting that at least in Blacks, higher concentrations of 25(OH)D may protect against fracture because of improvements in physical function.

### SERUM 25-HYDROXYVITAMIN D, PARATHYROID HORMONE AND MORTALITY IN COMMUNITY-DWELLING OLDER ADULTS

S.B. Kritchevsky[1], D.K. Houston[1], R. Neiberg[1], J. Tooze[1], D.B. Hausman[2], J.A. Cauley[3], D.C. Bauer[4], T. Harris[5], *1. Sticht Center on Aging, Wake Forest University School of Medicine, Winston-Salem, North Carolina, 2. University of Georgia, Athens, Georgia, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, 4. University of California, San Francisco, California, 5. National Institute on Aging, Bethesda, Maryland*

We examined the relationship between serum 25(OH)D and PTH and all-cause mortality in well-functioning, community dwelling, older adults in the Health ABC study (n=2,638; mean age, 74.7 years; 51% women; 39% black). Deaths were ascertained through semi-annual contacts over the subsequent 8.5 years (n=691). Proportional hazards models adjusting for demographics, health habits, season, physical and cognitive function, and common comorbidities showed that compared to 25(OH)D ≥75 nmol/L, mortality was elevated in individuals with low 25(OH)D (HR [95% CI]: <25 nmol/L, 2.25 [1.58-3.22]; 25-<50 nmol/L, 1.49 [1.20-1.84]; 50-<75 nmol/L, 1.25 [1.03-1.53]). Compared to PTH <23 pg/mL, individuals with PTH ≥70 pg/mL had elevated mortality (1.79 [1.32-2.42]). In models that included both 25(OH)D and PTH, both low 25(OH)D (<50 nmol/L) and high PTH (≥70 pg/mL) were significantly associated with elevated mortality (p<0.001). Stratified analyses suggested that 25(OH)D did not predict mortality in those with high PTH.

## SESSION 935 (SYMPOSIUM)

### BUILDING A MOVEMENT FOR BETTER HEALTH CARE: ENGAGING OLDER ADULTS, FAMILY CAREGIVERS AND CONSUMER ADVOCATES

Chair: *L. Feinberg, National Partnership for Women & Families, Washington, District of Columbia*

Discussant: *R. Browdie, Benjamin Rose Institute, Cleveland, Ohio*

The quality and delivery of health care services have an enormous impact on the well-being and overall quality of life for older adults. Yet, today's fragmented health care system fails to meet the fundamental needs of the most vulnerable older adults. Successfully reforming health care also is about improving how care is delivered, including transitions of care, so that the system better serves the needs of older adults and their family caregivers. This is especially critical for the 20% of Medicare beneficiaries with five or more chronic conditions who account for about 68% of Medicare expenditures. These are the people who make the heaviest use of the current system, at the highest cost, but with the poorest outcomes. Launched in 2010, the Campaign for Better Care is a consumer advocacy campaign pressing for high quality, comprehensive and coordinated care for vulnerable older adults with multiple chronic conditions and their families. Grassroots mobilization is a central element of the Campaign and key to meeting the goal of building a strong and lasting consumer voice for better health care, by engaging and mobilizing older adults and their families, and consumer advocates. This symposium will highlight the strategies being used to organize the grassroots voice of older adults and their families as activists for better care. Presenters will address key elements of the Campaign for Better Care, including messaging and communications, on-the-ground and online organizing, legal advocacy and analysis, and offer a view of the Campaign from the national and state levels.

### IMPROVING CARE FOR OLDER ADULTS WITH CHRONIC CONDITIONS AND THEIR FAMILIES: OVERVIEW OF THE CAMPAIGN FOR BETTER CARE

L. Feinberg, *National Partnership for Women & Families, Washington, District of Columbia*

The U.S. health care system is neither organized nor financed to deal with its greatest challenge: chronic illness. For many American families involved in caregiving for an older relative or friend with multiple health problems, there is deep worry about quality of care, and great frustration in the lack of communication and coordination across health providers. This presentation will provide an overview of a new multi-year initiative to change health policy and improve care, the Campaign for Better Care. It will explore the key elements of the Campaign, including the policy agenda to improve the payment and delivery of health care, educational/advocacy tactics to affect policies on chronic care, building diverse coalitions of stakeholders, and effective message development to engage older adults and their caregivers as activists for better care. The challenges and opportunities of engaging and mobilizing Baby Boomer caregivers as advocates will be discussed.

### MOBILIZING THE GRASSROOTS: STATE ADVOCACY GROUPS, OLDER ADULTS AND CAREGIVERS

R.M. Hodin, *Community Catalyst, Boston, Massachusetts*

Older Adults and their families are too often left out of state and federal debates around health care payment and delivery system reform, areas traditionally dominated by other stakeholders, such as providers and payors. It is critical that a consumer voice be powerful and engaged in order to ensure that these sorts of policy changes truly address the needs of vulnerable older adults and their families. This presentation will describe Community Catalyst's use of two integrated approaches to support the Campaign for Better Care: (1) mobilizing state-based advocacy infrastructure and (2) directly engaging and empowering older adults and caregivers. Specifically, it will discuss the coalition development and policy work of state-based campaigns in Maine, Massachusetts, North Carolina, Ohio, Pennsylvania and Wisconsin. It will also describe an innovative training program aimed at empowering older adults and caregivers as advocates who can then help support and shape their state-based campaigns for better care.

### LEGAL AND POLICY ISSUES IN PROMOTING NEW MODELS OF COORDINATED CARE

L.D. Cuello, *National Health Law Program, Washington, DC, District of Columbia*

The Campaign for Better Care (CBC) aims to improve care coordination and outcomes for vulnerable older adults with chronic conditions by changing the health care system in a way that truly puts the patient first that effectively integrates vulnerable and isolated communities into our health care system. Efforts to reform health care delivery and payment systems must pass through a complex legal matrix, including administrative authority to test new pilot programs, the creation of new laws and regulations, and the implementation of health care reforms at the federal and state level. This presentation will discuss legal and policy issues in promoting new models of coordinated care to more effectively treat chronic illness, with a special focus on how to protect health care rights and access for low-income vulnerable older adults and reduce health care disparities for minority populations in the process.

## SESSION 940 (POSTER)

## DIVERSITY AND AGING

### AN EMPIRICAL EXAMINATION OF A MEASURE OF WELL-BEING WITH OLDER LESBIANS

A.D. Ross, C.A. Waehler, *University of Akron, Akron, Ohio*

This study used Ryff's Scales of Psychological Well-being (Ryff, 1989) with lesbians (N=287) over age 60 to explore the measure's factor structure. This measure, commonly used with older adults, has not been reported with regard to lesbians. Ryff's proposed six factor structure was tested using CFA and EFA; well-being scores were also examined with other measures that may contribute to overall well-being (i.e., education, children, social support, and participation in the LGBT community) using hierarchical linear regression. The 6-factor structure did not hold for this group; as determined with EFA, a one-factor model seemed to fit these data the best. Major contributors to well-being were education, satisfaction with friends, and involvement in the LGBT community. Implications for use of this measure with lesbians are reviewed.

### THIS AIN'T SOMETHING YOU CAN PRAY AWAY

D. Stinson, *University of Michigan, West Bloomfield, Michigan*

Introduction: Increasingly, many grandparents are must care for grandchildren or face losing them to foster care. The 2000 U.S. Census shows >17,000 grandparents in Detroit, Michigan are raising their grandchildren. Many are unprepared for the accompanying challenges, which include declining fixed incomes, and struggling with added financial burdens. This novel presentation examines the major concerns facing these families, an important overlooked issue in aging in a vulnerable population. Methods: Study participants were Black grandmothers 50 to 69 years old in Project Guide, a neighborhood multi-service center program. They were trained in Photovoice research methodology and participated in the self-titled, "This Ain't Something You Can Pray Away" Project. Photovoice puts cameras in the hands of vulnerable individuals in order to document their condition and bring about social change. Grandmothers used photography to record and reflect on the personal and collective challenges faced raising grandchildren later in life. Results: The grandmothers selected photos representing their stories and situations. They identified common themes of physical space, safety, health, humiliation, faith, and resilience. Their images called attention to life lessons, hardships, and hopes for a better future. Grandmothers summarized the urgency of their needs with a six-point call to action expressed as statements/demands aimed at policymakers and civic leaders. Implications: The challenges of grandmothers raising grandchildren are rarely heard. This Photovoice project allowed the voices of Black grandmothers raising grandchildren to be heard through the camera lens. These results reveal how innovative qualitative methods can address their concerns and allow broader dissemination.

### LATINO BABY BOOMERS: THE PERSISTENCE OF HEALTH DISPARITIES

V.M. Villa[1], S. Wallace[2], M. Aranda[3], *1. UCLA/CSLA, Los Angeles, California, 2. UCLA, Los Angeles, California, 3. USC, Los Angeles, California*

California has the largest and fastest growing Latino population in the U.S. By 2050 Latinos will constitute nearly 50% of California's population (all ages) and 30% of California's population age 65+. While numerous studies have found evidence of significant social, health, and economic disparities among Latinos age 65+; there has been little investigation of the health of the Latino pre-elderly population i.e., those age 50-61. Investigation of the health and requisite social and economic disparities among the first wave of the Baby Boom population can offer insight regarding the form and content aging programs will need to take in order to meet the needs of this growing population. Utilizing data from the California Health Interview Survey (CHIS) 2007, we examine the health status of Latinos and Non-Hispanic whites age 50-61. Results reveal a persistence of health and economic disparities among the Latino population. Similar to the population age 65+, Latino baby boomers are two to three time more likely to report multiple chronic conditions and difficulty in daily functioning when compared to Non-Hispanic Whites. In fact, Latinos age 50-61 have health profiles consistent with, and in some cases worse than, Non-Hispanic whites age 65+. Additionally, Latinos are more likely to live in the deepest levels of poverty and have low education levels. Aging programs will need to provide an adequate set of health and income benefits prior to old age in order to reverse the pattern of disparities found among the Latino population.

### IMMIGRATION STRESS AND ADAPTATION: THE RESILIENCE OF THE OLDER IMMIGRANTS

J. Tan[1], N. Kagotho[2], *1. Social Work, Bridgewater State College, Bridgewater, Massachusetts, 2. Adelphi University, Garden City, New York*

This study examines the mental and physical health experiences of older adults who immigrate to the United States under the legal permanent residency status. Stressors are endemic in the immigration and resettlement process and older adults are especially susceptible to these stressors and the ensuing mental health problems. However, the older immigrants, who now make up American's fastest growing immigrant group, remain invisible to social work research literature. The data is drawn from the first wave of the New Immigrant Survey (NIS), and univariate and bivariate analysis are used to explore the immigration process among older adults. Results indicated that whereas the older immigrating adult displays mental resiliency during the visa application process, their physical health outcomes do not fare as well. Eighty nine percent of the older adult sample reported no depression symptoms associated with acquiring LPR status. In spite of undergoing a fairly stress free and uncomplicated visa application process, the Cochran-Mantel-Haenszel Statistic of general association finds a statistically significant difference between self-rating of health status prior to and after migration ($\chi 2$ (16) = 510.8, p<.0001). The percentage of respondents who rate their health as "poor" or "fair" increases from 12.5% prior to migration to 30.3% post migration. This study finds that family and social support are strong resources in this population's pre-migration experiences. Social work practitioners should therefore recognize the importance of family support and help maintain and strengthen these networks in creating health promotion strategies.

### FAMILY CAREGIVING FOR FRAIL OLDER ADULTS OF LATINO HERITAGE: THE HEALTH AND MENTAL HEALTH OF LATINA CAREGIVERS

B.M. Ramos[1], J. Jurkowski[2], B. Gonzalez[2], *1. School of Social Welfare, University at Albany, Albany, New York, 2. University at Albany, Albany, New York*

Frail older Latinos tend to be cared for by women relatives. Latinas are often their primary caregivers following traditional values of filial piety. Research indicates caregiving can be stressful and adversely impact caregivers' well-being, compromising their caregiving effectiveness. For Latina caregivers, traditional cultural values, gender, and ethnic minority status may further compromise their well-being. We examined the relationship between caregiving and well-being among Latina primary family caregivers. A health survey was administered in English or Spanish to a convenient community sample (N = 287) of adult Latinas; 30% were caregivers. Ages averaged 45, 79% were born outside the U.S., 56% self-identified as Puerto Rican, 42.3% had less than a high school education, and 51.4% were married or living with a partner and were twice as likely to be a caregiver. Regression analyses indicate caregivers were 4.3 times more likely to report a current physical chronic condition. Surprisingly, caregiving was not associated with mental health although 42.3% of the total sample reported anxiety and 39.2% depression. Furthermore, caregivers reported 65% fewer odds of currently experiencing panic attacks. The positive meanings Latino culture ascribes to caregiving may serve as a protective favor for mental health. Caregivers may have favorable perceptions of the caregiver role and might also deny caregiving stress, which could adversely impact their physical health. Research on Latina caregivers' risk and protective factors, including how they cope can inform culturally responsive policies and interventions. Support to enhance caregivers' well being can help improve the quality of life for their elders.

### THE IMPACT OF PAIN AND THE ECONOMIC DOWNTURN ON URBAN BLACK ELDERS

C.R. Green, D. Stinson, L.A. Chadiha, *University of Michigan, Ann Arbor, Michigan*

Purpose: A recent Generations article describes the U.S. economic downturn as challenging the resilience of older Americans but provided little information on minorities. The impact of the current economic downturn on the health and well-being of urban Black elders with physical and financial pain is unclear. This exploratory study was designed to gain a better understanding of pain and the recent economic downturn's impact on urban Black elders. Methods: The purposive sample (n=582) consisted of community dwelling black elderly (i.e., ≥ 60 years old) residents in greater Detroit. Participants attending an annual health reception completed a survey assessing attitudes regarding health, pain, and finances in the context of the recent economic downturn. Descriptive and bivariate analyses were conducted on participants reporting pain and those reporting no pain. Results: Compared to those reporting no pain, those reporting pain assessed their health as worse (28.6% vs. 14.1; p< .001), had trouble paying their bills (41% vs. 28%, p=.002), were having to choose between healthcare and food (19% vs. 7%, p<.001), were cutting their prescription drug spending (33% vs. 25%, p=.05), and were more likely to report being a victim of fraud than those without pain (15% vs. 5%; p=.001). Implications: These findings suggest urban Black elders' health and financial well-being may be affected by the recent economic downturn. They further suggest healthcare providers and policymakers should consider ways of assuaging the negative effects of physical pain while addressing ways to refuel the economy among vulnerable urban Black elders.

### EXPLORING RACE AND ETHNICITY IN THE MEASUREMENT OF PERCEIVED SOCIAL SUPPORT AMONG OLDER ADULTS: DIFFERENTIAL ITEM FUNCTIONING IN THE INTERPERSONAL SUPPORT EVALUATION LIST

P. Sacco, *Social Work, University of Maryland, Baltimore, Maryland*

Purpose: Perceived social support is an important construct in aging research. For example, investigators have studied social support to explain ethnic differences in health among caregivers (Pinquart & Sorensen, 2005), and outcomes in caregiving interventions (Lee, Czaja, & Schulz, 2010). Identified ethnic differences may be a result of differential item functioning (DIF), or item responses not a result of actual group differences (i.e. item bias). This study tests for DIF on one such measure, the Interpersonal Support Evaluation List (ISEL). Methods: Data were analyzed on a subsample of older adults aged 60+ (n=11,500) from the National Epidemiological Survey of Alcohol and Related Conditions (NESARC). Using Multiple-Indicator Multiple-Cause (MIMIC) modeling, DIF was tested on 12 Likert-scaled ISEL-12 items, while adjusting for socio-demographics. Results: Lower mean levels of social support were present among Asian Americans ($\gamma= -.351$; $z=-4.980$; $p<.001$) and Hispanics ($\gamma= -.115$; $z=-2.594$; $p<.01$) when adjusting for sociodemographic characteristics. Ten ISEL-12 items displayed DIF, with eight of the items less likely to be endorsed by African American and Hispanics, and two items more likely to be endorsed by African Americans and Hispanics. Once DIF effects were included, differences in social support between Hispanics and Caucasian older adults were nonsignificant, but lower mean levels of support among Asians remained significant. Implications: Findings suggest that lower ISEL-12 scores among older Hispanics may be a result of DIF, while group differences among Asians are not DIF-related. Future research should explore item properties that may be interpreted differently by older adults of different racial/ethnic groups.

## SESSION 945 (PAPER)

## INTERNATIONAL POLICY ISSUES AND AGING

### THE STRUCTURAL DETERMINANTS AND PROCESS OF ADOPTING INNOVATIONS IN COMMUNITY AGED CARE: THE CASE FOR INTEGRATED CARE DELIVERY IN NEW SOUTH WALES

L. Hixon, *University of Technology, Sydney, Broadway, New South Wales, Australia*

Using the theoretical framework of Everett Rogers' diffusion of innovations, this paper will describe the decisions about service structure that community aged care providers make in terms of what programs and services they offer. These providers are distributed across a range of seven service structures from segregated, single service, single program offerings to fully-integrated services across the aged care continuum (including residential care) and across programs. A mixed method approach is taken to investigate the adoption of fully-integrated service structures. First, data on all community and residential aged care providers in the State of New South Wales (Australia) is used to develop a multinomial logit model to identify those variables that are associated with selection into the seven various service structure types. Then, structured, narrative interviews with "early adopters" of the fully-integrated care strategy (the innovation) are used to further elucidate results from the modelling. The interviews focus on identifying both internal factors (e.g. perceptions of relative advantage, organizational values and receptiveness, leadership) and external factors policy influences, relationships with others, economics) that influence the diffusion of the innovation.

### A STUDY OF JAPANESE NURSING HOMES THAT HIRED INDONESIAN NURSING CARE WORKERS BASED ON EPA

N. Tsukada[1], T. Tatara[2], *1. Nihon University, Tokyo, Japan, 2. Shukutoku University, Chiba, Japan*

Fifty-three Japanese nursing homes hired 104 nursing care workers from Indonesia in August 2008. These care workers came to Japan based on the Economic Partnership Agreement (EPA). The major purposes of this study are to find out how administrators and program managers of the nursing homes, which have hired Indonesian care workers, would perceive their experience and to determine what sorts of problems they have encountered. The extensive-interview data, obtained from senior personnel of these nursing homes (N=18) between October 2009 and February 2010, were qualitatively analyzed. Preliminary analyses reveal that the respondents "decided to hire foreign care workers because there were concerned about the current or inevitable shortage of care workers in their institutions." Moreover, it was found that although the respondents had been concerned about the possible lack of communication skills in Japanese, about the religion (Muslim) of these people, and about their eating habits, the causes of these concerns (despite their presence) did not create any serious problems in any institution. The respondents agreed that the causes of their concerns are all manageable and could be handled satisfactorily with the use of "good management skills." The biggest problem of the Indonesian care workers turned out to be their poor skills in reading and writing the Japanese language. Something (e.g., policy modifications) has to be done about this problem immediately because they have to pass the National Care Worker License Examination, scheduled in January 2012, and if they fail to pass, they will be sent back to Indonesia.

### NETWORK INTEGRATED MODEL BASED ON CASE MANAGEMENT IN FRANCE: RESEARCH RESULTS AND POLICY ISSUES

H. Trouve[5,4], A. Veil[2], C. Yves[2], O. Saint-Jean[1,3], R. Hebert[3,6], D. Somme[1], *1. Assistance Publique Hôpitaux de Paris Hopital Europeen Georges Pompidou, Paris, France, 2. Research Center on Aging, University Institute of Geriatrics of Sherbrooke, Sherbrooke, Quebec, Canada, 3. University Paris Descartes, Paris, France, 4. University Paris Panthéon Sorbonne, Paris, France, 5. National Foundation for Gerontology, Paris, France, 6. Medical Faculty Sherbrooke University, Sherbrooke, Quebec, Canada*

A pilot program of integrated services delivery (ISD) for elderly people, based on the PRISMA methodology is ongoing in France since 2006. The PRISMA methodology was firstly assessed with success in Quebec. We reported results from the implementation study. Methods: The implementation is followed according to indicators resumed in an implementation rate. This measurement relates to the functions of the 6 tools and mechanisms of the model: coordination boards, single entry point, case-management, single assessment instrument, individualized services plan and information system. This tool is an adaptation of the implementation rate calculated and followed by a research team during the PRISMA Quebec experiment. Results: During the 18 first months, the evaluation does indicate a 15% progression of implementation, from 5% to 20%. In 36 months, the penetration rates are spread out between 50% and 60%. Contextual factors intrinsic to the French setting complexified the incorporation of integration into the public policy agenda. We identified also factors related to the background of the concerned managers and professionals and factors related to the particularities of the experiment's governance. All these factors contributed to explained the time frame of the implementation. Conclusion: This experimentation leads to consider time as the answer to important hindering contextual, professional and governance issues. This study is important because it carries important lessons learn from a first attempt to follow the implementation of the integration with a similar methodology in two very different countries.

## SESSION 950 (SYMPOSIUM)

### SRPP PRESIDENTIAL SYMPOSIUM: LONG-TERM CARE IN DIVERSE POPULATIONS: TRENDS, MYTHS AND REALITIES

Chair: *L.A. Chadiha, University of Michigan, Ann Arbor, Michigan*
Co-Chair: *D. Biegel, Case Western University, Cleveland, Ohio*
Discussant: *R. Kane, University of Minnesota, Minneapolis, Minnesota*

The U.S. aged population is witnessing unprecedented diversity across population subgroups. For instance, aged persons in some U.S. ethnic/racial minority groups (e.g., persons of Hispanic, Black or African American, Asian American origins) are projected to exceed the number of aged persons in the Caucasian group, thus raising questions about trends and patterns in transitions of aged minority persons from informal to formal long-term care settings. This SRPP Presidential Symposium focuses on the transitions of diverse aged population subgroups from informal care to formal care settings. Research documents aged persons in ethnic/racial minority groups are unlikely to transition from informal care into long-term care residential settings; however, a more recent study found African American families and elderly persons are utilizing small assisted living homes over relatively larger ones (Ball et al., 2005). Critical questions addressed by presenters in this symposium include: What are some observed trends and/or patterns in transitions from informal to formal long-term care settings among diverse aged populations? What do these trends and/or patterns reveal about myths and realities of transitions from informal to formal long-term care among these populations? What are the implications of the observed trends/patterns, myths and realities in transitions from informal to formal long-term care for aged diverse populations? The discussant, an expert in long-term care, synthesizes and reflects on content in the different presentations addressing these questions.

### SEPARATE AND UNEQUAL: RACIAL DISPARITIES IN QUALITY LONG TERM CARE

V. Mor, *Community Health, Brown University, Providence, Rhode Island*

Historically non-whites' use of nursing homes was lower than that of white elders. Over the last several decades a transformation has occurred with African Americans' rate of nursing home use exceeding whites', whose rates have been dropping with the expansion of alternatives such as Assisted Living and home care. Nursing homes remain relatively segregated, roughly mirroring the residential segregation within metropolitan areas. As a result, blacks are much more likely than whites to be located in nursing homes that have serious deficiencies, lower staffing ratios, and greater financial vulnerability. Furthermore, controlling for education and acuity, African American elders discharged from hospital to nursing home for post-acute care are much more likely to enter the home with poorer quality than is the case for whites. Finally, while nursing home closures are relatively rare, facilities in minority communities serving minority patients are much more likely to close. Persistent segregation among homes poses a substantial barrier to progress in improving the quality of nursing home care, particularly for the growing population of African American and Hispanic elders using nursing homes.

### SOCIAL DETERMINANTS OF HEALTH AND HEALTH DISPARITIES AMONG LOW-INCOME ASSISTED LIVING POPULATIONS

M.M. Perkins, M. Ball, C. Hollingsworth, C.L. Kemp, *Gerontology Institute, Georgia State University, Atlanta, Georgia*

Increasingly, the "social determinants of health" approach is recognized as an important framework for understanding and addressing health disparities among individuals, communities, and populations. This perspective moves beyond individually-focused biomedical and personal lifestyle approaches to health and acknowledges the social, environmental, economic, and political conditions that interact over the life course to shape health outcomes. Drawing on qualitative data and descriptive quantitative data collected in three studies conducted in Georgia between 1999 and 2007, we identify social determinants affecting the health of low-income assisted living (AL) residents from diverse racial and cultural backgrounds. Key areas we address include issues surrounding the growing population of elderly residents with mental illness, challenges related to increasing levels of dementia and physical impairment found in these settings, health risks associated with community-level social and economic changes, and the impact of persistent racial discrimination. We discuss findings in context to emerging trends and provide recommendations.

### CLASS, CULTURE, OR RACE? ADDRESSING DISPARITIES IN USE OF ASSISTED LIVING

M. Hernandez[1], P. Carder[2], *1. Concepts in Community Living, Inc., Clackamas, Oregon, 2. Portland State University, Portland, Oregon*

Purpose: Studies of long-term care (LTC) use in the US have reported persistent racial, ethnic and class disparities. We review existing knowledge about assisted living (AL) use by racial and ethnic minorities, propose a theoretical framework for examining disparities, and describe promising policy and practice interventions. Methods: We review findings of research on AL use and selected disparities studies in health and LTC. Results: Our review finds evidence that racial disparities in AL use may have increased as disparities in nursing home use have decreased. Policy solutions include strategies for increasing the supply of affordable AL and public subsidies and supporting research that examines policy effects between and within states. We identify environmental design and operational approaches that could make AL settings more culturally meaningful, accessible and desirable. Implications: We propose a multilevel theoretical framework for examining differences in AL use based on structural-, organizational- and individual-level factors.

### AFRICAN AMERICANS MOVE TO ASSISTED LIVING: THE ROLE OF CLASS, CULTURE, AND FAMILY DYNAMICS

M. Ball, C.L. Kemp, M.M. Perkins, C. Hollingsworth, *GERONTOLOGY, GEORGIA STATE UNIVERSITY, Atlanta, Georgia*

A number of societal trends contribute to growing diversity in the assisted living (AL) population. Despite increasing diversity, many African Americans reside in predominately African American facilities, often located in majority-black communities. Major factors contributing to segregation include: disparities in access and material resources; distrust of white institutions; and a preference among many for living among others of similar race, class, and culture. The current analysis based on ethnographic data from three studies conducted in Georgia between 1999 and the present explores variations in choice of facility and differences in the decision-making process. Interestingly, we find that some residents and families prefer more racially integrated settings. Results show that class, culture, and family dynamics are key factors that shape decisions and either limit or promote a good fit for residents. We discuss these findings in context to other factors within ALF environments that affect resident fit and make recommendations.

### CHANGES IN HEALTH AND QUALITY OF LIFE AMONG DIVERSE ELDERLY RECIPIENTS OF LONG TERM CARE

M.D. Naylor[1,3], K. Abbott[1,3], A.L. Hanlon[1], K.B. Hirschman[1,3,4], J. Prvu Bettger[1,3], C. Zubritsky[5], J. Foust[2], K.H. Bowles[1,3], *1. Nursing, University of Pennsylvania, Philadelphia, Pennsylvania, 2. University of Massachusetts, Boston, Massachusetts, 3. NewCourtland Center for Transitions and Health, Philadelphia, Pennsylvania, 4. Institute on Aging, Philadelphia, Pennsylvania, 5. University of Pennsylvania - School of Medicine, Philadelphia, Pennsylvania*

Among older adults new to the long-term care (LTC) system and admitted to one of the following LTC options — nursing homes, assisted living facilities or home and community-based services, this paper examines the natural history of changes in function, health status, and overall quality of life (QoL) during the first year of services. Data for 208 adults enrolled in these three LTC options and interviewed quarterly through 12 months were examined using mixed models with repeated measures. Functional limitations were found to increase over time and were associated with cognitive impairment. QoL ratings remain stable over time and elders with greater education report higher QoL overall. Self-rated health scores increase over time and greater education is associated with higher self-rated health scores overall. These data are the first longitudinal data available for this population. The policy and practice implications of these findings will be discussed.

## SESSION 955 (SYMPOSIUM)

### TRAINING CORRECTIONS STAFF, CORRECTIONS PROFESSIONALS, AND INMATES TO IMPROVE THE CARE OF AGING OFFENDERS

Chair: *R. Sterns, Creative Action LLC, Akron, Ohio*
Co-Chair: *A.A. Sterns, College of Nursing, Kent State University, Kent, Ohio*
Discussant: *H.L. Sterns, The University of Akron, Akron, Ohio*

The symposium will present one of the nations best examples of older adult care in a prison setting. The program will consist of presenting two training programs. The first is a web-based training program directed at staff and professionals training. The training development was funded by the National Institute on Aging. Training was assessed using a pre-test, post-test design, reaction questions, and focus groups of training participants. The knowledge gain assessment of the program demonstrates the effectiveness of learning using the web-based training. Focus groups demonstrate a culture change with a recognition of older offenders as a separate group with unique needs. The second presentation by the Assistant Warden of Angola will describe life at the prison. The prison houses the nations largest concentration of offenders with a life sentence. Many of these individuals will die in prison and be buried on the grounds of Angola. The offenders themselves have worked with staff and gerontological and medical professionals to develop programs where younger inmates provide assistance, palliative care, and hospice care to ill and dying inmates. The presentation will include pictures and video of prison life and illustrate these programs.

### THE SUCCESSFUL DEMONSTRATION OF A WEB-BASED TRAINING PROGRAM FOR CORRECTIONS OFFICERS TO BETTER MANAGE OLDER OFFENDERS

A.A. Sterns[1,2,4], G. Lax[2,3], R. Sterns[2], *1. College of Nursing, Kent State University, Kent, Ohio, 2. Creative Action LLC, Akron, Ohio, 3. The University of Akron, Akron, Ohio, 4. University of Maryland, University College, Adelphia, Maryland*

The symposium will present the results of a 3-state test of a National Institute of Aging funded education program for correction officers and professionals. The web-based training consisted of 10 30-minute modules that presented education on biological, psychological, and social aging issues related to older offenders aging in prison. The modules covered the identification of chronic illnesses, cognitive impairments, depression, and mental disorders and described changes specific to aging in prison. The training presented issues of accommodations and options for long-term care in corrections, the development of age appropriate programming, and coordination of care in the corrections setting. Results show a significant increase and learning and success in providing new and applicable information that can be used on-the-job by corrections officers. Focus group results demonstrate successful culture change and a recognition of older offenders as a unique group with unique needs.

### TRAINING INMATES TO CARE FOR AGING AND GERIATRIC OFFENDERS AT ANGOLA LOUISIANA STATE PENITENTIARY

C. Fontenot, *Angola LSP, Angola, Louisiana*

Life is life in Louisiana. Lifers are not eligible for parole and its a rare and newsworthy event when one gets pardoned. Working with such a large Lifer population has provided Assistant Warden Cathy Fontenot firsthand knowledge of challenges faced by these aging and geriatric offenders. The executive staff at Angola have responded with innovations that have been developed out of necessity. Examples of these care innovations include the conversions of dorms and the training of offender health care orderlies to accommodate the geriatric population. It is essential that we question our ability to continue to afford to house dying, old men in maximum-security prisons built for predators. The presentation will feature a presentation of the programs at Angola including pictures and video of the Angola facilities and the older inmate care program.

## SESSION 960 (SYMPOSIUM)

### URBAN AGING, HEALTH AND NEIGHBORHOOD ENVIRONMENT: EMERGING ISSUES IN RESEARCH, EDUCATION AND PRACTICE

Chair: *H. Chaudhury, Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada*
Discussant: *H. Wahl, University of Heidelberg, Heidelberg, Germany*

The growing interest in the relationship between neighborhood environment and healthy lifestyle has raised numerous questions for theory, methodology, empirical research, policy-making and practice. In the context of gerontology, the complexity of the issues are interlaced with varying abilities in mobility, differing social resources, challenges in accessibility, etc. Given the general recognition and growing understanding of the salience of neighborhood characteristics for active urban aging, there is a need for more informed research, and simultaneous and coordinated efforts to effectively and efficiently translate relevant knowledge into policy-decisions. In this backdrop of intellectual activity and knowledge-transfer challenges, the session will present four empirical studies that address the issues from multiple methodological and practice orientations. The first paper is based on a community-based participatory research employing various research methods and giving feedback to decision-makers in multiple sectors. The next study will present findings on the role of physical activity resources and neighborhood-level socioeconomic status (SES) on walking among older men. The third paper will present neighborhood profiles based on environmental audit data and findings on neighborhood supports and barriers for physical activity from the participatory method of Photo Voice. The final study focused on older adults' knowledge about social and health care services and how that might inform local policies and practices to improve seniors' ability to access information. The symposium will end with a discussant integrating the common threads in empirical findings, prioritizing areas for further inquiry and addressing the issues faced in effectively informing policy decisions and implementation.

### LIVABLE COMMUNITIES FOR AN AGING SOCIETY: FINDINGS FROM A SENIOR CAPSTONE COURSE

A. DeLaTorre, *Institute on Aging, Portland State University, Portland, Oregon*

This presentation focuses on the development of a community-based research project and findings that emerged as part of a "Senior Capstone" course at Portland State University in the summer of 2009. The course consisted of 13 students, aged 21-70, who were involved in community-based participatory research within two neighborhoods with substantially different demographics and community support systems. Collaboration with community stakeholders led to the development of group projects which adapted protocols from previously developed research instruments – e.g., the WHO's Age-Friendly Cities project and AARP's Livable Communities: An Evaluation Guide. The final qualitative research projects were uniquely tailored to each community and included: walking/rolling assessments; focus groups pertaining to age-friendly features and barriers; and oral histories. Findings were delivered to the communities and various partners capable of advocacy and implementation and focused on neighborhood form (e.g., urban design, housing, transportation), service provision (e.g., available services, volunteering), and isolated/homebound older adults.

### PHYSICAL ACTIVITY RESOURCES AND CHANGES IN WALKING IN A COHORT OF OLDER MEN

Y.L. Michael[1], L. Perdue[3], E. Orwoll[2], M.L. Stefanick[4], L.M. Marshall[2], *1. Department of Epidemiology and Biostatistics, Drexel University School of Public Health, Philadelphia, Pennsylvania, 2. Oregon Health and Science University, School of Medicine, Portland, Oregon, 3. Center for Health Research, Kaiser Permanente Northwest, Portland, Oregon, 4. Stanford Prevention Research Center, Stanford, California*

We evaluated the influence of physical activity resources and neighborhood-level socioeconomic status (SES) on walking maintenance among community dwelling older men. Participants reported time walked per day at baseline (2000–2002) and follow-up (2005-2006). Residential addresses were linked to a GIS database to assess proximity to parks, trails, and recreational facilities. Log-binomial regression analyses tested the hypothesis that men living near physical activity resources were more likely to increase or maintain time walked. Daily walking time declined by 6 minutes on average during follow-up (SD 65). Neighborhood SES modified the association of proximity to physical activity resources and walking time (P<.1). In high-SES neighborhoods, men in close proximity to parks or to trails, respectively, were 22% (95% confidence interval [CI]=1.01, 1.47) and 34% (95% CI=1.16, 1.55) more likely to maintain or increase their walking time. However, in low-SES neighborhoods, proximity to physical activity resources and walking maintenance were not associated.

### LINKING ACTIVE AGING AND NEIGHBORHOOD ENVIRONMENT: USING ENVIRONMENTAL AUDIT TOOL AND PHOTOVOICE METHOD

A. Mahmood[1], H. Chaudhury[1], Y. Michael[2], M. Campo[1], A. Sarte[1], K.N. Hay[1], *1. Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada, 2. Drexel University, Philadelphia, Pennsylvania*

The "walkability" of a neighborhood has particular relevance to maintaining independence of an ever-growing elderly population that prefer to age-in-place. The goal of this study was to examine the effect of neighborhood physical environment and social capital on the physical activity of older adults. Eight neighborhoods were selected in Vancouver, BC and Portland, OR that represent variation in residential density and mixed land-use. Profiles of these eight neighborhoods were created based on data collected through an environmental audit tool "SWEAT-R" (Seniors Walking Environmental Audit Tool – Revised) developed for this study. Photovoice technique was used to engage 64 older adults from these neighborhoods to photograph and journal their perceptions of the neighborhood environments in relation to physical and social barriers and facilitators to physical activity. Photovoice-based qualitative themes across these two regions are discussed to highlight similarities and differences between these two regions and to provide policy and planning guidelines.

### TRUST IN NEIGHBORS AND ACCESS TO SOCIAL AND HEALTH CARE SERVICES LATER IN LIFE: RESEARCH & POLICY PERSPECTIVES

A. Glicksman[1], K. Clark[1], M.H. Kleban[2], *1. Research, Phila Corporation for Aging, Philadelphia, Pennsylvania, 2. Polisher Research Institute, North Wales, Pennsylvania*

The lack of knowledge about where to find social and health care services has been associated with negative outcomes, such as poorer health, inability to remain in one's home (isn't this the same as moving to a facility – maybe you should say "age independently?), and moving to facility-based care. We examined the correlates of older persons' knowledge about social and health care services to inform local policies and practices to enhance seniors' ability to access information. We focused our investigation on the relation of knowledge about these services to the level of trust that older persons have in their neighbors (social capital). The data came from a representative sample of older (age 60+) Philadelphians. Of six measures of social capital in the data set, four showed a significant relation at the .05 level with knowledge about services. Our paper will present these results and discuss recommended policy changes city-wide and at the neighborhood levels that will strengthen social capital and increase knowledge among the city's older residents.

## SESSION 965 (PAPER)

## WORKING WITH OLDER ADULTS: HEALTH, SAFETY, AND JOB ISSUES

### OCCUPATIONAL HEALTH AND SAFETY ISSUES OF DIRECT CARE WORKERS: DOES TRAINING REDUCE WORKER INJURY?

D. McCaughey, G. McGhan, J. Kim, E. Walsh, *HPA, Penn State University, State College, Pennsylvania*

Purpose: The US Bureau of Labor (2009) identifies direct care workers as being among the occupational groups with the highest rates of workplace injury. Due to the nature of the work, DCWs are at high risk for workplace injuries and illnesses. Occupational health and safety studies have indirectly linked worker injury to negative worker and organizational outcomes such as higher likelihood of turnover. This study seeks to examine the relationship between DCW training and injury and the negative effects of DCW injury on employee job satisfaction, intention to quit, and employee willingness to recommend their facility for care and employment to friends or family. Methods: We completed a secondary analysis of data from the 2004 National Nursing Assistant Survey (NNAS), conducted by US Department of Health and Human Services (n= 3,017). Three training variables were examined in relation to injury incidents and worker and organizational outcomes. Regression analysis was performed to test for mediation and direct effects following Baron and Kenny's (1986) mediation protocol. Results: DCW injury-prevention training was significantly associated with fewer incidents of work place injuries. Higher number of injuries was significantly associated with higher turnover intent, lower job satisfaction, and decreased willingness to recommend the organization for care and/or employment. When both training and injury were added into the model, a partial mediation effect was found. Conclusion: This study offers preliminary empirical support for the importance of effective DCW training as a way to reduce injury and improve the environment for DCWs and the clients/residents receiving care.

### IS THE NURSING WORKFORCE REALLY AGING?

S. Klaus, C. Potter, B. Gajewski, *University of Kansas School of Nursing, Kansas City, Kansas*

The impact of an aging workforce is especially difficult to ascertain in the nursing profession where demand for healthcare services is expected to climb as the pool of qualified workers declines. The aim of this study was to investigate the work-unit age trends of direct care hospital registered nurses (RNs). We analyzed longitudinal unit-level data from the National Database of Nursing Quality Indicators® (NDNQI®) RN Survey across 5 years (2005-2009) to investigate aggregate RN age changes across time. Units were included if they had at least 5 RN survey responses each year (N=3,261). Hierarchical linear modeling was performed to test age trajectories by unit type across time. The overall trend of age showed an increase of 1.5 months per year. Differences in age trajectories were discovered based on unit type. Several unit types had statistically significant increases in age over time; the largest increase occurred in interventional laboratories where age increased annually by 6 months. Other units where age increased were psychiatric, ambulatory care, peri-operative, obstetrics, neonatal, pediatric, and others. Medical and surgical units became significantly younger across time; medical units decreased in age by 2.5 months per year and surgical units decreased by 1.3 months per year. No difference in age trend was found in emergency department, critical care, step down, rehabilitation, or medical-surgical units. Although some limitations exist, these findings support the proposition of an aging nursing workforce. Because the trends differ by unit type, this may demonstrate a migration of older nurses toward specific patient care units.

### STRESS PROCESS AND HEALTH AMONG AFRICAN-AMERICAN AND IMMIGRANT RUSSIAN-SPEAKING HOME CARE AIDES

V. Lukyanova, N. Muramatsu, *The University of Illinois at Chicago, Chicago, Illinois*

In metropolitan areas of the U.S., the majority of home care aides (HCAs) providing housekeeping and routine personal services for elderly are African-American women and immigrants with limited resources. Despite the diversity in this segment of the workforce, no study has compared stress-related issues among HCAs who are racial and ethnic minorities. To understand similarities and differences in the interplay among stressors, health, and health behaviors we conducted focus groups with African-American and immigrant Russian-speaking HCAs in a large Midwestern city. Results indicate that both groups experienced significant work stress due to low pay, limited benefits, insufficient training, and inadequate recognition. However, some causes of stress were different. African-American HCAs reported unique stressors related to discrimination, poverty, violent neighborhoods, child care, and unstable relationships that compounded work-related stress. Russian-speaking HCAs, on the other hand, experienced stress as a result of downgraded occupational mobility, difficult clients, and an unfamiliar work culture in addition to slow adjustment, language issues, and social isolation. In both groups, these personal and work stressors led to physical and psychological health problems, such as injury, chronic illness, and burnout. While chronic health problems motivated some of the workers to engage in health promotion activities, such as change in diet or exercise, for many of them health issues and self care were neglected or postponed due to more immediate problems. We conclude with suggestions to develop work-based support that would help native-born aides and accommodate to unique needs of immigrant workers in their transition to a new culture.

### FACTORS PREDICTING JOB TERMINATION AMONG HOME CARE AIDES: A MIXED-METHOD, LONGITUDINAL STUDY

S.S. Butler[1], M. Brennan[2], N. Simpson[1], W. Turner[1], *1. University of Maine, Orono, Maine, 2. AIDS Community Research Initiative of America (ACRIA), New York City, New York*

Despite high unemployment rates, retention of direct care workers in long-term care remains challenging for facilities and home care agencies throughout the country. When a worker leaves an organization, there are many replacement costs related to recruitment and training. At the service delivery level there is the possibility of a reduction in quality of care or potentially no care at all. This paper reports on a mixed-method longitudinal study investigating retention and turnover among workers providing personal care to clients in non-Medicare-certified home care agencies. The longitudinal design of this inquiry improves upon previous cross-sectional studies on this topic which have relied on the variable "intent to leave" as a proxy for actual turnover. A sample of home care aides (n=261) from 11 agencies serving all regions of a northern New England state were followed for 12 months over which time 70 (26.8%) terminated their employment. Binary logistic regression analysis ($\chi 2$ (2) = 14.32, p<.01) indicates factors at Time 1 predicting turnover the following year include younger age (3% less odds of termination with each year of increased age) and lack of health insurance (over twice the odds of terminating). Qualitative analysis of telephone interviews with workers soon after they left their agencies uncovered several overarching themes with accompanying sub-themes related to reasons for termination: job not worthwhile (including low pay, inconsistent hours); burn out (including difficult clients, trouble with agency); and personal reasons (including retirement, medical issues). Implications related to increasing retention of these valuable workers will be explored.

## SESSION 970 (SYMPOSIUM)

### AGING AS A TARGET FOR DISEASE INTERVENTION

Chair: *G.J. Lithgow, Buck Institute for Age Research, Novato, California*

Co-Chair: *H.M. Brown-Borg, University of North Dakota, Grand Forks, North Dakota*

Since aging is a major risk factor for human disease, targeting aging for pharmacological intervention by bring multiple benefits. The hunt for chemical compounds that delay aging in laboratory animals is well underway and the prospects for treating age-related diseases is being pursued. Do compounds that extend lifespan also extend healthspan? Will single compounds slow or prevent multiple diseases? Speakers: Monica Driscoll, Rutgers University Mathew Gill Ph.D., The Buck Institute Rafael deCabo Ph.D., National Institute on Aging, National

## SESSION 975 (SYMPOSIUM)

### AGING AND SOCIAL TIES: AN EXAMINATION OF RACIAL SIMILARITIES AND DIVERSITY

Chair: *K.S. Birditt, Institute for Social Research, Ann Arbor, Michigan*

Co-Chair: *K.L. Fingerman, Purdue University, West Lafayette, Indiana*

Social relationships are important for health and well-being especially as people age, but the majority of research has focused on White Americans. The five papers in this symposium examine positive and negative aspects of different types of social relationships and implications for well-being among diverse racial groups. Sechrist, Suitor, and Howard examined the extent to which parents differentiated among their children in the support provided and found White parents were more likely to differentiate between their children than Black and Latino parents. Fingerman, VanderDrift, Dotterer, Birditt, and Zarit examined support provided to aging parents and grown children and found that White adults provided more support to grown children whereas Black adults provided more support to parents. Brown, Bauremeister, and Orbuch assessed married couples' feelings of family closeness and found couples who reported greater closeness to in-laws were less likely to divorce although the specific associations varied by race. Sherman examined linkages between social relationships and depressive symptoms and found that White women were more disadvantaged by lack of support and more advantaged by support than Black and Native American women. Birditt and her colleagues examined daily interpersonal tensions and found White respondents showed more age related declines in reactivity to avoidance of arguments whereas Black respondents showed more age related declines in reactivity to engaging in arguments.

Overall, this symposium shows that the same basic effects of social relations occur (e.g., differentiations between children) in all racial groups but that there are variations in the types and intensity of effects.

### WITHIN-FAMILY DIFFERENCES IN SUPPORT: COMPARISONS AMONG WHITES, BLACKS, AND LATINOS

J. Sechrist, A. Howard, J. Suitor, *Purdue University, West Lafayette, Indiana*

Few studies have examined whether within-family variations in parents' provision of support to children differ by race and ethnicity. Using data on parents 40 and older from the National Survey of Families and Households (W2), we examine within-family differences in support provided to each adult child in 2,735 White, 625 Black, and 225 Latino families. Bivariate analyses revealed that White parents were more likely to differentiate among their children regarding emotional support than were Black or Latino parents; in contrast, there were only slight race and ethnic differences regarding instrumental support. These differences remained when controlling for socioeconomic and health status. Latino parents were 63% less likely than White parents to differentiate regarding emotional support, whereas Black parents were 43% less likely than Whites to differentiate regarding instrumental support. These findings indicate that despite greater need and fewer resources, parents of color are less likely to differentiate among their children.

### RACIAL DIFFERENCES IN HELP TO GROWN CHILDREN AND AGING PARENTS

K.L. Fingerman[1], L.E. VanderDrift[1], A. Dotterer[1], K.S. Birditt[2], S.H. Zarit[3], *1. Purdue University, West Lafayette, Indiana, 2. University of Michigan, Ann Arbor, Michigan, 3. Pennsylvania State University, State College, Pennsylvania*

Scholars have debated whether Black families differ from White families with regard to support of aging parents. Middle-aged adults support not only aging parents, but also grown children, and few studies have considered racial differences in support of multiple generations. Among middle aged participants (aged 40 to 60) in the Family Exchanges Study, 31% (n = 216) identified as Black and 69% as White (n = 397). Respondents reported on support they exchange with each of their parents and grown children. White middle-aged adults provided more support to grown children than Black middle-aged adults, but Black adults provided more support to parents than White adults. After controlling for participants' family structure, SES, relationship qualities and beliefs about support, effects for race became nonsignificant. Discussion focuses on cohort, social structural, and cultural factors that may contribute to racial disparities in intergenerational support.

### FAMILY-BASED TIES IN EARLY MARRIAGE AND COUPLES' MARITAL STABILITY OVER TIME

E. Brown[1], J.A. Bauermeister[2,4], T.L. Orbuch[2,3], *1. Human Development and Family Studies, University of Connecticut, Storrs, Connecticut, 2. University of Michigan, Ann Arbor, Michigan, 3. Institute for Social Research, UM, Ann Arbor, Michigan, 4. School of Public Health, UM, Ann Arbor, Michigan*

Research findings document the importance of family ties for Black Americans. Another body of research indicates that Black Americans divorce more often than White Americans, yet little is known about whether perceptions of family ties affect divorce over time and whether these effects vary by race and gender. Data were collected as part of a longitudinal study following Black American (n=199) and White American (n=174) married couples. We examined whether Black Americans reported closer family ties in early marriage than White Americans. Our survival analysis suggests that the odds of divorce decreased when both husbands and wives reported feeling close to their in-laws, but the specific results varied by race and gender. Findings are discussed in terms of couples merging families early in marriage and the unique role that family bonds play for marital stability over time.

### SOCIAL RELATIONS AND DEPRESSIVE SYMPTOMS IN AN ETHNICALLY DIVERSE SAMPLE

A.M. Sherman, *Psychology, Oregon State University, Corvallis, Oregon*

The contribution of social relations measures to depressive symptoms was assessed for a sample of Native American, African American and European American women (N=249, age range 41-89 years). Multiple regression analyses, controlling for demographic variables, showed significant interactions of racial group by support, indicating that European American women were more disadvantaged by low levels of general support and support specifically from friends, compared to women of color, and more strongly advantaged by such support when levels were high. These models account for 39% and 34% of the variance in CES-D scores, respectively. In addition, the data reveal that Native American women were particularly disadvantaged by high levels of social strain. We discuss the extension of models linking relationship dimensions and depressive symptoms to ethnically diverse samples and the continuing need to explore between-group differences.

### THORN IN MY SIDE: AGE AND RACE DIFFERENCES IN DAILY INTERPERSONAL TENSIONS

K.S. Birditt[1], K.E. Cichy[3], E. Wardjiman[1], D. Almeida[2], *1. University of Michigan, Ann Arbor, Michigan, 2. Pennsylvania State University, State College, Pennsylvania, 3. Kent State University, Kent, Ohio*

The present study examined age differences in exposure and reactivity to interpersonal tensions among White and Black Americans. Participants from the National Study of Daily Experiences II (n = 1696 White and n = 180 Black; ages 34 to 84) reported their experiences of daily interpersonal tensions and well-being (positive and negative affect) over 8 days and provided salivary cortisol samples. A total of 40% of respondents reported having an argument and 62% reported avoiding an argument. Multilevel models estimated separately for Black and White respondents revealed age related declines in exposure to interpersonal tensions. However, age differences in reactivity to tensions (e.g., appraisals, well-being, and cortisol) varied by race. White respondents showed more age related declines in reactivity to the avoidance of arguments whereas Blacks showed more age related declines in reactivity to engaging in arguments. Findings are consistent with gerontological theories of emotion regulation and the exposure reactivity model.

## SESSION 980 (SYMPOSIUM)

### AGING IN DEVELOPING COUNTRIES

Chair: *M.A. Perkinson, Saint Louis University, St. Louis, Missouri*
Discussant: *E. Rosenberg, Appalachian State University, Boone, North Carolina*

World populations are undergoing unprecedented changes in age structure due to lower birth rates and death rates associated with the "Demographic Transition." The United States and other developed nations have had over a century to deal with issues that accompany aging populations. In contrast, many developing countries are projected to have much less time to address health and social needs of growing numbers of aged. Countries still in early stages of this transition have a window of opportunity to lay the groundwork now to ensure that limited resources are used effectively and efficiently to support their older members. What are the roles and responsibilities of gerontologists from developed countries in helping to address the unprecedented demands and opportunities that accompany aging populations in less developed lands? What can we learn from developing countries that might inform our own system of services? This symposium examines aging issues in developing countries and offers strategies and guidelines for partnering with local practitioners and scholars to address those issues without imposing culturally inappropriate models of care. A demographic analysis of population aging in developing societies is followed by an anthropological analysis of the "Nutrition Transition" and aging in Kenya and India. Social gerontologists addressing health and social issues through interdisciplinary service-learning-based programs in Nicaragua, Mexico, Guatemala, and Ethiopia describe and evaluate their individual models of partnership with local educators, researchers, and practitioners, sharing strengths of each program, issues of sustainability, and lessons learned. An expert in global aging offers a summation and concluding remarks.

### A DEMOGRAPHIC ANALYSIS OF POPULATION AGING IN DEVELOPING SOCIETIES

Z. Zimmer, *University of Utah, Salt Lake City, Utah*

This presentation is intended to provide a demographic background for the symposium. Population aging will be amongst the most important demographic phenomenon of the current century. It will impact upon every region of the world and almost all countries. However, the pace of aging will vary, as will its causes and consequences, which suggest that related challenges faced are bound to diverge across the developing world. This presentation will discuss current and expected future trends in population aging in the developing world with attention paid to similarities and differences across regions and countries, and specific focus on those highlighted in other papers that are part of the current symposium. The presentation will also make reference to variations in challenges that different countries and regions are likely to face and the types of data and research that will be necessary to confront these challenges.

### CULTURAL CONTEXTS, NUTRITIONAL TRANSITIONS: THE ANTHROPOLOGY OF GLOBAL OVERWEIGHT & OBESITY TRENDS OF OLDER ADULTS

S.R. Williams[1], G. Ice[2], *1. Anthropology, Purdue University, West Lafayette, Indiana, 2. Ohio University, Athens, Ohio*

Although the undernourished still outnumber the over-fed, global rates of obesity are increasing, especially among older adults. Labeled the “nutrition transition” by Popkin and initially described in Latin American urban populations, this phenomenon appears to be spreading across the developing world. As overweight and obesity increase, a concomitant increase in prevalence of chronic diseases (e.g., cardiovascular disease and diabetes) is likely. Recent epidemiological studies report rates of overweight and obesity exceeding 70% for U.S. and South African older adults (National Social Life Health and Aging Project; WHO Study of Global Aging and Adult Health), and near 15% for aged in India (WHO/SAGE). However, these studies provide little insight into the cultural context of this nutritional transition. This paper combines in-depth anthropological data from field work in Kenya and India with population-level data, to demonstrate the importance of cultural context for understanding global trends in overweight and obesity among older adults.

### SERVICE-LEARNING AND OLDER ADULTS IN NICARAGUA: DESIGNING A PROGRAM THAT FITS

M.B. Neal[1], K. Wilson[2], A. DeLaTorre[1], *1. Institute on Aging, Portland State University, Portland, Oregon, 2. Jessie F. Richardson Foundation, Clackamas, Oregon*

Portland State University (PSU) recently received a major gift to establish an initiative, “Aging Matters, Locally and Globally,” aimed at enhancing the lives of older adults without adequate resources. The gift expands on PSU’s partnership with the Jessie F. Richardson Foundation (JFR) in an interdisciplinary service learning course on global aging and health focusing on Nicaragua. Since 2004, JFR, PSU faculty, 100+ students, and Nicaraguan government and community stakeholders have worked together to create sustainable solutions to support a growing Nicaraguan elder population. This presentation describes the program’s rationale, components, and modifications over time. Challenges (e.g., student recruitment; program cost, course content and requirements when students have widely varying backgrounds and interests; coordination of multidisciplinary faculty; in-country resources, logistics and politics) are discussed and potential solutions are offered. Strengths (e.g., the partnerships established with local and national organizations) and lessons learned for helping to assure program success are shared.

### DEVELOPING GERONTOLOGICAL EDUCATORS IN MEXICO: A PARTNERSHIP BETWEEN USA AND MEXICO

S. Ingman[1], I. Amin[2], *1. University of North Texas, Denton, Texas, 2. Gerontology, University of Louisiana at Monroe, Louisiana, Louisiana*

As low income societies experience rapid aging of their populations, they face major challenges in developing educational policies to prepare their workforce for the future. With over 50 % of the population in poverty in Mexico – mostly in rural areas – policy makers and gerontological researchers are joining forces to respond to the “senior crisis” as poverty crisis. In response to global aging across the world, we have a responsibility to assist our colleagues in younger societies to prepare for the aging of their populations. University of North Texas faculty and graduate students have joined forces with colleagues in the Guadalajara area to expand the number of the applied gerontologist in Mexico. This paper reviews the strategies we employed to reach this goal and discuss which ones were successful, e.g. informal certificates, gerontology conferences, and seminars for seniors and health care professionals in the State of Jalisco.

### GAGE: A NON-PROFIT ORGANIZATION BRINGING GERONTOLOGICAL AWARENESS TO ETHIOPIA

T.L. McMullen[1], C. Brown[2], *1. Gerontology-Doctoral Program, University of Maryland, Baltimore County, Baltimore, Maryland, 2. Seasons of Life, LLC., Parker, Colorado*

Ethiopia is the second most populous nation in Africa; however, it is one of the least developed counties in the world. Recent strategic governmental policies, used to increase life expectancy, lack balance between population growth, resources, the economy, and the age structure. The culture of caregiving is transitioning from familial to social. Further, services rendered by current non-governmental organizations are neither well known throughout Ethiopia nor available to aging individuals in many areas. To aid with these challenges, GAGE, a gerontologically focused international organization is assisting with the development and implementation of a community senior center supported within a functional gerontology certification program at Addis Ababa University. The presence of this organization may bring a greater quality of care and increase life expectancy through educating future gerontologists and the community about the effects of aging. This paper will describe current research and developmental challenges experienced while completing this international project.

## SESSION 985 (SYMPOSIUM)

### BIO-SOCIAL AND SOCIAL-PSYCHOLOGICAL ACCOUNTS OF THE LIFE COURSE

Chair: *R.M. Hauser, Center for Demography of Health and Aging, University of Wisconsin- Madison, Madison, Wisconsin*

This symposium presents a set of complementary papers on health and behavior among older adults that address both genetic and social influences on those outcomes. Two of the papers focus on possible biological sources of health and behavior, one on putative correlations between a well-known genetic marker, taq1a, and several behavioral outcomes, and a second study of the length of women’s reproductive life on overall survival. The other two papers focus on social influences on later life outcomes, one on the role of early life experiences on financial literacy in the later years and another that explains the putatively biological correlation between IQ and length-of-life by means of a simple indicator of responsibility and organization in adolescence that is only moderately related to IQ. These complementary perspectives on later life outcomes are each drawn from a common set of data, the 50+

year-long Wisconsin Longitudinal Study, which has followed the lives of Wisconsin's high school "class of '57."

### EARLY LIFE PREDICTORS OF LATE LIFE FINANCIAL LITERACY

P. Herd, K. Holden, Y. Su, *University of Wisconsin-Madison, Madison, Wisconsin*

Financial literacy skills have become of interest to researchers and policymakers as individuals are increasingly responsible for their own retirement financial planning. An era of retirement savings dominated by simple defined benefit pension plans has been replaced by defined contribution pension plans, which require significant financial literacy skills to manage effectively. But what predicts one's ability to be an effective financial planner? We focus on the extent to which early life factors, especially schooling experiences and family characteristics, ultimately impact late life outcomes. We utilize the Wisconsin Longitudinal Study (WLS) 1957-2004/5. The most recent surveys, when respondents were in their 50s and 60s, ask questions regarding their knowledge of characteristics of their pension and retirement savings. Further, there is prospective data, both self-report and administrative, on the students' schooling characteristics (i.e. IQ, high school rank, number of semesters of specific subjects such as Algebra and Geometry) and their family characteristics (i.e. family income, parental educational attainment, and parental occupation). We find that schooling experiences, in particular, are important predictors of late life financial literacy skills.

### TAQ1A AND EDUCATION, PARTISANSHIP, VOTING, AND OTHER OUTCOMES: REPLICATION ATTEMPTS USING THE WISCONSIN LONGITUDINAL STUDY

J. Freese[1], A.R. Branigan[1], R.M. Hauser[2], T. Hauser[2], C.S. Atwood[2], D.S. Benjamin[3], C.F. Chabris[5], D. Laibson[4], *1. Sociology, Northwestern University, Evanston, Illinois, 2. University of Wisconsin-Madison, Madison, Wisconsin, 3. Cornell University, Ithaca, New York, 4. Harvard University, Cambridge, Massachusetts, 5. Union College, Schenectady, New York*

Findings using molecular genetic data have recently begun appearing in prominent social science journals. Much of this is attributable to the pioneering efforts of a single study, the National Longitudinal Study of Adolescent Health (Add Health). Within medical and behavioral genetics research more broadly, the gold standard of replication in independent samples before positive findings can be taken seriously is well understood. We focus on one of the six variants genotyped in Add Health (Taq1a), and consider comparable outcomes to published findings in a different data source, the Wisconsin Longitudinal Study (WLS). Across all outcomes we consider, we fail to find associations with Taq1a. While the divergent findings might be attributable to differences between the two samples, the history of replication in genetics research and the statistical power of the respective studies suggests it is more plausible that the positive Add Health results may simply have been capitalizing on chance.

### HIGH SCHOOL ATHLETES, EDUCATION, AND COGNITIVE ABILITY IN LATER ADULTHOOD

D. Kuo, H. Han, A. Palloni, R.M. Hauser, *University of Wisconsin, Madison, Wisconsin*

Neurological evidence suggested that contact sports players were more likely to have a history of concussion which affected their cognitive ability in later life. However, social scientists found that being an athletic was positively associated with education. In the current paper, using a large group of male high school seniors in Wisconsin Longitudinal Study from 1957 to 2004, we study the relationships between being a high school athletic (football player) and the cognitive performance in later adulthood with a control for IQ in high school and education in adulthood. The sports participation was coded from the yearbooks. Education was measured at ages 36, 54 and 65. Cognitive function was measured at ages 17, 54 and 65. The preliminary findings showed that participation in sports was positively related to education at age 36, controlling for SES, IQ, grades, and aspiration. Being in football teams was the most strongly related to education.

### MAINTENANCE OF CIRCULATING SEX HORMONES CORRELATES WITH PROLONGED LONGEVITY: AN ANALYSIS OF THE WISCONSIN LONGITUDINAL STUDY

C. Atwood, J. Yonker, C. Lee, V. Chang, T. Hauser, R.M. Hauser, *Medicine, University of Wisconsin, Madison, Wisconsin*

The Reproductive-Cell Cycle Theory of Aging posits that changes in reproductive hormones associated with menopause and andropause drive our senescent phenotype (Bowen and Atwood, 2004; Gerontology, 50, 265). Supporting this, human studies have shown that higher age at menopause and last birth are associated with prolonged female post-reproductive lifespan. Utilizing the Wisconsin Longitudinal Study (WLS), we have analyzed the relationship between longevity, menopause and total reproductive lifespan in the graduate and sibling populations (n = 3720) taking into account modalities that impact 'ovarian lifespan'. There was a significant increase in longevity in those with 1) an increased total reproductive lifespan (30.93 vs. 29.41 years) and, 2) later age at last menstruation (47.01 vs. 45.71 years). Living subjects were more likely to have used HRT (62% vs. 47%). These data support the maintenance of circulating sex hormone levels in the prolongation of human longevity.

### IQ, GENDER, AND MORTALITY

R.M. Hauser, A. Palloni, *Center for Demography of Health and Aging, University of Wisconsin- Madison, Madison, Wisconsin*

Many studies have found a positive relationship between cognitive ability, as measured in childhood or youth, and subsequent survival, and several explanations of this have been offered, ranging from the idea that low ability is an indicator of adverse systemic events in infancy or childhood to the idea that high cognitive functioning is required continuously to maintain health and reduce threats to survival. The Wisconsin Longitudinal Study reproduces the basic finding that adolescent cognitive ability (IQ) is positively correlated with survival from ages 18 to 69, but there is a straightforward explanation of the relationship: High school grades account completely for the relationships between IQ and survival and have a much larger effect on survival than does IQ. That is, higher cognitive functioning improves the chances of survival because it leads to behaviors that are well organized, timely, and situationally appropriate.

## SESSION 990 (PAPER)

## DEPRESSION AND MENTAL HEALTH: CULTURAL VARIATIONS

### PREVALENCE AND CORRELATES OF DEPRESSIVE SYMPTOMS IN CHINESE OLDER ADULTS: A POPULATION-BASED STUDY

J. Li, J. Yu, *Institute of Psychology, Chinese Academy of Sciences, Bei jing, China*

Objective In China, the rapid socioeconomic transition and the consequential traditional culture change had significant influences on Chinese elderly depression. In present study, the prevalence, the potential risk and protective factors of depression for the Chinese old population were investigated. Method A cross-sectional survey was conducted with a national wide representative Chinese sample of 4945 old adults (55+ years old), and the Center for Epidemiologic Depression Scale (CES-D) was used as the measurement tool for depressive symptoms. Demographic and other self-reported related factors were taken into consideration. Results The prevalence of self-reported depressive symptoms (CES-D≥16) in the total study population was 39.86% (pre-old: 39.95%, young-old: 39.84%, old-old: 39.65%, oldest-old: 45.19%), and the CES-D score was significantly higher in the oldest-old than the three younger groups. Furthermore, multiple regression analysis indicated that age itself was not an effective predictor for depressive symptoms, whereas family support and health status explained most part of the variations of the depression. Conclusions The present study had found a higher prevalence of depression in Chinese elders compared to the prevalence rate found decades ago. Family support and health status were the most significant protective factors for Chinese elderly depression. Chinese traditional culture, which value family much and explained the previous low prevalence rate, changed significantly, and supposed to be the main reason for the current higher prevalence. In addition to the deterioration of family support, health status worse is another significant effecting factor.

### DEPRESSION: UNDER-IDENTIFIED AND UNDER-TREATED AMONG LIMITED-ENGLISH PROFICIENT PATIENTS WITH TYPE 2 DIABETES

D. Sorkin, Q. Ngo-Metzger, J. Billimek, S. Greenfield, S. Kaplan, *Health Policy Research Institute, University of California, Irvine, Irvine, California*

Research suggests the presence of diabetes doubles the odds of comorbid depression. Primary care physicians serve as the initial point of contact for most patients with depression. The under-diagnosis and under-treatment of depression may be exacerbated among ethnically and racially diverse patients because of cultural or linguistic barriers. We examined racial/ethnic differences in diagnosis and treatment of clinical depression among Vietnamese and Hispanic patients with type 2 diabetes compared to non-Hispanic white patients within primary care settings. Data were analyzed from an ethnically diverse sample of 1,026 (76% recruitment rate) Hispanic, Vietnamese, and non-Hispanc white patients with type 2 diabetes who were recruited from 6 university-affiliated medical clinics. The sample was mostly female (59.7%) with a mean age of 58.8 years (sd=11.6). Most Vietnamese (86.0%) and Hispanic (74.8%) patients spoke limited or no English. Vietnamese patients reported significantly higher rates of clinical depression compared to Hispanics and whites (p<.001). Among patients with depressive symptoms, whites were significantly more likely to be diagnosed and treated compared to Vietnamese and Hispanics patients (p<.001). Furthermore, Hispanic patients were less likely to report having seen a mental health provider in the past 12 months compared to Vietnamese and white patients (p<.001). Many patients with type 2 diabetes self-report clinical depression and yet their symptoms are not being recognized and treated in primary care settings. The under-recognition and under-treatment of clincal depression are particularly striking among Vietnamese and Hispanic patients. These findings highlight potential linguistic and cultural barriers that may contribute to these disparities.

### LIVING ARRANGEMENTS AND SUICIDAL IDEATION AMONG OLD PEOPLE IN KOREA

J. Kim[1], Y. Lee[2], J. Kang[3], *1. NORC, Chicago, Illinois, 2. University of Seoul, Seoul, Republic of Korea, 3. Yonsei University, Seoul, Republic of Korea*

We examined the relationship between living arrangements and suicidal ideation of Korean older people. Using the Social Statistics Survey conducted by the Korean National Statistical Office in 2008 (N=6,078), we first showed the prevalence of suicidal ideation by living arrangements, and then we ran multivariate logistic regressions to assess suicidal ideation. About 8% of Korean older people have a suicidal ideation. About 13% Korean single people, 5% single people with children, 6% coupled people, and 6% coupled people with children had suicidal ideation. The prevalence rate of suicidal ideation is similar for men and women except in the single people category (22% for men and 11% for women). Net of age, education, health, home ownership, and economic status, for both men and women, compared with coupled people households, single people living alone are more likely to have suicidal ideation but there is no statistically significant difference between coupled people without children and single people with children or coupled people with children. Our result may suggest that compared with other living arrangements, the single people household structure may be less likely to meet their social or economic needs, especially for old men.

### RACIAL AND ETHNIC DIFFERENCES IN THE ASSOCIATION BETWEEN SELF-RATED MENTAL HEALTH AND PSYCHIATRIC DISORDERS AMONG OLDER AMERICANS

G. Kim[1], J. DeCoster[1], D.A. Chiriboga[2], Y. Jang[2], R.S. Allen[1], P. Parmelee[1], *1. The University of Alabama, Tuscaloosa, Alabama, 2. University of South Florida, Tampa, Alabama*

This study examined racial/ethnic differences in the association between self-rated mental health (SRMH) and psychiatric disorders among community-dwelling older adults in the United States. Four racial/ethnic elderly groups were drawn from the Collaborative Psychiatric Epidemiology Surveys (CPES, 2001-2003) and included non-Hispanic Whites (n = 351), Blacks (n = 826), Hispanics (n = 406), and Asians (n = 257). All provided information on self-rated mental health and responded to a diagnostic screen. After adjustment for covariates, there were significant associations between SRMH and current diagnoses for psychiatric disorders (i.e., any mood disorder, any anxiety disorder, and any mood or anxiety disorder) among older non-Hispanic Whites, Blacks, and Hispanics but not among Asian elders. The predictability of SRMH to diagnoses for psychiatric disorders was strongest in the non-Hispanic White sample. Racial/ethnic variations were found in the relationship between self-perception of mental health and DSM-IV psychiatric disorders. The findings suggest the need to develop race/ethnicity-specific strategies to screen psychiatric disorders in diverse elderly populations. Further exploration of how emotional distress is expressed within the diverse racial/ethnic groups is needed to improve access to quality mental health care.

## SESSION 995 (SYMPOSIUM)

### AGHE PRESIDENTIAL SYMPOSIUM: ENVIRONMENTAL TRANSITIONS AND THE MEANING OF HOME IN OLD AGE: EDUCATIONAL PERSPECTIVES

Chair: *G.D. Rowles, University of Kentucky, Lexington, Kentucky*

This internationally-focused AGHE Presidential Symposium brings together leading scholars from England, Ireland, Germany, Canada and the United States to explore the meaning of home in the context of relocation in old age. A growing body of literature confirms the relationship between “being at home” and wellbeing. Relocation resulting from transitions in the level of needed care typically disrupts this experiential person/place relationship with negative consequences for both physical and psychological wellbeing. Information on strategies to mitigate the stresses of relocation is limited. In this symposium we discuss education-related interventions that can facilitate maintaining a sense of home in the context of relocation. Within this rubric, the contributors utilize theoretical and empirical research conducted in several Western countries to critically explore five interwoven themes: (1) dimensions of the meaning of home in old age; (2) changes in the meaning of home resulting from relocation in response to transitions in care needs; (3) innovative education-based interventions to ease the process of relocation that focus on maintaining, transferring,creating or re-creating a meaningful sense of home; (4) the need to train human service and care professionals to greater sensitivity to the meaning of home and its implications for the manner in which older people accommodate to relocation; and (5) the potential for using a focus on the meaning of home for older people as an educational portal for gerontology students to gain insight into and appreciation for the role of place in the lives of older people.

### EDUCATING FOR THE LATE-LIFE LIVING AND CARE CONTEXT: WHAT CAN WE LEARN FROM URBAN HOUSING IN VERY OLD AGE?

F. Oswald[1], H. Wahl[2], *1. Interdisciplinary Ageing Research, Faculty of Educational Sciences, Goethe University Frankfurt, Frankfurt, Germany, 2. Institute of Psychology, Dept. of Psychological Ageing Research, University of Heidelberg, Heidelberg, Germany*

The European project ENABLE-AGE continues to address the role of home environments in advanced old age. We rely on key findings and link them with educational challenges across the lifespan. First, we found that functional and experiential aspects of the home go together across research sites and are similarly related with endpoints of autonomy and depression. Second, home adaptation and relocation from home to home is rare in those very old urban elders, although variation across countries occurs. Third, qualitative analyses show subtle forms of societal participation, although active community involvement decreases. Finally, longitudinal quantitative analysis revealed that functional housing aspects were predictive for change in autonomy and depression. Subsequently, understanding the intertwined nature of the functional and experiential home must enter professional care and counselling curricula. Further, the lifespan task of preparing for home alternatives most suitable to preferences of present and future cohorts of elders should find an echo in our societies educational pathways.

### RELOCATION WITHIN AN ENGLISH RETIREMENT COMMUNITY: REMAKING PLACE DURING A TIME OF CHANGE

T. Scharf[1], J. Sim[2], B. Bartlam[2], M. Bernard[2], J. Liddle[2], *1. National University Ireland Galway, Galway, Ireland, 2. Keele University, Keele, United Kingdom*

This paper examines remaking of place by older people during and after relocation to new accommodation as part of the major redevelopment of their community. Data derive from the mixed-methods Longitudinal Study of Ageing in a Retirement Community. Quantitative changes in health status, quality of life and loneliness over a two-year period were compared between residents who had relocated (n=19) and those who had not (n=53), controlling for relevant baseline variables. Additionally, 15 qualitative interviews were completed with 8 residents during the relocation process: pre-move; on first viewing of their property; and post-move. While quantitative differences between the two groups of residents were small ($\leq$ 8% of the total scale for each measure) and statistically non-significant ($p \geq .131$ in each case), qualitative findings highlight the complex relationships people have with their living environments. The paper concludes by discussing the implications for educating and supporting people during such a transition.

### PLACE INTEGRATION AND HABIT: CONCEPTS CENTRAL TO MEANING IN RESIDENTIAL TRANSITIONS

M. Cutchin, *University of North Carolina at Chapel Hill, Chapel Hill, North Carolina*

The transition from one home to another is often a difficult challenge for older adults, but it is a challenge that shares generic traits with other problematic situations we face in life. Drawing on research with people in adult day centers and assisted living residences as well as a trial of an intervention with at-risk older people in their homes, I will discuss the concepts of place integration and habit as central to understanding residential transitions and the creation (and re-creation) of meaning for seniors. These concepts, based on John Dewey's philosophy of experience, provide useful ways to interpret the process of residential transitions. Moreover, the concepts provide the basis of educational interventions that can foster the integration of older people with new environments and their development of meaning and quality of life. That basis of intervention and its implications will be discussed.

### TAKING 'HOME' WITH YOU WHEN LEAVING 'HOME': STRATEGIES IN TRANSFERENCE OF MEANING OF HOME

H. Chaudhury, *Gerontology, Simon Fraser University, Vancouver, British Columbia, Canada*

Relocating from one's home to a care facility or assisted living can be an emotionally challenging experience. Are there practical ways in which the meaning of home is transferred and/or recreated in an institutional environment? The presentation will illustrate a few methods in which older adults, caregivers and professionals could be sensitized and educated toward that goal. The process of understanding and implementation can be characterized as having three stages: recognition of opportunities, planning for the activities and implementation. Opportunities with older adults and/or their family caregivers would include creation of "home-stories," "home-leaving-ritual," and identifying objects of meaning. Formal caregivers and design professional could employ methods based on activities and design to support the meaning of home. These include home-themed reminiscence, art as a medium to connect with the meaning of home and physical environmental design based on home and home-based activities. Potential challenges associated with implementation of such methods will be highlighted.

### THE HOMES OF OLDER PEOPLE AS TEACHING TOOLS FOR GERONTOLOGY STUDENTS

R.L. Rubinstein, K. de Medeiros, *UMBC, Baltimore, Maryland*

Fundamental in the teaching of gerontology students at any level is an appreciation of the biographical or life course approach to aging. We believe that it is difficult to understand the present-day life of a person without understanding that person's history. One way of accessing this history is though the discussion of personal objects and spaces in the home. In a sense, the home acts as a repository for a person's life history through objects, photos, moments, and the like. In addition, students who meet elders in their home keep detailed field notes on physical characteristics of home such as neighborhood, arrangement of furniture, and other impressions of place. Gerontology students can begin an appreciation of the lives of elders through an appreciation of such worlds.

## SESSION 1000 (SYMPOSIUM)

### EXPRESSIONS AND EXPERIENCES OF RESILIENCY IN PERSONS WITH DEMENTIA

Chair: *L. Snyder, Shiley-Marcos Alzheimer's Disease Research Center, University of California, San Diego, La Jolla, California*
Discussant: *L.P. Gwyther, Duke University, Bryan Alzheimer's Disease Research Center, Durham, North Carolina*

People with Alzheimer's disease and related dementias are often equated with terms that are synonymous with cognitive decline, functional failure, and the disintegrating loss of self. Indeed, the very word "dementia' means "without mind." These social and scientific constructs obstruct our capacity to explore and affirm the ways in which persons with dementia exert behavioral and psychological coping abilities and enduring expressions of selfhood throughout the disease continuum. This symposium illuminates the capacity of persons with dementia to both experience and express resiliency, and underscores circumstances that can threaten capacity for resiliency. Sabat provides a theoretical overview of how Social Constructionist theory can help to conceptualize the ways in which persons with Alzheimer's reveal enduring aspects of self and resiliency along the disease continuum. Harris examines resiliency as a behavioral process that might be learned and promoted as illustrated through case studies. Samsi analyzes in-depth narratives of persons with dementia and their care partners to reveal the role of resiliency in effective coping. Finally, Logsdon discusses quantitative data on the effects of support group participation for people with early-stage Alzheimer's and explores the potential of this model to enhance resiliency. Together these four presentations deepen our awareness of experiences and expressions of resiliency in persons with Alzheimer's and help to inform our practice with this population. This symposium is sponsored by the Alzheimer's disease interest group.

### RESILIENCY OF THE SELF IN PERSONS WITH DEMENTIA

S.R. Sabat, *Psychology, Georgetown University, Washington, District of Columbia*

Although it has been alleged that dementia entails a "loss of self" (see Eisdorfer and Cohen), the allegation itself has been made on the basis of the fact that people with dementia have problems recalling their life narratives. Thomas Reid, centuries ago, dispelled the notion that selfhood depended upon recollection of one's life events. In recent years, it has become clear through the use of qualitative approaches, case studies, and the application of a Social Constructionist approach to understanding different aspects of selfhood, that people with Alzheimer's disease can retain many aspects of selfhood even in the moderate to severe stages of the disease as defined by standard measures. The resiliency of the self is not dependent on recollection of life events, but rather upon the interdependency of persons—those diagnosed and those who are their care partners. This presentation will provide concrete examples of this phenomenon

### IS RESILIENCE A KEY TO LIVING A MEANINGFUL LIFE WITH DEMENTIA? FACTORS THAT CONTRIBUTE TO THE RESILIENCE PROCESS IN PEOPLE WITH EARLY STAGE DEMENTIA

P. Harris, *Sociology, John Carroll University, Cleveland, Ohio*

This study examines the concept of resilience as a behavioral process, not as a personality trait. Thus, resilience should be able to be learned and environmental conditions promoted to nurture it. By applying a resilience framework, with its concepts of assets, protective factors, risks, and vulnerabilities, to the case studies of 6 people living with early stage dementia, some doing well and some struggling, differences between the two groups can be identified. Multiple risks and vulnerabilities, such as other serious healthcare problems and various family concerns were present in all case studies. However, differences between the two groups lie in their assets and protective factors, such as: acceptance of changing views of self, motivation to find new ways to remain a contributing member of society, a positive attitude, and an affirming person-centered or relationship-centered environment, which counterbalanced individuals' risks and vulnerabilities. Practice implications of these findings will be discussed.

### RELATIONSHIP BETWEEN RESILIENCY AND COPING IN PERSONS WITH DEMENTIA

K. Samsi, J. Manthorpe, *Social Care Workforce Research Unit, King's College London, London, United Kingdom*

Qualitative studies exploring the experience of change in dementia has identified a variety of coping techniques used by people with dementia. Most of these have been conceptualized as strategies consciously employed to incorporate dementia into everyday lives. The current study adds to this evidence base by highlighting the role of resiliency and mental strength, or life-long personality traits and characteristics as unconscious coping styles. In-depth narratives of people with dementia and their carers revealed the power of resilience in enabling people to cope with their condition. Resiliency was demonstrated through individuals reflecting on their levels of autonomy, focusing on experiences in the past which had been more challenging than the current situation, their ability to focus on positives in their lives, and to remain cheerful. Resilience enabled people with dementia to feel a sense of continuity in their lives, and ultimately contributed to a sense of overall well-being.

### ENHANCING RESILIENCY IN EARLY STAGE DEMENTIA: BENEFITS OF SUPPORT GROUP PARTICIPATION

R.G. Logsdon[1], K.C. Pike[1], S.M. McCurry[1], P. Hunter[2], J. Maher[2], L. Snyder[3], L. Teri[1], *1. University of Washington School of Nursing, Psychosocial & Community Health, Seattle, Washington, 2. Alzheimer's Association Western and Central Washington State Chapter, Seattle, Washington, 3. Shirley-Marcos Alzheimer's Disease Research Center, University of California, San Diego, California*

Individuals with early stage dementia and their families have identified a need for education and support in coping with psychosocial and lifestyle changes. This presentation describes a randomized controlled trial comparing an Early Stage Memory Loss support group program (ESML, $n = 96$) to a wait list control condition (WL, $n = 46$). Mean age of participants was 74.9; mean MMSE was 23.4. On the intent-to-treat analysis, ESML participants reported significantly improved quality of life compared to WL participants ($p < .001$). Self efficacy and mental health were significantly improved in ESML participants reporting improved quality of life compared to ESML participants reporting no change or decreased quality of life (both $p < .01$), as were family communication, emotional and social functioning, depression and behavior problems (all $p < .05$). These results support the efficacy of ESML support groups and provide information about ways in which groups enhance resiliency.

## SESSION 1005 (POSTER)

## FAMILY CAREGIVING I

### SLEEP DISTURBANCES IN ALZHEIMER'S DISEASE AND CAREGIVER MOOD: A DIARY STUDY

A.M. Akerstedt, *Clinical Psychology, University of Massachussetts Amherst, Amherst, MA*

Caring for a family member with Alzheimer's disease (AD) is associated with significant stressors and negative consequences, including psychological and emotional distress (Belle et al., 2006; Schulz & Martire, 2004). One of the most problematic stressors for family caregivers is patient sleep disturbance (Hope, Keene, Gedling, Fariburn, & Jacoby, 1998; Pollack & Perlick, 1991). Whereas the impact of patient sleep disturbance on general measures of negative affect has been established, no prospective diary studies have been conducted and the effect of daily sleep disturbance on daily negative moods is not known. The current study examines the impact of AD patient sleep disturbance on the daily positive (PA) and negative affect (NA) of their family caregivers. Data collection is on-going and participants are caregivers ($N=40$) living with a family member with AD. Caregivers are interviewed about their own and their patient's mood, sleep, stress and physical activity twice daily for eight days. Sufficient data for analyses will be collected by the GSA meeting. Hierarchical linear modeling (HLM) will address the hypothesis that poor patient sleep is associated with increased daily NA and decreased daily PA. Because poor sleep is associated with an increase in NA and a decrease in PA (McCrae et al., 2008), caregiver sleep will be examined as a mediator between poor patient sleep and caregiver daily mood. Improving patient sleep could prove to be a beneficial target for treatment that could have a positive impact on caregivers' daily mood and well-being, and potentially improve the quality of care.

### EMOTION WORK IN INFORMAL CAREGIVING FOR PERSONS WITH DEMENTIA

C. Simpson, G. Acton, *School of Nursing, University of Texas, at Austin, Austin, Texas*

Emotion work refers to efforts made to enhance emotional well-being and provide emotional support in a relationship between two people. Emotion work is an important variable in family work but has not been described in the work done by family members caring for a person with dementia. The study presented is an initial step in understanding how emotion work can be identified as a part of the caregiving experience. Content analysis was applied to 11 interviews of informal caregivers. While emotion work was not the subject of these interviews, evidence of emotion work was found in each interview. Five categories of emotion work were identified: 1) managing feelings, 2) overriding feelings; 3) weighing options, 4) being parental and 5) ensuring well-being. Both men and women performed emotion work and expressed feelings of incongruence and some strategy for managing emotions. Female caregivers performed more emotion work than male caregivers. Daughters performed the most emotion work. These findings suggest emotion work is a part of family work for caregivers. Further research is needed to understand how emotion work changes in a relationship when one person has dementia; do the changes create stress and negative health outcomes; and can interventions be designed to reduce stress through improved strategies for emotion work?

## FAMILY CAREGIVER EXPERIENCES WITH PROGRESSIVE DEMENTIA: A PILOT STUDY

C. Stewart, J.S. Wilson, *College of Nursing, University of Oklahoma, Tulsa, Oklahoma*

The chronic progressive nature of cognitive and functional decline in persons with dementia creates progressively higher demands for caregivers. For community-dwelling older adults diagnosed with dementia, there are one or more caregivers that provide an increasing amount of complex tasks at tremendous physical and psychological expense. As the population ages, the number of individuals diagnosed with dementia continues to increase. An estimated 5.3 million Americans have been diagnosed with Alzheimer's which is now the 6th leading cause of all deaths in the United States and the 5th leading cause of death in people over the age of 65. Caregivers, which are usually family members, supervise and eventually assume responsibilities for the dementia patient and assist them to retain as much independence as possible. A systematic review of the literature was done to identify trends in dementia caregiver research which included physical and psychological illnesses, burden, depression, and placement in long term care, among many others. Gaps identified include older adults, ages 65-99, serving as primary caregivers for the older adult with dementia and successful management strategies implemented by these caregivers. This qualitative study will seek to examine the effective ongoing management of community-dwelling older adults being cared for by an aging caregiver.

## THE EFFECT OF CAREGIVING ON MARITAL SATISFACTION: ACCULTURATED VS. NON-ACCULTURATED ARMENIAN WOMEN

G. Mkrttchian, R. Giarrusso, *Sociology, California State University-Los Angeles, Los Angeles, California*

Research has shown that caregiving has a negative effect on marital satisfaction; however, most research has been based on white samples and has ignored the possible moderating effect of culture. In the Armenian culture, women are expected to provide care to family members in need. Therefore, it is likely that the negative relationship found between marital satisfaction and caregiving found with white samples does not hold for traditional Armenian women. However, a negative association between marital satisfaction and caregiving would be expected for Armenian women who have become acculturated to the American culture. The purpose of this study is examine the possible moderating effect of ethnic culture on the relationship between family caregiving and marital satisfaction among Armenian women between 35 to 60 years of age who are caregiving for one or more family members (parents, parents-in-law, children, and/or grandchildren. A convenience sample of 110 Armenian females was selected from two Armenian Christian churches in southern California. The results revealed that Armenian women are not only "sandwiched" between parents and children in their family caregiving responsibilities but also between parents and grandchildren. Further, many Armenian women are also "sandwiched" between parents-in-law and other family members. As hypothesized, family caregiving only has a significant negative on marital satisfaction when the women are highly acculturated to the dominant American culture; otherwise, family caregiving has little to no negative effect on marital relationships. The findings are discussed in terms of the moderating influence of ethnic culture on marital satisfaction.

## EMERGING ADULTS' CAREGIVING EXPERIENCES AND PREPAREDNESS FOR FUTURE CAREGIVING

J.J. Benson[1], L.A. Snyder[1], J. Krampe[2], M.L. Matteson[2], *1. Human Development and Family Studies, University of Missouri, Columbia, Missouri, 2. University of Missouri School of Nursing, Columbia, Missouri*

Care demands of older adults continue to grow as the size of this age group expands. United States policy places the majority of the burden for caregiving of older adults on family members. Thus, current research on caregiving has devoted much attention to the implications of caregiver preparedness on caregiver burden and care-recipient well-being. Caregiving studies have primarily focused on care provided by adult children to their aging parents while research rarely explores the caregiving experiences of young adults (aged 18-25). No known research explores the relationship between emerging adults' prior interactions with the caregiving experience and their preparation for future caregiving of their parents. To address this gap in the literature, the current study investigated how emerging adults' gender, observations of their mother's parental caregiving, and their own performance of care tasks, influence preparedness for caregiving of their own mothers. Data were drawn from a sample of 233 college students who completed a survey focused on their past caregiving experience and preparation for future caregiving. Data analyses revealed that students' gender and observations of caregiving were not significant in predicting preparedness for caregiving. However, students who assisted with or performed a greater number of care tasks perceived themselves as significantly more prepared to provide care than their peers with less hands-on caregiving experience. These findings illuminate the need for practitioners to consider the influence previous encounters with caregiving may have on emerging adults' preparedness for future parental caregiving. The need for further exploration of emerging adult caregivers is discussed.

## THE EFFECTS OF POSITIVE INTERACTIONS ON CAREGIVER WELL-BEING

C.A. Sofko, A.M. Reamy, J. Lee, S.H. Zarit, *The Pennsylvania State University, State College, Pennsylvania*

Much of the focus in caregiving research has been on behavior problems and other stressors, but there is increasing interest in the positive experiences of caregivers. One potentially important factor is positive interactions between caregivers and care receivers. When caregivers and care receivers interact in pleasant or enjoyable ways, this may enhance caregivers' well-being or buffer the negative effects of care-related stressors. This study examines the association of positive interactions to care-related stress and caregivers' well-being in a sample of 234 family caregivers of individuals with dementia. Caregivers were interviewed about care receivers' current behavior problems in the past week, as well as, the frequency of positive interactions between them. Dependent measures were overload, depressive symptoms, and anger. Using multiple linear regression, we found that frequency of behavior problems and positive interactions contributed independently to each of the dependent measures. Increases in frequency of positive interaction were negatively associated with overload, depressive symptoms, and anger, while behavior problems had a positive association with these same outcomes. Tests of whether positive interactions might buffer the effects of behavior problems were not significant. These findings contribute to the growing literature on the importance of positive interactions in caregiving and suggest that improving daily interactions may enhance the caregiving experience for both caregivers and care receivers.

### SUBJECTIVE CAREGIVER BURDEN AND NEEDS OF CAREGIVERS FOR SENIORS WITH NEUROLOGICAL DISEASE

J. Bibbo, *California State University, Chico, Chico, California*

This study explored the needs of informal caregivers for seniors with neurological disease. The aim was to better understand factors impacting caregiver burden over time in order to more effectively serve this valuable and expanding population. The population was selected from cases that had begun receiving services from a Caregiver Resource Center in northern California from 2004 – 2008. Research was conducted using data from the center's archives. Objective and demographic factors that may have contributed to subjective caregiver burden were examined. Major problems and needs identified by the caregivers were also considered. Subjective caregiver burden was assessed using the Adapted Zarit Burden Interview. Results of a Wilk's Lambda ($p < .001$) indicated that burden significantly decreased from intake to 6-months and 1 year. These results indicate that such individually tailored programs are useful resources for informal caregivers.

### EXAMINING THE FEASIBILITY OF RECRUITING ADOLESCENTS LIVING IN ALZHEIMER'S CAREGIVING FAMILIES

C. Mitchell, E.K. Stevens, *Case Western Reserve University, Cleveland, Ohio*

Research on older adults with Alzheimer's disease suggests that the caregiving experience impacts not only the primary caregiver, but also the entire family system. Many older adults diagnosed with Alzheimer's disease live with their primary caregiver, and this caregiver is often an adult child living with his or her own spouse and children. Adolescents living in a home with a grandparent with Alzheimer's often participate in the caregiving process, but relatively little is known about the experiences of these adolescents. Research also indicates that adolescents have positive experiences related to caregiving, although it is likely that stress experienced by a caregiving parent spills over and is also experienced by these adolescents. In order to better understand the experiences of adolescents living with a grandparent with Alzheimer's, the present study sought to recruit adolescents living in Alzheimer's caregiving families and to employ a strength-based journaling intervention completed twice a month, over a two month period. After intense recruitment efforts over a period of approximately one year, eight adolescents were successfully recruited. Recruitment occurred nationally and locally, via calling branches of the Alzheimer's Association, churches, senior centers, a caregiver registry, and an Area Agency on Aging. The present study demonstrated that the feasibility of recruiting adolescents living in Alzheimer's caregiving families was quite low given the recruitment effort. Before developing interventions targeted at adolescents living in Alzheimer's caregiving families, future studies should consider alternative means of identifying and collecting data from this population.

### DEMENTIA CAREGIVERS AND COPING STRATEGIES: RELATIONSHIP TO HEALTH AND WELL-BEING. THE CACHE COUNTY DEMENTIA PROGRESSION STUDY

C. Snyder[1,2], C. Smith[1,2], L.S. Lee[1,2], M.C. Norton[3,2], K. Piercy[3,2], E.B. Fauth[3,2], S. DeBerard[1], J. Tschanz[1,2], *1. Dept. of Psychology, Utah State University, Logan, Utah, 2. Center for Epidemiologic Studies, Utah State University, Logan, Utah, 3. Dept. of Family, Consumer, and Human Development, Utah State University, Logan, Utah*

Emotion-focused coping strategies have been associated with negative psychological outcomes among caregivers. Using linear mixed models, we examined change in caregiver coping strategies over the course of providing care to persons with dementia, and whether coping strategies predicted caregiver anxiety and occurrence of medical conditions in a population-based study of dementia progression and caregiving. Dementia caregivers (N = 312; 74% female, 43% spouses, 49% adult children, 8% other relatives/friends) were assessed annually (maximum = 5.67 years). Mean (SD) age and educational attainment were 67.68 (14.13) and 14.14 (2.38) years, respectively. Caregivers completed the Ways of Coping Checklist-Revised, Beck Anxiety Inventory, and questions regarding health concerns at each visit. Providing care was the most frequently reported type of problem identified by caregivers. While the use of most coping strategies was stable over time, compared to the "other caregiver" group, adult children reported increased use of Blames Self and Avoidance while spouses reported increased use of Seeks Social Support (all interactions, $p < 0.05$). On average, greater use of Wishful Thinking and Blames Self was associated with higher caregiver anxiety (p's < 0.002). On average, increased use of Blames Others among males (interaction, $p = 0.02$) and increased Wishful Thinking among younger caregivers (interaction, $p = 0.01$) was associated with a higher number of medical conditions. Coping strategies did not affect rate of change in either anxiety or medical conditions. Our results emphasize the importance of caregiver coping strategies on caregiver well-being and may suggest avenues for effective caregiver interventions.

### DEMENTIA CARE RECIPIENT AND CAREGIVER PERCEPTION OF DECISION MAKING AND ITS EFFECT ON CARE RECIPIENT QUALITY OF LIFE

H. Moon[1], C.J. Whitlatch[2], A.L. Townsend[1], *1. Case Western Reserve University, Cleveland, Ohio, 2. The Benjamin Rose Institute, Cleveland, Ohio*

Few studies have examined the similarities and differences between dementia care recipients (CRs) and caregivers (CGs) in their perspectives about CR's involvement in decision, and the effect on CR's quality of life. This study examines difference between CR's and CG's report about CR's involvement in decision about his/her daily care (15 items-DMI: Menne & Whitlatch, 2007) and the effect of this difference on CR's quality of life (13 items-QoL; Logsdon et al., 1996). Within 215 care dyads of CRs with mild to moderate Dementia and CGs, in 25%, CG reported CR is more involved than CR did, and in 65% CR reported CR is more involved than CG did. In the remaining, in 10% there is no difference. In OLS, simultaneous multiple regression, CG quality of life was significantly lower in dyads where CG reported more CR's involvement than CR did ($B= -2.87$, $p=.02$) compared to dyads where there is no discrepancy in perspectives. For dyads, where CR reported more involvement than CG did, there was no significant effect on CR quality of life. Regression results control for other characteristics such as gender and kin relationship ($R2 = .17$, $p<.001$). One implication of these findings is that enhancing CG and CR communication about the CR's involvement in decision making may promote CR quality of life. Discussion will focus on strategies for improving communication between CRs with early-stage dementia and their family caregivers.

### ALZHEIMER'S DISEASE AND TRANSITIONS OF CARE: THE LOSS OF THE FAMILY CAREGIVER ROLE

A. Gentz, C. Fruhauf, *Human Development and Family Studies-Marriage and Family Therapy, Colorado State University, Fort Collins, Colorado*

Family caregiving for adults with Alzheimer's disease is an important issue that affects many individuals. When caregivers are no longer caregiving, the loss of the role may impact their life. However, it is unknown in the gerontological literature how the loss of the caregiver role is experienced. The purpose of this research was to understand the loss of the caregiving role of family caregivers who provided assistance to individuals who had Alzheimer's disease. A total of 21 participants age 41 to 88 participated in one focus group (i.e., three focus groups were conducted with 5 to 10 participants) addressing the loss of their caregiver role. Many participants (n = 18) were female and were caring for a parent/in-law (n = 14). A third of caregivers provided care for 5 to 8 years. Qualitative data analysis techniques were used to develop themes and codes to understand the experiences of previous caregivers. Two themes emerged from the data: caregiving journey and standing at a cross-road. Data focusing on the caregiving journey addressed rewards and stumbling blocks during and after active caregiving. For example, participants discussed tools and feelings associated with providing care. Standing at a cross-road illustrated four sub-themes: unforeseen happenings, unexpected phase of caregiving, caregiver's sense of self, and grief/sadness. Future researchers should consider examining gender differences and the loss of the caregiver role for children versus spouses. Professionals should consider developing educational materials and support groups focusing on the loss of the caregiver identity.

### WHAT AFFECTS DEMENTIA PATIENT CAREGIVER WELL-BEING?

K.H. Lonergan, K. Vo, V. Samarina, F. Moise, R. Gomez, *Pacific Graduate School of Psychology at Palo Alto University, Palo Alto, California*

Objective: Using baseline data of 643 dyads from the REACH II (Belle et al., 2006) study, the effect of social support on the relationship between dementia patient impairment and caregiver well-being was examined. Methods: Care-recipient impairment was measured using the MMSE (Folstein et al., 1975), RMBPC (Teri et al., 1992), and ADLs/IADLs (Katz, Ford, Moskowitz, Jackson & Jaffe, 1963; Lawton & Brody, 1969). Caregiver well-being included depression (CES-D; Radloff, 1977), single-item physical health question, and positive aspects of caregiving (PAC; Lawton et al., 1989; Tarlow et al., 2004). Social support was based on satisfaction ratings and frequencies of social and formal care activities. Results: A significant model emerged for caregiver depression ($F_{8,634} = 30.53$, p<.001), revealing that satisfaction with social activities (β = -2.904, p<.001), satisfaction with social support (β = -.250, p<.001), frequency of formal care services (β = .283, p=.013), and care-recipient behavioral problems (β = .089, p=.023) were significant predictors of caregiver depression. Significant models also emerged for caregiver physical health ($F_{8,634} = 14.24$, p<.001) and positive aspects of caregiving ($F_{8,634} = 9.79$, p<.001). Multivariate regression analysis revealed that frequency of social activities was the only significant predictor of caregiver health (β = -.509, p<.001) and that satisfaction with social activities (β = .268, p<.001), satisfaction with social support (β = .202, p=.001), and patient cognitive impairment (β = -.015, p=.012) were significant predictors of positive aspects of caregiving. Conclusion: Caregivers' perception of support received, not just the amount received, plays an important role in their well-being.

### CORRELATIONS BETWEEN INDICATORS OF CAREGIVING-RELATED STRESS AND STRESS BIOMARKERS IN OLDER CAREGIVERS

S.O. Stuver, L. Fredman, C. Mezzacappa, *Epidemiology, Boston University School of Public Health, Boston, Massachusetts*

Chronic stress may lead to dysregulation of homeostatic systems and immune function. As evidence, caregivers have poorer neuroendocrine and immune profiles than non-caregivers in many studies. However, few studies have investigated whether caregiving stress measures are associated with these biomarkers. In a cohort study of elderly caregivers of persons with Alzheimer's or Parkinson's Disease in the Boston metropolitan area, we evaluated the correlation of the Sum of Care Recipient's Problem Behaviors and Reaction to Care Recipient's Problem Behaviors scales from the Revised Memory and Problem Behavior-Checklist (RMPBC) and the Caregiving-related Stress scale from the standard 14-item ADL/IADL scale with the stress biomarkers interleukin-6 [IL-6], dehydroepiandrosterone-sulfate [DHEA-S], cortisol, and epinephrine. The mean age of the 51 caregivers studied was 71.6, with 41% being female and 92% being white. They had mean scores of 9.6 (std, ±4.1) for RMPBC Sum of Care Recipient's Problem Behaviors, 12.4 (±9.9) for RMPBC Reaction to Care Recipient's Problem Behaviors, and 5.3 (±4.8) for Caregiving-related Stress. As anticipated, lower levels of DHEAS were correlated with higher Caregiving-related Stress (Spearman correlation, r=-0.216; p=0.23), which was stronger for dealing with physically difficult caregiving tasks (r=-0.296; p=0.09) than for emotionally difficult caregiving tasks (r=-0.158; p=0.38). In addition, lower levels of epinephrine were correlated increased distress due to Care Recipient's Problem Behaviors (r=-0.225; p=0.21). Neither IL-6 nor cortisol was significantly correlated with any of the indicators of stress related to caregiving. In summary, caregiving-related stress was associated with disruptions in selected neuroendocrine stress biomarkers in this older population of community-dwelling caregivers.

### UNDERSTANDING DISPARITIES AMONG HISPANIC AND WHITE NON-HISPANIC CAREGIVERS

N.J. Karlin[1], J. Weil[1], S. Collins[1], M. Adams[2], C. Fruhauf[3], *1. School of Psychological Sciences, University of Northern Colorado, Greeley, Colorado, 2. Weber State University, Ogden, Utah, 3. Colorado State University, Fort Collins, Colorado*

The focus of this study was concerned with understanding the differences between white and Hispanic familial caregivers providing care to a family member with Alzheimer's disease and related disorders (ADRD). Particular attention was paid to Hispanic caregivers since less is known about changes in caregiving patterns among this group in northern Colorado – where Hispanics make-up about one-third of the county population. Data suggests Hispanic care providers report both satisfaction and burden. Hispanic caregivers in this study were experiencing increased financial strain as a result of being a caregiver, had received help from others for a shorter duration of time, and had been in the caregiving role longer than their non-Hispanic counterparts. Participants indicated a desire to learn additional skills, gain knowledge, and to receive more support. With current trends of demographic changes and cultural inversion it is crucial to more fully understand the changing role and needs of Hispanic familial caregivers.

### MEDICATION REGIMEN FOR DEMENTIA IN CHINESE AMERICAN CAREGIVERS

Y. Chang[1,2], L. Wray[2], P. Chang[3], *1. The State University of New York, University at Buffalo, School of Nursing, Buffalo, New York, 2. VA Western New York Health System Center for Integrated Healthcare, Buffalo, New York, 3. Alzheimer's Association Northern California & Northern Nevada, Mountain View, California*

Background: More than 90% of Chinese American immigrants used numerous traditional Chinese herbal medicines to treat their disease symptoms. They may also combine some over-the-counter medications and prescribed medications without communicating with their health care providers. The drug-remedy interactions may pose potential risks to their health. Thus, there is a need to understand the scope of multiple medication regimens in Chinese American families for cognitive impairment symptoms. Purpose: This ongoing study aims to describe medication regimens for cognitive impairment among Chinese American caregivers of people with dementia and to examine the association between cultural beliefs about dementia and medication use. Method: This study is a cross-sectional design. Participants are recruited from Adult Day Health Center in San Jose and Chinese Outreach program in Alzheimer's Association Northern California and Northern Nevada chapter. Measures include the Cultural Beliefs about Dementia, the Medication Use Questionnaire, and a demographic questionnaire. Descriptive statistics and Pearson's correlation will be utilized for analysis. Results: We expect that a total of 60 family caregivers will participate in this study. Preliminary findings indicate 50% of participants used multiple medication regimens for treating dementia. We hypothesize a moderate correlation between cultural beliefs about dementia and mixed medication use. Conclusion: The findings will extend our understanding of mixed use of medications for dementia among Chinese American Caregivers. Also, our findings will indicate a need to develop culturally appropriate educational interventions to promote better communication between Chinese American older adults, their families, and health care providers regarding medication use in dementia treatment.

### CHALLENGES IN RECRUITING FAMILY CAREGIVERS TO A CLINICAL TRIAL ON MBSR FOR STRESS REDUCTION

R.R. Whitebird[1], M. Kreitzer[2], B. Lewis[2], A.L. Crain[1], L.R. Hanson[3,1], C.J. Enstad[1], *1. HealthPartners Research Foundation, Minneapolis, Minnesota, 2. University of Minnesota, Minneapolis, Minnesota, 3. Alzheimer's Research Center, Regions Hospital, St. Paul, Minnesota*

The Balance Study is a randomized controlled pilot study examining the effect of a mindfulness-based stress reduction intervention vs. a community caregiver education and support program on stress reduction. Participants were self-identified as caregiving for a family member with dementia. Outcome variables included both psychological and physiological (biomarker) data. We identified challenges in study recruitment and innovative efforts were required to recruit participants. Strategies included outreach within a large health plan and to community and social service organizations, print articles, paid advertising, and word of mouth. We received 256 calls about the study, of these 141 (56%) expressed interest and 112 were eligible for participation; 78 (70%) of those eligible consented with 72 completing the study. The challenges to recruitment we identified were: 1) family caregivers are a self-identified group who do not identify with the descriptor of "caregiver" and thus do not identify with a specific group/ venue that can be used for outreach; 2) cultural issues deeply influence how they see this role, their responsibilities, and define help-seeking behavior; 3) caregivers are heavily burdened by their caregiving duties and do not seek help until they are overwhelmed by stress; 4) they require help in addressing respite care issues; and 5) commuting requirements and time of day are critical to study participation. By addressing these challenges and giving significant focus to study retention, including regular contact during the intervention and follow-up phases, the study was successful in meeting our recruitment goal with 92% of those consenting completing the study.

## SESSION 1010 (POSTER)

## FUNCTION AND FALLING

### RISK FACTORS OF FALLS AND RECURRENT FALLS IN COMMUNITY DWELLING OLDER KOREAN WOMEN

Y. Lim, M. Sung, *Yonsei University, Wonju, Republic of Korea*

The purpose of the study was to determine which risk factors, biological, medical, behavioral, and home environmental factors, contribute to falls and recurrent falling in community dwelling older Korean women. The study population included 438 older women, aged 65 years and over. Risk factors included biological factor (old age), medical factor (chronic disease), behavioral factor (no physical activity), and home environmental factors (poor nightlight, non-slip bath mat, and doorsill). Risk indicators for accidental falls and recurrent falling were analyzed using logistic regression. Logistic regression analysis revealed that old age, chronic disease, poor nightlight, and doorsill were predictors of accidental falls, and no physical activity and non-slip bath mat were predictors of recurrent falling. The findings have implications for strategies and suggest the need to modify home environmental context in systematic and consistent ways and the need to maintain physical activities to prevent falls and recurrent falling.

### HEALTH RELATED QUALITY OF LIFE OF CHILEAN ELDERS AND ITS ASSOCIATION WITH FUNCTIONAL LIMITATIONS

L. Marques, C. Albala, H. Sánchez, A. Fuentes, F. Salas, X.D. Cea, *Public Health Nutrition Unit, . Institute of Nutrition and Food Technology (INTA), University of Chile, Santiago, Chile*

PURPOSE: To asses the quality of life of elder people with different degrees of Functional Limitations (FL) METHOD: Population based cross-sectional study conducted in Chile in 2009 in a representative sample of 4546 community-living subjects 60y and older (61.2% women).Severe FL was defined as having limitation in 1 ADL or/and 2 IADL, mild FL as having 3 mobility limitations and moderate FL as having any other combination. The Short-Form-36 Health Survey (SF-36) was applied to whole sample. Score of 8 subscales of SF-36 and summary measures Mental Component (MCS) and Physical Component (PCS) were calculated. Logistic regression analysis was used to estimate associations with MCS and PCS. RESULTS: The prevalence of disability was 28.6% (men 27.2%, women 29.5%). Women had lower scores than men after adjusting for age and FL. Subjects with severe FL had significantly lower mean scores than moderate and mild FL in all SF-36 domains and in PCS (35.8, 40.6, 43.0, respectively; $p<0.0001$) and MCS (35.8, 48.2, 48.4, respectively; $p<0.0001$). Logistic regression analysis showed the strongest association of poorer scores of PCS (p25) with levels of FL (mild OR=4.7; 95%CI 4.42-7.26, moderate OR=8.6; 95%CI 6.41-11.51, severe OR=26.7; 95%CI 16.82-42.27), being women (OR=1.7; 95%CI 1.45-2.06), low educational level (OR=1.42; 95%CI 1.16-1.73) and no association with age. The same associations were observed for low score in MCS (p25) except for an inverse association with age (OR=0.97; 95%CI 0.96-0.98) CONCLUSIONS: These results shows the significant impact of Functional limitations on quality of life in the elderly evincing socioeconomic and gender differentials. Funded by Fondecyt Grant 1080589, Chilean National Service for the elderly and Spanish Agency for International Cooperation

### POVERTY AND DISABILITY TRANSITIONS: IMPACT ON SOCIAL PARTICIPATION AND ISOLATION

M.J. Penning[1], S.P. Clouston[2], Z. Wu[1], M. Brackley[1], *1. University of Victoria, Victoria, British Columbia, Canada, 2. University of McGill, Montreal, Quebec, Canada*

Recent research has focused on the impact of life course transitions on a variety of outcomes. In particular, studies have addressed the impact of poverty transitions on various health and disability outcomes, with some attention also given to the impact of disability transitions on other relevant outcomes, such as social isolation and participation. However, less attention has been given to intersecting transitions. As a result, little is known regarding the implications of becoming disabled when one has never been poor versus becoming disabled when one has always been poor. We know even less about the differential impacts when experiencing both transitions at once: becoming poor while becoming disabled. This is particularly evident in the Canadian context. This poster reports the results of analyses conducted to address the impact of both poverty and disability transitions on social isolation and participation experienced at different stages of the life course. Data are drawn from the National Population Health Survey (NPHS), Household Component, longitudinal data files (Cycles 1 to 7, 1994/95 to 2006/07). These include data obtained from a nationally representative sample of 17,276 respondents aged 12 and over first interviewed in 1994/95. Findings suggest that disability is worse for those who are always poor than those who are always rich, but that the transition is particularly difficult for those who experience transitions simultaneously. Research and policy implications are discussed.

### A COMMUNITY-BASED FALL PREVENTION INTERVENTION THAT MAY IMPACT FEAR OF FALLING AND LEISURE FOR OLDER ADULTS

C.M. Headley[1], L.L. Payne[2], C. Katzenmeyer[3], *1. Exercise & Sport Science, Judson University, Elgin, Illinois, 2. University of Illinois, Champaign, Illinois, 3. Metropolitan State College, Denver, Colorado*

Multi-factorial, multidimensional community-based fall prevention programs have been shown to have a decrease in the risk of falls in older adults and can have a greater reach within a community. The purpose of this study was to examine the effects and influence of N'Balance, a community-based fall prevention intervention for older adults, and better understand fear of falling and its implications for leisure among older adults. N'Balance is a multi-factorial, multidimensional intervention focusing on challenging and improving the sensory systems. This was a community-based intervention trial with a control group using two sites. A two-way (group x time) ANOVA was used to examine differences in the dependent variables within each group over time (from pre- to post-test) and between groups (intervention vs. control). Results of pre- and post-test assessments indicated that N'Balance was associated with improved balance (.00) and the fear of falling (.04). Leisure self-efficacy approached significance (.06) as a result of participation in N'Balance. Overall, the results indicated that N'Balance is a promising intervention program that seems to have physical and psychosocial benefits for older adults.

### INFORMATION PROCESSING AND FEAR OF FALLING IN OLDER JAPANESE ADULTS

F. Togo, A. Ohnishi, K. Ishimatsu, *National Institute of Occupational Safety and Health, Japan, Kawasaki, Japan*

The present study examined the associations between information processing and fear of falling in 28 male volunteers, aged 60-69 years. Reaction times (RT) for simple RT and flanker tasks were collected. For the simple RT task, participants pressed a key as quickly as possible once the stimulus appeared on the screen. For the flanker task, stimuli consisted of a row of 5 items with the third (central) item as either a leftward or rightward pointing arrow. Participants focused on the central target and pressed one key when the central target pointed to the left or a different key when it pointed to the right. The two items (flankers) on either side of the central target were either horizontal lines (neutral condition) or arrows. The congruent and incongruent flanker conditions consisted of flanking arrows pointing in the same and opposite direction as the central target, respectively.. Participants completed 20 trials of the simple RT task and 96 trials of the flanker task. Information processing speed was calculated by subtracting the median simple RT (i.e., reflecting motor response time) from the median RT of each flanker condition. Fear of falling was assessed by the Modified Fall Efficacy Scale. Simple RT did not correlate with the level of fear of falling. Information processing speed did not correlate with the level of fear of falling for congruent or incongruent conditions, but correlated significantly for the neutral condition. These results indicate that impaired information processing might correlate with falls in the elderly.

### CO-MORBIDITIES AND PERCEIVED FUNCTIONAL ABILITY IN OLDER ADULTS

R.J. Gretebeck[1], K. Gretebeck[2], *1. Kinesioogy, Health and Sport Studies, Wayne State University, Detroit, Michigan, 2. University of Michigan, Ann Arbor, Michigan*

Regular physical activity (PA) is beneficial for older adults although is often affected by chronic diseases and physical impairments. The objective of this investigation was to examine how co-morbidities impact perceived functional ability in older adults. Questionnaires were mailed to retired non-faculty staff members from a large university with questions on demographics, functional ability, and health. Participants included 1,091 (53.8% female) older adults (65-98 years, M age=75.47+6.67) Subjects were asked if they had been diagnosed with any of the following chronic conditions: Arthritis, heart trouble, high blood pressure, circulation trouble, diabetes, cancer, stroke, or asthma, or no medical problems. Subjects where categorized as having 0, 1, 2, or three or more co-morbidities (9.4, 32.1, 26.7, and 21.3 % of the subjects respectively), and were compared using ANOVA on different aspects of perceived functional ability. There was no significant difference between 0 and 1 condition on functional ability measures of walking, stair climbing, light house work, heavy housework, and lifting 10 pounds. However, for these same variables, subjects with 2 conditions had significantly lower functional scores than 0 and 1, and subjects with three or more chronic conditions had significantly lower scores than subjects with 0, 1, or 2 conditions. These results suggest that 1 condition appears to be well tolerated, but as co-morbidities increase functional ability declines.

### DO MOBILITY ASSISTIVE DEVICES PREVENT HOSPITALIZATIONS FOR ACCIDENTAL FALLS OR INJURIES AMONG OLDER ADULTS?

K.A. Pressler, L.P. Sands, K. Ferraro, *Purdue University, West Lafayette, Indiana*

Mobility assistive devices (e.g. walkers, canes, and wheelchairs) are well-known mechanisms for fall prevention. However, to our knowledge, no one has examined whether mobility assistive devices do indeed prevent falls using a nationally representative sample of disabled older adults. Methods: Three waves of the National Long Term Care Survey (NLTCS) with samples exceeding 5,000 cases at each wave were linked to Medicare Inpatient Hospitalization Claims from 1994-2005. A series of logistic regressions were performed where hospitalizations that resulted from an injury or fall in 1995, 2000, and 2005 were the dependent variables. Respondents' self-report of mobility device use was drawn from the 1994, 1999, and 2004 NLTCS surveys, along with lower body Nagi disability level, age, gender, race, and whether the respondent received personal care performing ADLs. Finally, whether respondents experienced a hospitalization in the previous year was also controlled for. Results: Fall and injury risk was highest among older adults who were hospitalized in the previous year, were older, white, had greater lower body disability, and received ADL personal care. Mobility assistive device use in 1994, 1999, and 2004 was not a significant predictor of a subsequent hospitalization resulting from a fall or injury. Respondents who experienced a hospitalization within the past year were 59% (p<.01) more likely in 1994 and 119% (p<.001) more likely in 2004 than those who were not hospitalized to experience a fall/injury hospitalization that following year. Conclusion: The use of mobility assistive devices among older adults has no effect on subsequent fall/injury hospitalization risk.

### FEAR OF FALLING IN COGNITIVELY IMPAIRED OLDER ADULTS: PSYCHOMETRIC PROPERTIES OF THE FES-I

G. Zijlstra[1], G.I. Kempen[1], M. Schwenk[2], L. Yardley[3], N. Beyer[4], C. Todd[5], K.A. Hauer[2], *1. Maastricht University, CAPHRI - School for Public Health and Primary Care, Maastricht, Netherlands, 2. Bethanien-Krankenhaus / Geriatric centre at the University of Heidelberg, Heidelberg, Germany, 3. School of Psychology, University of Southampton, Southampton, United Kingdom, 4. Institute of Sports Medicine, Bispebjerg Hospital, Copenhagen, Copenhagen, Denmark, 5. School of Nursing, Midwifery and Social Work, University of Manchester, Manchester, United Kingdom*

Older adults with cognitive impairment are at high risk of falling and fall-related consequences. To evaluate fall prevention strategies in this population measures with good psychometric properties are needed. The aim of this study was to determine the psychometric properties of two scales that assess concerns about falling: the 16-item Falls Efficacy Scale International (FES-I) and the 7-item Short FES-I. Ceiling and floor effects, internal consistency reliability, and construct and discriminant validity were studied in cross-sectional data from 157 older adults with cognitive impairment. Ceiling effects, i.e. minimum scores indicating no concerns about falling, were more prevalent in the Short FES-I than the FES-I (14.0% vs. 3.2%). No floor effects were detected. Cronbach's alpha's for the FES-I and Short FES-I were .91 and .82, respectively. Non-parametric testing showed significant differences (p<.05) in mean scores of the scales according to sex, dizziness, falls history, ADL, timed-up-and-go, and fear of falling, indicating construct validity. Effect sizes (ES) confirmed good discriminant validity. The results of this study indicate the good psychometric properties of the FES-I and Short FES-I in older adults with cognitive impairment. The application of the 16-item FES-I may be desirable to prevent or minimise ceiling effects.

## SESSION 1015 (SYMPOSIUM)

### HEALTH MANAGEMENT, BEREAVEMENT SUPPORT, AND LATE LIFE AND DEATH PLANNING FOR PERSONS WITH INTELLECTUAL DISABILITIES

Chair: *J. Gray-Stanley, Public Health & Health Education, Northern Illinois University, Dekalb, Illinois*

Co-Chair: *E.A. Perkins, University of South Florida, Tampa, Florida*

This is the official symposium for the Formal Interest Group on Developmental Disabilities. Due to increased longevity in adults with intellectual disabilities (ID), health management, bereavement counseling, and planning for late life and death has become increasingly important. This symposium highlights research examining these issues. Bowers, Webber, and Bigby examined the management of health conditions of older adults with ID who live in group homes. They found that treatment was limited for several reasons, including a lack of information about the health conditions, practical considerations, and protecting residents from being moved to higher levels of care. Clute analyzed data from bereavement counselors working with adults with ID and specifically examined professional roles and responsibilities that social workers and counselors must adopt in serving bereaved individuals with ID. It was found that professional content should be delivered with a sense of empathy and compassion. Williams examined families' planning for late-life care of individuals with ID, at a time when parents would not be able to help with instrumental care, advocacy, or oversight roles. They found that conversations about death were more likely to occur between parents and their children with ID, rather than with their children without disabilities. Different types of late-life and death planning could be related to early developmental trajectories and family structural patterns. All presentations emphasize the necessity of both research and education for staff, families, and clients with respect to health management, bereavement support, and late-life and death planning for persons with ID.

### UNDERSTANDING AND MANAGING HEALTH CONDITIONS IN GROUP HOME RESIDENTS WITH INTELLECTUAL DISABILITY

B.J. Bowers[1], R. Webber[3], C. Bigby[2], *1. Nursing, University of Wisconsin-Madison, Madison, Wisconsin, 2. La Trobe University, Melbourne, Victoria, Australia, 3. Australian Catholic University, Melbourne, Victoria, Australia*

Life expectancy of people with intellectual disability has increased dramatically over the past few decades. As a result, people with intellectual disability are living long enough to develop the health conditions that are common among older adults. As many of these older adults are living in group homes, it is the group home staff who must often respond to age related health changes and their consequences. This paper reports on a longitudinal grounded theory study of 15 group homes and 17 residents with intellectual disability over age 50 in Victoria, Australia. Findings suggest that staff often delay seeking treatment for health conditions for several reasons; 1) protecting the resident from being moved to aged care, 2) assuming symptoms are related to prior conditions, 3) assuming that age related changes are irreversible and, 3) logistical challenges. Implications for staff development and provider education are discussed.

### FAMILY STRUCTURE, DEVELOPMENTAL TRAJECTORIES, AND PLANNING FOR LATE-LIFE AND DEATH IN FAMILIES OF INDIVIDUALS WITH INTELLECTUAL DISABILITIES

A.A. Williams, *University of Colorado at Colorado Springs, Colorado Springs, Colorado*

In a qualitative study involving 33 phenomenological interviews, family members of individuals with intellectual disabilities (ID) revealed three degrees of planning for late-life care of individuals with ID in anticipation of a time when parents would no longer be able to assist with instrumental care, advocacy, or oversight roles for their sons and daughters with ID. When talking about death, family members voiced hopes that those with ID would not suffer with illnesses during late life and that they would not be distressed or afraid of death. In many families, conversations about death had occurred between parents and their sons and daughters with ID, while conversations about illness and death were avoided among parents and their other sons and daughters. Early developmental trajectories and family structural patterns influenced family members' views of late-life care and preparation for death of both parents and family members with ID.

### ACCOMPANYING: MENTORING AND PREPARING BEREAVEMENT COUNSELORS TO BE WITH INDIVIDUALS WITH ID ON THEIR GRIEF JOURNEY

M. Clute, *1. Social Work, Eastern Washington University, Cheney, Washington, 2. Hospice of Spokane, Spokane, Washington*

Qualitative data from interviews with bereavement counselors working with adults with intellectual disabilities (ID) is further analyzed. The original grounded theory analysis included strategies for supporting successful movement through grief for clients with ID. The subsequent focus of the data analysis is on professional roles and responsibilities of social workers and counselors working with bereaved individuals with ID. Finer analysis and focused attention is on data gathered in answer to the following research questions: What has been helpful to you in preparing yourself to work with adults with cognitive disabilities? What would you recommend for other counselors to increase their expertise with this population? It is imperative that MSW students, as well as current practitioners be expected to provide empathetic and competent services to our aging individuals with ID and their families. The data offers not only hope, but suggestions on how to proceed.

## SESSION 1020 (PAPER)

### LEISURE ACTIVITIES FOR PERSONS WITH DEMENTIA

### THE ROLE OF LEISURE WITHIN THE DEMENTIA CONTEXT

R. Genoe[1], S. Dupuis[2], *1. Faculty of Kinesiology and Health Studies, University of Regina, Regina, Saskatchewan, Canada, 2. University of Waterloo, Waterloo, Ontario, Canada*

While our understanding of the subjective experience of dementia is growing, there is limited information on the role of leisure in the lives of persons living with early stage memory loss. This hermeneutic phenomenological study explored the meaning and experience of leisure within the dementia context. Community-dwelling persons living with early stage dementia engaged in four interviews and participant observation over several months to explore what leisure means to them. In addition, using the method of photovoice, participants took photos of subjects, objects, and spaces that were meaningful for their leisure. These photos were used to guide our discussion around leisure and dementia. Data, including interview transcripts, observation field notes, and photos were analyzed in a manner consistent with phenomenology. Findings revealed that participants experienced leisure within a complex paradox of challenge and hope. They struggled with the changes resulting from dementia, experiencing muddled thinking, fluctuating abilities, draining energy, frightening awareness, and disquieting emotions. However, participants counteracted these changes by tackling life with dementia. They were able to remain positive about their situations by reconciling life as it is, battling through by being proactive, living in relationships, being optimistic, and prolonging engagement in meaningful activity. Participants' stories and photos revealed that leisure played a vital role in coping with the changes they experienced as a result of dementia

### EVERYDAY, ENJOYABLE ACTIVITIES OF PERSONS WITH DEMENTIA

H. Menne, J. Johnson, C.J. Whitlatch, S. Schwartz, *Margaret Blenkner Research Institute, Benjamin Rose Institute, Cleveland, Ohio*

Research on persons with dementia has highlighted the importance of personhood and encouraged the continued engagement of persons with dementia in activities that they find enjoyable. Declines in cognitive ability may require that enjoyable activities be modified (e.g., books on tape rather than reading), or that new activities be introduced. Before practitioners and families can modify or introduce new activities, it is necessary to understand what activities persons with dementia are currently enjoying. As part of a longitudinal study on the stress and well-being of caregiving dyads, 267 persons with dementia completed up to 5 in-person interviews. During each interview, persons with dementia were asked: "What kinds of activities do you like to do now?" An iterative coding process was used to categorize the 1,984 responses to this question. From the first wave of data collection (n = 885 responses), over 50% of the responses were in the categories of: Socialize (19.77%), TV/Music/Radio (13.9%), Exercise/Recreation (11.19%), and Cognitive Stimulation (10.28%). Interestingly, the activities reported by persons with dementia are the same as activities reported in previous studies of older adults' leisure activities (Kelly et al., 1986; Verbrugge et al., 1996). Family caregivers and practitioners can ease their burden of providing care as well as enhance the personhood of persons living with dementia by: a) recognizing the everyday activities that persons with dementia already enjoy; b) adapting activities to be at the appropriate level for the person with dementia, and c) engaging persons with dementia in decisions about their daily activities.

### BENEFITS AND BARRIERS OF COMPUTER ACTIVITIES AND GAMES FOR PERSONS WITH DEMENTIA

S.H. Tak, C. Beck, *University of Arkansas for Medical Sciences, Little Rock, Arkansas*

The study examined the feasibility of providing a 12-week computer activity program for cognitively impaired elders in nursing homes. Fourteen residents with dementia completed the computer activity program. Observation data were collected using 462 observational logs of computer sessions. The mean age of participants was 82 years. Their cognitive impairment ranged from severe to mild dementia with a mean Mini Mental State Exam score of 14.9. On average, participants had 33 sessions and spent 936.5 minutes in the program. Sessions lasted 28 minutes on average. Prior to the program, participants neither had previous computer experience nor provided a computer training. All of them required an RA's assistance initially but the level of needed assistance become varied by the end of the program, ranging from simple watching, clicking, to performing simple-to-complicated activities. Participants with mild and moderate dementia preferred playing a cognitively challenging game such as solitaire, while participants with severe dementia tended to prefer simple games. The participants sang along with the music and talked about the pictures in the slideshows. The intensity of participation was high during sessions (mean score of 2.2 out of 3.0). The barriers that influenced participants' levels of engagement in CAG included cognition and physical health, technological problems, computer literacy and interests, and environmental factors. It is important to take into account different levels of cognitive and physical functioning and different interests and use adaptive accessories to increase participation in CAG and satisfaction with these activities.

## SESSION 1025 (PAPER)

## MEXICAN AMERICANS' HEALTH AND WELL-BEING

### SLEEP AND MORTALITY AMONG OLDER MEXICAN AMERICANS

B. Howrey, M. Peek, K. Ottenbacher, M. Raji, *UTMB, Galveston, Texas*

Poor sleep quality has been linked to many negative health outcomes: lower quality of life, poor cognition, falls, and premature death. Yet, little data exist on how poor sleep affects mental and physical health of older adults, especially older ethnic minorities. Older Mexican Americans, in particular, have increased rates of certain comorbidities that are linked to poor sleep quality, such as diabetes. To address this gap in the literature, we examine the effects of sleep problems on mortality over a 12-year period in a population based sample of older Mexican Americans, a fast growing segment of US population. Using five waves of data (1994-2006) on older Mexican Americans (Hispanic Established Population for the Epidemiologic Study of the Elderly – HEPESE) (n = 2,439), we use cox proportional hazard models (STATA 10) to model the risk of death as a function of chronic sleep problems. The results from the unadjusted Kaplan-Meier estimates show that increased chronicity of sleep problems are associated with decreased survival (p<.001). In addition, the cox models showed that having any sleeping problems during the last month is associated with increased risk of mortality (HR=1.20, 95% CI 1.05, 1.36) in models adjusted for age, gender, socioeconomic status, and body mass index. In conclusion, increased problems with sleeping are related to an increased risk of mortality in an older Mexican American sample. These findings have important clinical and public health implications. Sleep problems are under diagnosed among older adults and warrant attention as a risk factor for poor health outcomes.

### STABILITY OF SELF-RATINGS OF HEALTH: DIFFERENCES IN HEALTH OUTCOMES FOR OLDER MEXICAN AMERICANS

M.C. Sutton, G.I. Caskie, K.E. Gunnet-Shoval, *Education, Lehigh University, Bethlehem, Pennsylvania*

Self-rated health (SRH) has been studied as a predictor of physical and mental health outcomes; however, few studies have examined stability of SRH in older Mexican Americans. Data from the Hispanic EPESE were utilized to determine physical (ADL and IADL limitations, co-morbid health conditions) and psychological health (depression, cognition, life satisfaction) differences at an 11-year follow-up assessment, based on the stability/change of self-ratings of health over an 11-year period. The sample (n=1,118) included Mexican Americans aged 70.87 years on average (range=65-92), with a mean of 4.95 years of education (range=0-17). One-way MANOVAs indicated significant differences between SRH stability groups (declined n=402, stable n=478, improved n=238) in ADLs and IADLs as well as depression and life satisfaction (all ps<.001). Age group (65-69, 70-74, 75+) and sex were then examined as potential moderators of the relationship of SRH stability to health outcomes. Significant interactions with SRH stability with age group only were found for ADLs and IADLs (p=.035). Even with age group and sex controlled, all four significant main effects for SRH stability were maintained. Post hoc comparisons indicated that, at the 11-year follow-up, individuals whose SRH declined endorsed significantly greater ADL and IADL limitations and greater depression than individuals whose SRH improved or remained stable; also, those whose SRH improved had lower depression and greater life satisfaction than those whose SRH was stable. Thus, changes in self-ratings of health – declines in particular – may be an important factor in understanding differences in later-life health outcomes for Mexican American elders.

### ACCULTURATION AND SELF-ESTEEM FOR OLDER MEXICAN AMERICANS: DIFFERENCES BY ETHNIC SELF-IDENTIFICATION

G.I. Caskie, B.L. Perkins, C. DeBlaere, *Education and Human Services, Lehigh University, Bethlehem, Pennsylvania*

Although previous studies have found that self-esteem is positively enhanced by increased levels of acculturation among Mexican-American older adults, little research has explored these variables and the relationship between them as a function of ethnic self-identification. Therefore, the present study explores: first, the ways in which Mexican-American older adults differ across ethnic self-identification groups in terms of demographic characteristics and acculturation, and second, how the relationships of language acculturation and biculturality to self esteem differ across ethnic self-identification groups. Secondary analysis was conducted using the baseline Hispanic EPESE data that were available for a sample of 2689 Mexican Americans (1119 males, 1570 females) aged 65 to 99 years. Individuals self-identifying as Mexican (n=1233) had significantly less education (p<.001), less language acculturation, and reported less language biculturality than those self-identifying as Mexican-American (n=1210) or American (n=246) and were less likely to have been born in the US (p<.001), but did not differ in age or by gender. Although Mexican-Americans had significantly less education and language acculturation than Americans, no differences were observed in language biculturality. Both language acculturation and biculturality were significantly related to self-esteem in the total sample (p<.001); however, these relationships differed by ethnic self-identification group. Greater language acculturation was significantly related to higher self-esteem for the Mexican (p<.01) and Mexican-American groups (p<.001); greater language biculturality was significantly related to higher self-esteem only for the Mexican group (p<.05). Thus, how older adults of Mexican heritage choose to identify their ethnic group influences the relationship between acculturation and self-esteem.

### ALLOSTATIC LOAD IN TEXAS CITY: EXPLORING AGE- AND RACE/ETHNICITY-BASED PATTERNS

C. Mair[1], M. Cutchin[2], M. Peek[3], *1. North Carolina State University, Raleigh, North Carolina, 2. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, 3. The University of Texas Medical Branch, Galveston, Texas*

Allostatic load is a composite physiological measure of the body's ability to adjust to stressors, with higher allostatic load indicating a lower ability to adjust. Theories of allostatic load suggest that racial/ethnic minorities, older adults, and individuals in particularly stressful contexts are likely to have elevated allostatic load. Although few studies have empirically examined race/ethnic differences in allostatic load, prior evidence finds that blacks, U.S.-born Mexican-Americans, and older adults score higher on allostatic load than whites and younger individuals. Foreign-born Mexicans tend to have lower allostatic load compared U.S.-born Mexican Americans. We analyzed data from the Texas City Stress and Health Study, a survey of individuals residing near a cluster of oil refineries (N=1300, aged 25-90 years). Using bivariate analyses and OLS regression of cross-sectional data, we examined age patterns in allostatic load according to racial/ethnic group as well as potential stressors and buffers of allostatic load. Bivariate analyses indicated that non-Hispanic blacks had a higher mean allostatic load compared to non-Hispanic whites (p=0.04) while recent immigrants of Mexican origin exhibited lower allostatic load than non-Hispanic whites (p=0.02) and non-Hispanic blacks (p<0.001). Age showed a curvilinear association with allostatic load (lower allostatic load in youngest and oldest groups), but the association differed by race/ethnic group. Effects of contextual stressors and social support also differed by race/ethnic group. We discuss the implications of these findings vis-à-vis the growing literature on health risk and allostatic load by highlighting the importance of investigating age- and race/ethnic-based patterns of this physiological measure.

## SESSION 1030 (POSTER)

## SEXUALITY AND SEXUAL BEHAVIOR

### THE ASSOCIATION OF SEXUAL TOUCHING WITH SEXUAL PROBLEMS AMONG OLDER ADULTS IN THE UNITED STATES

A. Galinsky, *University of Chicago, Chicago, Illinois*

Theoretical models of human sexual response and evidence from qualitative studies suggest that engaging in intimacy-enhancing, non-penetrative sexual behavior can affect the sexual functioning of both men and women. This study tests the hypothesis that frequency of sexual touching is negatively associated with the probability of experiencing the most common sexual problems. We use data from the 2005-2006 National Social Life Health and Aging Project. Our sample consists of the (N=1,433) respondents ages 57-85 who had sex in the past year. We use logistic regression to model the occurrence of each sexual problem, separately by gender, as a function of sexual touching, controlling for age, race-ethnicity, and health status, and adjusting for survey design. Men who usually engaged in sexual touching had 2.3 (95% CI 1.3, 3.9) times the odds of having trouble getting or maintaining an erection, and 2.1 (95% CI 1.2, 3.7) times the odds of feeling anxious about their ability to perform sexually, compared to men who always engaged in sexual touching. Similar or greater differences were found between men who sometimes, rarely, or never engaged in sexual touching, compared to those who always did, in the odds of experiencing those problems, as well as in the odds of not finding sex pleasurable, being unable to climax, and lacking interest in sex. Very similar results were also found for women. When sexual problems are defined as symptoms about which the respondent is "bothered" (a DSM-IV-TR criteria for diagnosing many sexual disorders), the association with sexual touching persists.

### OLDER MEN'S ATTITUDES ABOUT SEXUAL PERFORMANCE: THE EFFECTS OF ERECTILE DIFFICULTIES

K. Barnes, E.H. Thompson, *Sociology & Anthropology, College of the Holy Cross, Worcester, Massachusetts*

Earlier gerontological research has examined mass media presentations of male sexuality and men's erectile difficulties, older men's sexual behavior, and in small qualitative studies men's experiences with erectile difficulties. But few studies have examined older men's attitudes about the importance of an erection and sexual performance, and no study has compared the attitudes of men with and without ED towards sexual performance/competency. This study was designed to investigate if middle-age and older men perceive an erection and sexual performance as intrinsic to masculinity, and if performance attitudes are effected by men's own erectile ability and competency. Using a community-based sample of mature men (N = 133; age 45-83; mean age: 60) from the New England area, difference in means test initially revealed that men with ED rate their sexual relationship as significantly less satisfying than men without ED, and they also perceive being able to have and maintain an erection significantly more central to masculinity than men without ED. However, regression analyses reveal that it was not the condition of having ED that was central to satisfaction with sexuality, it was confidence with keeping an erection; and, men's gender ideology was the key determinant of men's beliefs about importance of an erection for sexual performance/ competency. These findings demonstrate men with erectile difficulties differ more among themselves than they different from same age men without ED. Clinicians working with men with ED should not assume they approach sexuality any different than men without ED.

### LESBIAN, GAY, BISEXUAL, TRANSGENDER (LGBT) ELDERS IN SENIOR HOUSING: NEED FOR INCLUSION

A. Frankowski, R. Perez, S. Goldman, E. Roth, R. Rubinstein, *UMBC, Baltimore, Maryland*

Long considered underserved and understudied, lesbian, gay, bisexual, and transgender (LGBT) older adults are often ignored, dismissed, and/or discriminated against in senior housing, leaving many feeling isolated and closeted. With the number of LGBT individuals over the age of 60 in the United States estimated to be between 1.75 and 4 million, research on this "invisible" cohort is crucial. To understand the unique cultural needs of this underrepresented population, we examine: 1) administrator, staff, family, and resident values and beliefs toward LGBT elders; 2) the barriers that exist in the culture of senior housing; and 3) the social and medical needs of LGBT elders to ensure their inclusion in residential settings. Two sources of data inform this work. We analyzed over 1500 fieldnotes and ethnographic interviews collected at eighteen senior housing settings for three NIA-funded studies. Sites include one active adult neighborhood, one continuing care retirement community, two independent living residences, and fourteen assisted living settings. Second, we analyzed academic sources and policy reports on LGBT elders to ascertain how they are included by researchers and analysts. Our findings indicate that the health and social needs of LGBT elders in senior housing are not being adequately addressed. We identify problems and offer solutions to preserve LGBT elders' dignity and quality of life. This will inform policy and practice on how to include and care for LGBT elders in these settings.

### THE ASSOCIATION BETWEEN PHYSICAL HEALTH AND SEXUAL ACTIVITY: MEDIATING FACTORS FOR MARRIED OLDER ADULTS

L.A. Snyder, T.M. Cooney, *Human Development and Family Studies, University of Missouri, Columbia, Missouri*

Although research has explored the connection between physical health and sexual activity, factors that mediate this association have received limited attention. Further, rarely does research examine these associations for married older adults and by considering relational and spousal variables. To address these gaps in the literature, this study investigated how married older adults' sexual attitudes and relationship factors, and spouse's health influence the association between their own physical health and sexual activity with their spouse. We broadly define sexual activity to include physical intimacy beyond intercourse, as older adult couples may adapt their intimacy when negotiating issues related to aging or health. The study's sample included 1801 married older adults ages 57 to 85 who participated in the 2005-2006 National Social Life, Health, and Aging Project (NSHAP) conducted by NORC. We use structural equation modeling (SEM) to assess how physical health is linked to sexual activity and the mediating role of the following: values and beliefs about sexuality and sex; marital relationship quality and satisfaction, length of the marriage, rating of the spouse as a confidant; and the spouse's health. Statistical analyses also assess gender differences in mediators of the health-sexual activity connection and offer insight into what factors are related to engagement in marital sexual activity even when people are not in good health. Our findings demonstrate the presence of sexual activity in a marriage regardless of age and health, encouraging researchers and clinicians to consider how couples may adapt their sexual activity to accommodate health challenges.

### THE SEX TALK IN LATER LIFE: MARITAL STATUS AND COMFORT DISCUSSING SEXUALITY WITH A PHYSICIAN

S. Adams, *Case Western Reserve University, Cleveland, Ohio*

Sexuality is an important aspect of well-being in later life, but sexual issues are infrequently discussed between older patients and physicians. Furthermore, little is known about how marital status is related to variation in older adults' comfort discussing sexuality in clinical settings. This paper explores the influence of marital status on level of comfort discussing sexuality with a physician in a sample of non-institutionalized adults between the ages of 57 and 85 residing in the U.S. Results from ordered logistic regression models illustrate that married/partnered (OR = 0.52), widowed (OR = 0.57), and never married (OR = 0.35) respondents have significantly lower odds of reporting greater comfort discussing sexuality relative to divorced respondents. These findings remain robust even after controlling for other factors, including sexual activity and gender, demonstrating the unique influence that the institution of marriage has on the level of comfort discussing sexuality with a physician. Moreover, two non-mutually exclusive hypotheses emerge from these findings that can be explored in more detail through future research. First, older adults have been socialized to regard sexuality as a highly private matter only to be discussed in the context of the marital relationship, but divorce has a liberalizing effect on reticence over sexual-based conversations. Second, older adults who have divorced are more likely to be comfortable discussing sexuality outside of marriage. These results also suggest the presence of unmet sexual health needs associated with marriage, further emphasizing the importance of physicians overcoming any reluctance to discussing sexuality with older patients.

### INAPPROPRIATE SEXUALIZED BEHAVIOR IN THE OLDER DEMENTED PATIENT

N. Javier, K. Kelly, A.O. Troncales, *Medicine/Geriatrics, Brown University, Providence, Rhode Island*

CASE: SG is an 83 year old male with history of depression on medication who presented to the clinic for memory loss secondary to underlying dementia. He was subsequently started on a cholinesterase inhibitor. Six weeks later, his daughter reported that the patient had not been taking his medications. He had exhibited inappropriate sexualized behavior towards another daughter with whom he lives with and who in turn had four children ranging from 2 to 14 years old. The patient would ask his daughter to engage in sexual activity despite her protest. While naked, he would also go to his teenage grandson's room and chat with him. Social work was immediately involved. The two major concerns were managing the patient's hypersexual behavior and protecting the children from potential sexual abuse. The local child protection agency evaluated the situation and instituted a safety plan for the children. The patient who was followed up in the clinic showed remorse and acknowledged that he had no recollection of the matter. He agreed to comply with all his medications with the addition of a low dose antipsychotic. Over the next two weeks, his hypersexual behavior improved. DISCUSSION: Approximately 7% of demented patients exhibit hypersexuality. This is defined as a clinically significant level of desire to engage in sexual behavior manifesting as changes in an individual's sexual appetite, preferences, and capabilities. Management strategies include pharmacologic and nonpharmacologic interventions. Commonly used medications include serotonin-reuptake inhibitors, tricyclic antidepressants, antiandrogens, and antipsychotic agents. Non-pharmacologic treatment includes behavioral therapy, environmental manipulation, counseling, and education.

### SOCIAL SUPPORT AND SEXUAL INTEREST IN OLDER ADULTHOOD: A PROFILE FROM THE NATIONAL SOCIAL LIFE, HEALTH AND AGING PROJECT (NSHAP)

J.L. Griffith, *1. Mount Sinai School of Medicine, Department of Geriatrics and Palliative Medicine, New York, New York, 2. James J. Peters VA Medical Center, Geriatric Research Education and Clinical Center, Bronx, New York*

It is intuitive to believe that having an emotionally supportive partner could positively impact your sexual interest, but a nationally representative evaluation of this relationship has never been examined. Utilizing data from the 2005-2006 National Social Life, Health and Aging Project (NSHAP), a population-based study of community dwelling older North Americans ages 57 to 85, I develop a profile of the relationship between social support and sexual interest among older adults with respect to gender, relationship status and health status. Results suggest that among partnered older adults emotional social support is positively correlated with sexual interest. In addition, health is negatively correlated with sexual interest and women are more likely to lack sexual interest. It is important to note that sexual interest does not vary from the young old to oldest old. These findings suggest having an uncritical partner to open up to is important for older adults in feeling sexual interest. These findings highlight how older adults in relationships with positive emotional social support are more likely to show sexual interest. Life transitions, such as a partner becoming ill, can negatively impact sexual interest. I conclude by urging increased training to interdisciplinary healthcare professionals about the importance of sexuality in older adulthood.

### DIFFERENCES IN HEALTH AND HEALTH CARE: ADDRESSING DIVERSITY IN SEXUALITY AND AGING

N. Orel, C. Stelle, W. Watson, *Gerontology, Bowling Green State University, Bowling Green, Ohio*

The CDC reports that 24% of persons living with HIV/AIDS are over age 50, and people ages 50-64 account for 13% of new HIV diagnoses in the United States (2008). Despite the increasing number of older adults being diagnosed with HIV/AIDS, older adults, health care providers, and society at large continue to view this population as being at low risk for sexually transmitted diseases. Although an adequate sexual history should be part of any comprehensive assessment of the physical/psychosocial needs of older adults in order to provide appropriate health care, often, this is an uncomfortable task for health care professionals. This poster will provide a guide for assessing needs of older clients in the arena of sexual health. Drawing upon the work of Hays (1996), the acronym ADDRESSING will be used to discuss the cultural factors and personal attributes that influence sexuality and the importance of these factors and attributes in health and health care. ADDRESSING includes: Age, Degree of physical ability, Degree of cognitive ability, Religiosity, Ethnicity and race, Socioeconomic status, Sexual orientation, Individualistic life experiences, National origin, and Gender. Additionally, it is important to identify the "dominant discourse" of each of the personal attributes in order to foster an understanding of the diversity that exists in the expression of sexuality. To appropriately and adequately serve older clients, health care providers must seek to understand the client's perspective and how each of these areas of diversity bears on one's attitudes, experiences, and needs regarding sexuality and sexual health.

## SESSION 1035 (PAPER)

## SOCIAL INTERACTION

### GIVING SUPPORT AND MENTAL HEALTH IN OLDER ADULTS: A NOVEL ASPECT OF SOCIAL INTERACTIONS

M. Smith, A. Fiske, *West Virginia University, Morgantown, West Virginia*

Receiving support has been studied extensively, while giving support to others is an overlooked component of social interactions that may have potential to promote better mental health in older adults. Giving support can include formal support giving through volunteer work or informal support giving to family, friends, or neighbors. It is unclear how giving support may relate to positive (well-being, life-satisfaction, positive affect, purpose in life, happiness, self-efficacy, and self-esteem) and negative (depression, negative affect, distress, and loneliness) mental health outcomes. This critical review of twenty-one studies examined the relation between both formal and informal support giving and mental health outcomes in late life. There is consistent evidence that volunteering and informal support giving are related to positive outcomes. Preliminary evidence suggests volunteering is related to fewer negative outcomes, but this relation has not been demonstrated in well-designed intervention studies. Informal support giving does not have a clear relation with fewer negative outcomes. Thus, support giving interventions may be effective in improving positive aspects of mental health in older adults. However, it is not clear whether volunteering or informal support giving can be used to decrease negative mental health outcomes. Recommendations for future research include clarifying the definition of support giving, expanding the number of well-designed intervention studies, identifying potential modifiers like social roles, controlling for confounding variables like disability, and using samples that are more diverse. Providing support is a unique and understudied aspect of social interactions that has potential to improve older adult well-being.

### THE RELATIONSHIP BETWEEN SOCIAL NETWORK TYPE AND NEGATIVE SOCIAL INTERACTION

I. Nam, *School of Social Work, Univeristy of Pittsburgh, Pittsburgh, Pennsylvania*

Despite an increase in research focused on the effects of negative social interaction on emotional health, little is known about the determinants of negative social interaction. Social network has been considered as a buffering factor as well as a stressor. This study examined the effect of social network type on negative social interaction. Data were from the Resources of Enhanced Alzheimer's Caregiver Health project. Participants (N = 793) were asked three questions relating to their social network with relatives and two questions relating to their social network with friends. Participants were also asked three questions concerning negative social interaction with others. A structural equation path model was used to examine the relationship among social network type and negative social interaction. There were good model fits to the observed data (CFI = .94; SRMR = .04; RMSEA = .07). Positive and negative predictions of negative interaction by social network were found to be significant. While a person with bigger social network with relatives is more likely to have negative social interactions, a person with bigger social network with friends is less likely to have negative social interaction. These results revealed that social network played an important and complex role in predicting negative social interaction of dementia caregivers. In addition, the results demonstrated the different effect according the type of social network in explaining the negative social interaction of caregivers of a demented family member. The results added information to our understanding of the structure of social networks.

### CONTINUITY AND CHANGE IN POSITIVE AND NEGATIVE SOCIAL EXCHANGES ACROSS ADULTHOOD

H. Ahn, *SOCIAL WORK, UNIVERSITY OF WISCONSIN MADISON, Madison, Wisconsin*

Research demonstrated substantial changes in social relations over time across adulthood. Socioemotional selectivity theory (Carstensen, 1992) suggests that an individual's pursuit of a social goal that varies as a function of age leads to different patterns of social relations across adulthood. There still remain many ambiguities, however, about the longitudinal patterns of change in social relations. Do positive and negative aspects of social relations (i.e., positive and negative exchanges) show similar patterns of change over time? Do the longitudinal patterns of change in social relations vary by respondents' gender and age? A series of 3(age groups) by 2(gender) by (time) analyses of variance, with repeated measures on time, were conducted to examine these questions. Data were from the Americans' Changing Lives study, for the subgroup of adults aged 24 to 96 (n=2,867) who participated in wave 1 (1986) and wave 2 interviews (1989). Older adults were found to maintain higher levels of positive exchanges with children and spouses than younger and middle-aged adults. In addition, considerable continuity in positive exchanges with children was found among older men and women. Declines in positive exchanges with spouses were observed across all age and gender groups. As expected, older adults reported least frequent experiences of negative exchanges with others, whereas younger adults revealed most frequent experiences of them. Negative social exchanges with children and friends increased over time among older men but not among other groups. Findings demonstrated substantial variability in longitudinal patterns of change in social exchanges across age and gender groups.

### WHAT'S IN A MEAL? RETIREMENT HOME TABLEMATE SOCIAL INTERACTIONS AND THEIR INFLUENCES

H. Keller, L. Curle, *Family Relations and Applied Nutrition, University of Guelph, Guelph, Ontario, Canada*

Social interaction is thought to be important for food intake and may improve consumption by older adults living in facilities. This study describes the social interaction that occurs among tablemates at mealtime in retirement homes, as well as those things that influence resident-to-resident interaction. Fourteen lunch time periods in a medium –sized retirement home (n~100) were the basis for qualitative participant observation. Two or three researchers collected data in each period, with each observing two tables, resulting in 63 individual table observations. The type, extent, and influences on social interactions among tablemates were recorded in detailed field notes. Qualitative thematic analysis, using a constant comparison procedure, was used to summarize and make sense of the data. A variety of social interactions occurred among tablemates including: making conversation, providing assistance, sharing, humouring, non-verbal expressions, appreciation and affection, and rebuffing, ignoring or excluding. Interactions were influenced by apparent tablemate roles (e.g. spectator), resident characteristics (e.g. language, health), staff, and the environment. Social interactions or lack thereof are believed to support or hinder the mealtime environment and thus food intake. Describing the types of interaction and monitoring what influences them is a first step towards promoting positive social engagement and improved food intake among tablemates.

## SESSION 1040 (SYMPOSIUM)

### THE INVOLVEMENT OF WOMEN IN THE WIDOWER'S TRANSITION

Chair: *A.J. Moore, Psychology, Ashland University, Ashland, Ohio*
Co-Chair: *D. Stratton, Psychology, Ashland University, Ashland, Ohio*
Discussant: *L.K. Soulsby, University of Liverpool, Liverpool, United Kingdom*

Widowhood is generally thought to be the province of older women, but many men also face the loss of spouse. Stereotypes of men feeling lost without a woman's care of domestic duties and of men needing a woman's companionship dominate the view of older widowers' needs. Men have a larger pool of available potential mates because of women's greater longevity and the social acceptability of older widowed men marrying younger women. Current research finds that widowed men interact frequently with women and get a variety of needs met in those interactions. This symposium highlights the ways that men interact with women, their motivations for doing so, and the presentation of their masculine selves in such interactions. Complex patterns emerge from the qualitative data collected in three separate studies of older widowed men in the United States, Canada, and the United Kingdom. Moore and Stratton explore numerous ways in which men interact with a "current woman" in their lives for tasks that are instrumental, emotional, or a combination. They consider whether men are protecting their masculinity or broadening it as they relate to the "current woman." Bennett's sample of men valued companionship but not remarriage. They expressed ambivalence about a new relationship, fearing the restrictions of a new marriage and still idealizing their deceased wives. Van den Hoonaard finds widowed men seriously considering new intimate relationships—even with some ambivalence—and doing so with definite beliefs about innate differences based on gender. Soulsby acts as discussant.

### FINDING THE NEW "NORMAL": A WIDOWED MAN AND THE "CURRENT WOMAN"

A.J. Moore, D. Stratton, *Psychology, Ashland University, Ashland, Ohio*

Older men experience loss in reciprocal roles when their wives die. A study of 70 older widowed men reveals a variety of ways in which men adjust to that loss. In almost every case, a "current woman" was involved in helping the man in some "womanly" way, from giving advice to being a good listener to becoming his new partner. Activities involved in a "current woman" relationship are identified as instrumental, emotional, or a combination. Seeking instrumental help can have emotional motivation; also, motives for contact can change. Two interactional patterns with instrumental components emerge. In the first, the "current woman" does tasks commonly seen as feminine, allowing the man to avoid those tasks. In the second, the man appears to seek to broaden his own skills so that he can do something his wife had done. These two patterns may represent different ways of considering one's masculinity.

### YOU HAVE TO HAVE SOMEONE: WIDOWERS TALK ABOUT THEIR EXPERIENCES WITH WOMEN

D.K. van den Hoonaard, *Gerontology, St. Thmas University, Fredericton, New Brunswick, Canada*

One of the most ubiquitous stereotypes regarding widowers is captured in the phrase that upon becoming widowed, "women grieve and men replace." This paper looks at how older widowers talked about their relationships with women as participants in an in-depth interview study of twenty-six widowers in Atlantic Canada and Florida who were between 56 and 91 years of age. The researcher analyzed the interviews using discourse analysis with a symbolic-interactionist perspective. The subject of entering into a relationship with and/or marrying a new woman was a top-of-mind issue for these widowers. Their attitudes about repartnering were diverse, often ambivalent, and reflected beliefs about innate differences based on gender. This paper concludes with the suggestion that masculinity has a noticeable effect on the men's interpretation and relating of their relationships with women. Presentation measurable objective: Participants will be able to give two examples of how widowed men's sense of their masculinity as verbalized in their views on repartnering.

### "YOU'RE NOT GETTING MARRIED FOR THE MOON AND THE STARS": OLDER UK WIDOWERS'S AMBIVALENCE TOWARDS NEW RELATIONSHIPS

K.M. Bennett, *Psychology, University of Liverpool, Liverpool, United Kingdom*

Data suggests that older widowers are more likely to remarry than older widowed women. However, relatively little is known about the attitudes of older widowers to new intimate relationships and remarriage. In this study of 60 widowers, more than half discussed their attitudes to, and experiences of, these relationships. However, none of the widowers had remarried and those who described themselves as repartnered were in LAT relationships. The primary reason that men gave for wanting, or participating in, new relationships, was companionship. Relatively few men discussed the desire for sex or the need for domestic comforts. One striking feature was the ambivalence men expressed towards these relationships. Men often made reference to their deceased wife as an ideal. They were also wary of the restrictions that married life might place on them. Thus, the decisions about making new intimate relationships is not as straightforward as might have been thought.

## SESSION 1045 (SYMPOSIUM)

### TIPS FOR SUCCESSFUL CAREERS IN CLINICAL GEROPSYCHOLOGY: RESEARCH, PRACTICE, AND PUBLIC POLICY

Chair: *J.M. Dzierzewski, Clinical & Health Psychology, University of Florida, Gainesville, Florida*
Co-Chair: *S.M. Foster, Univerity of Colorado at Colorado Springs, Colorado Springs, Colorado*
Discussant: *B.G. Knight, University of Southern California, Los Angeles, California*

Clinical geropsychology is an emerging sub-specialty of clinical psychology. The foci of clinical geropsychology includes investigating age-related psychological function, providing clinical care to older adult patients, and advocating for public policy changes that support the mental health of older adults. This symposium will educate emerging students in geropsychology and junior-level geropsychologist about how to best prepare for successful careers in the field. Leaders in the areas of (1) research, (2) practice, and (3) public policy will explore emerging trends and ways to maximize potential within each of these prospective career trajectories. This symposium is geared toward aspiring geropsychologists with questions about possible career tracks within geropsychology. National leaders in geropsychological research, practice, and public policy will provide sage advice garnered through personal experience. Students and junior-level geropsychologists will not only be presented with information regarding careers options, but will also be exposed to "helpful tips" for success in each of the above-mentioned career tracks. Whether students are at the beginning or nearing the end of their graduate experience, they will gain valuable insight and specific tips for negotiating the transition from student to professional geropsychologist. A nationally recognized discussant will then highlight overarching themes between the various careers paths described. Lastly, opportunity will be provided for questions and interaction with symposium participants.

### A SUCCESSFUL RESEARCH CAREER IN CLINICAL GEROPSYCHOLOGY: BARRIERS AND OPPORTUNITIES

S. Meeks, *Dept. of Psychological & Brain Sciences, University of Louisville, Louisville, Kentucky*

The growing field of clinical geropsychology is in desperate need of academic researchers who will expand our scientific base and improve training for the next generation. Barriers to development of new geropsychology researchers include the availability of excellent clinical positions in the VA system, and lack of awareness of, or interest in, clinical geropsychology among other academic researchers, despite relatively strong postdoctoral training and federal funding opportunities. This talk will address promising areas of research, preparation for academic positions, and survival skills for transition from postdoc to faculty positions.

### "POINTS TO CONSIDER IN PLANNING FOR A SUCCESSFUL CAREER PROVIDING PSYCHOLOGICAL CARE TO OLDER ADULTS"

D. Lane, *1. VA Puget Sound Healthcare System, Geriatrics and Extended Care Service, Tacoma, Washington, 2. Univ of Washington School of Medicine, Dept of Psychiatry, Seattle, Washington*

The increasing size of the older adult segment in our population brings new challenges and opportunities for healthcare providers, including psychologists. In the domain of clinical practice, there is a clear need for more geropsychologists (psychologists who specialize in geriatric mental health care). Furthermore, there is an even greater need for general psychologists who are prepared to incorporate working with older adults into their overall practice. As a practicing geropsychologist, the presenter has first-hand knowledge (gained through both didactic coursework and professional experiences) of providing clinical care to older patients. In this talk the presenter will discuss the characteristics that best enable a psychologist to work clinically with older adults, and will share insights gained through years of working with this population. The goal of this talk is to encourage students considering geropsychological practice through providing a balanced and realistic view of what may be expected in practicing as a clinical geropsychologist.

### ADVOCATING FOR PUBLIC POLICIES TO SECURE FUTURE SUCCESSFUL CAREERS IN GEROPSYCHOLOGY

M.P. Norris, *Independent Practice, College Station, Texas*

Whether early career geropsychologists will focus their careers in research or clinical practice, it is imperative that they learn how to advocate for their profession and the recipients of geropsychology services. This presentation will cover: (1) the reasons we need to focus on public policy, (2) fundamentals about the structure and policies of Medicare and Medicaid, (3) recent examples of successes and failures in advocating for public policies that improve geriatric mental health care, and (4) actions that all geropsychologists should take to improve older adults' access to mental health services.

## SESSION 1050 (SYMPOSIUM)

### TRANSITIONS ACROSS THE LIFESPAN AMONG A GROWING RACIAL AND ETHNICALLY DIVERSE POPULATION: ADDRESSING THE HEALTH, SOCIAL, PSYCHOLOGICAL NEEDS, AND POLICY IMPLICATIONS OF AN AGING SOCIETY

Chair: *T. Baker, University of South Florida, Tampa, Florida*

There is a renewed commitment to addressing the health, social and psychological well-being of racial and ethnic elderly minority populations. This is a critical undertaking considering that many minority adults are disproportionately diagnosed with more severe and debilitating physical and psychological illnesses, experience a greater impact on social well-being and financial burdens cross the lifespan, and experience more transitions across the lifespan than majority populations. These processes and transitions of adult development are complex, multifaceted and interrelated. The Task Force on Minority Issues in Gerontology will present a symposium focusing on social, financial, and psychological transitions that impact our growing racial and ethnically diverse aging society. It will highlight on levels of analysis and issues on how various factors are predicated by the relationship and impact on adult development and aging, with policy implications. Presenters will offer a level of expertise on the issues surrounding transitions among various racial and ethnic populations throughout the United States. Dr. David Chiriboga will discuss theoretical models and stages of transitions, while addressing immigration and acculturation experiences among racially diverse groups. Dr. Angelica Herrera will offer information on long-term care needs and policy implications for elderly Mexican-Americans. Dr. Mindi Spencer will provide an overview of health-related quality of life and caregiving and social needs among elderly American Indians. Finally, Ms. Sontra Carmouche will discuss the challenges facing social and psychological transitions, post hurricane Katrina, experienced by local elderly minority communities in New Orleans.

### TRANSITIONS ACROSS TIME AND SPACE

D.A. Chiriboga, Y. Jang, *Aging and Mental Health Disparities, University of South Florida, Tampa, Florida*

The concept of transitions originated in the early 1900s, with studies of how agrarian societies handled comprehensive role and status changes associated with such normative and public circumstances as reaching adulthood, marriage, and death. The three stages in the classic transitions model include (1) letting go, (2) learning what how to behave in the new set of roles, and (3) re-entering society. More recently the concept has been applied to unexpected as well as expected changes in more developed societies such as the United States. This presentation begins with a consideration of theoretical models of transitions, and then presents findings from three studies of transitions. The first is a life span study of marital separation that included non-Hispanic Whites, Blacks, Hispanics, and Asians. The second and third consider the immigration experiences of Mexican American and Korean elders, from the perspective of acculturation as a marker of the transitional experience.

### MEXICAN AMERICAN FAMILIES' LONG-TERM CARE PREFERENCES: POLICY IMPLICATIONS OF COMPETING CULTURAL TRADITIONS, NEED, AND STRUCTURAL BARRIERS

A.P. Herrera[1], J.L. Angel[2], *1. Geriatric Psychiatry, UCSD, La Jolla, California, 2. University of Texas at Austin, Austin, Texas*

For Mexican-American families, taking care of frail and disabled relatives at home has been a time-honored cultural tradition. Reliance on family caregivers for long-term care, however, is being challenged by increasing rates of disability, changing family dynamics, diminishing resources, and geographic mobility. The national trend toward cost-saving home and community based services (HCBS) offer promising alternatives. We draw on epidemiologic and qualitative data to inform an overarching framework of Mexican Americans' use of and preferences for a range of institutional long-term care and HCBS (e.g. hospice, ADHCs). Our findings indicate that long-term care use is driven by caregivers' complex negotiation between cultural norms (e.g., familism, gender roles), caregiver burden, accessibility of linguistically and culturally congruent services, family support, and elders' eligibility for public sources of long-term care funding, such as Medicaid. Additional model testing is critically needed to ensure accurate projections of long-term care needs and costs in this community.

### THE CHALLENGES FACING THE ELDERLY DISPLACED AFTER HURRICANE KATRINA AND ISSUES ASSOCIATED WITH REBUILDING

T. Baker[2], S.M. Carmouche[1], *1. New Orleans Council on Aging, New Orleans, Louisiana, 2. University of South Florida, Tampa, Florida*

The elderly in New Orleans enjoyed an array of social, recreational, and nutritional services provided by the New Orleans Council on Aging (NOCOA) /Orleans Area Agency on Aging to remain independent. Outreach efforts to locate seniors, who were displaced after Hurricane Katrina made landfall on August 29, 2005, in the neighboring communities included working with shelters that were operated by community organizations, churches, the American Red Cross and the Federal Emergency Management Agency. When NOCOA returned to New Orleans in January 2006, it begin to re-build programs that were previously offered while creating new services to deal with some of the challenges facing seniors who had returned to the sparsely populated neighborhoods with limited resources. While it has been over four years since the storm, challenges facing the elderly and the agency are still constant.

### HEALTH-RELATED QUALITY OF LIFE AMONG AMERICAN INDIANS ACROSS DIFFERENT CAREGIVING TYPES: LESSONS FROM THE EARTH STUDY

S. Spencer[1], R. Goins[2], L.C. McGuire[3], J.A. Henderson[4], J. Goldberg[5], *1. Health Promotion, Education, and Behavior, University of South Carolina, Columbia, South Carolina, 2. West Virginia University, Morgantown, West Virginia, 3. Centers for Disease Control and Prevention, Atlanta, Georgia, 4. Black Hills Center for American Indian Health, Rapid City, South Dakota, 5. University of Washington and Seattle Department of Veterans Affairs, Seattle, Washington*

Data from the Education and Research Towards Health (EARTH) study were used to examine health-related quality of life (HRQoL) as measured by the SF-12 among a large sample of American Indian caregivers and noncaregivers to investigate variations in mental and physical HRQoL based on care recipient characteristics. We classified participants as noncaregivers (n = 3610); routine caregivers, who provide personal care to an adult (n = 467); or specialized caregivers, who provide personal care to an adult with mental or physical difficulties (n = 286). Results indicated that noncaregivers reported significantly better mental health than either routine or specialized caregivers ($p < 0.01$), while specialized caregivers had the worst physical health ($p < .01$). These results suggested that mental health might be compromised by providing care to an adult, regardless of care recipient need. However, specialized caregivers are at greatest risk for the deleterious physical effects associated with caregiving.

## SESSION 1055 (PAPER)

## WELL-BEING OF OLDER IMMIGRANTS

### MENTAL HEALTH AND CULTURAL IDENTITY AMONG OLDER NEW AMERICANS: A CROSS-SECTIONAL STUDY OF BOSNIAN REFUGEES IN ST. LOUIS

H. Matsuo[1], A. Karamehic-Muratovic[2], L. Willoughby[1], W. Cheah[3], *1. Saint Louis University, St. Louis, Missouri, 2. Missouri Institute of Mental Health, St. Louis, Missouri, 3. Southern Illinois University at Edwardsville, Edwardsville, Illinois*

Previous studies with refugees and immigrants suggest that poorer mental health is associated with lower levels of ethnic identity and higher levels of acculturative stress. Few studies have, however, examined these relationships among older refugees. The goal of this study was to examine the relationship between psychological distress and indicators of cultural identity among older adults within the St. Louis Bosnian refugee community, as well as to compare this relationship with the same one for a younger cohort of adults. Secondary analyses were performed on a sample of Bosnian refugees in St. Louis who responded to a mail-in and in person mental health and substance abuse assessment. The sample included individuals who have resided in the U.S. for at least 5 years, arrived in the U.S. at age 45 or older, and completed cultural identity indicator questions. Compared with younger adults (age 50-59 years, n=43), the older adults (age 60 and above, n=22) had higher levels of depression, paranoia, and somatic symptoms (all M-W-U $Ps<.05$). Correlation analyses revealed that while stronger ethnic identity was associated with lower levels of depression and anxiety symptoms among young adults, this relationship was not observed with older adults. Instead, identity with U.S. values among older adults was positively correlated with symptoms of depression and anxiety. Future research should highlight the importance of ethnic identity and integration when considering the mental health of older refugees.

### VULNERABILITY OF LATINO AND ASIAN IMMIGRANT ELDERS WITH LIMITED ENGLISH PROFICIENCY: RESULTS FROM THE CALIFORNIA HEALTH INTERVIEW SURVEY

C.B. Worley[1,2], G. Kim[1,2], R.S. Allen[1,2], L.D. Vinson[1,2], M.R. Crowther[1], P. Parmelee[1,2], *1. Department of Psychology, University of Alabama, Tuscaloosa, Alabama, 2. Center for Mental Health and Aging, Tuscaloosa, Alabama*

Language barriers pose problems in health care for foreign-born individuals in the United States. The purpose of this study was to explore linguistic disparities in health status and health service use among Latino and Asian immigrant older adults. Drawn from the California Health Interview Survey (CHIS), Latino and Asian immigrant adults aged 60 or older (n = 1,745) were included in the present analysis. Background characteristics, health status, and health service use and barriers to service use were compared across three language groups in Latinos and Asians. These three groups included 1) older adults who have limited English proficiency (LEP), 2) older adults who are proficient in English but also speak another language at home (EP), and 3) older adults who speak English only. Results showed that Latino and Asian elders with LEP tended to have poorer self-rated health and higher psychological distress compared with EP and English only groups. Latino and Asian elders with LEP were less likely than EP and English only groups to use health services. Barriers to service use (e.g., difficulty understanding written information at doctor's office) were evident among Latino and Asian LEP elders. Findings from these results suggest that Latino and Asian elders with LEP are at high risk for poor physical and mental health outcomes and inadequate health care. Health care systems must be poised to address language needs of older immigrant adults in order to reduce linguistic disparities, improve access to care, and ultimately improve health status for these vulnerable populations.

### EXPLORING THE LOCAL, NATIONAL AND TRANSNATIONAL SOCIAL NETWORKS OF OLDER PEOPLE FROM BANGLADESHI AND PAKISTANI COMMUNITIES LIVING IN THE UK

C. Victor[1], W. Martin[1], M. Zubair[2], *1. Brunel University, Uxbridge, United Kingdom, 2. University of Reading, Reading, United Kingdom*

Introduction: Within the next 20 years the proportion of older people living in minority black and ethnic communities within the UK will significantly increase and this rise will be especially notable within Bangladeshi and Pakistani communities. However, we know little about growing older within these transnational communities. In particular, there is limited evidence documenting the family and social networks of these groups and how these relationships are experienced and mediated across both time and space. Methods: In this paper we draw on data from our ESRC New Dynamics of Ageing project: Families and Caring in South Asian Communities to explore our participants' social networks and family relationships using both our 110 semi-structured interviews conducted with a diverse group of Bangladeshi and Pakistani men and women aged 50+ years and the social network 'maps' created by 109 of these participants. Findings and Conclusions: We first examine the range of styles within which participants created their network maps which ranged from 'traditional' networks diagrams to 'lists' of the geographical location of network members. Of the 109 network maps, 42 were drawn as spidergrams/maps and the remaining 67 as lists or other textual forms. We then explore the social networks depicted in these maps and consider the interconnections between the descriptions of participants' social networks and their spatial location provided in the interviews with those derived from the social network maps. This process highlights the complex spatial dimension of family and social relationships which are expressed at local, national and transnational levels.

### PRIMARY CARE AND RECEIPT OF PREVENTIVE SERVICES AMONG OLDER IMMIGRANTS IN CALIFORNIA

A. Chattopadhyay, *University of California at San Francisco, San Francisco, California*

This study examines the effects of race/ethnicity and U.S. nativity on utilization and outcome of primary care services to determine whether immigration status is associated with increased racial/ethnic disparities in primary care. The data come from the 2001 California Health Interview Survey. Access to primary care is measured by presence of a usual source of care; utilization is measured by physician visits in the past year, receipt of flu vaccination and other age appropriate tests. Also examined are rates of hospitalization and emergency department (ED) visits for ambulatory care sensitive conditions (ACS) as a marker for quality of primary care. Hospitalization and ED visits for ACS conditions such as Diabetes and Asthma indicate inadequate primary care. Elderly persons who self report the presence of these conditions constitute the population at risk for this analysis. Bi-variate analysis reveals that immigrants are significantly less likely to have access to a usual source of care and utilize less primary care services, including fewer physician visits. Despite the seeming inadequacy of primary care services, immigrants have lower rates of ACS hospitalization and ED visits. Multivariate logistic regression with race/ethnicity and nativity as predictors of ACS hospitalization/ED visit, adjusting for demographic, socioeconomic status (education, poverty level), insurance status and having a usual source or care also revealed relatively better outcome for the foreign-born population

### DOES AGE MODERATE BARRIERS TO THE PUBLIC INCORPORATION OF LATINO AND ASIAN IMMIGRANTS IN THE UNITED STATES?

Y. Fan, M. Silverstein, *University of Southern California, Los Angeles, California*

Since1965 sources of immigration to the United States have shifted from European points of origin to those in Latin American, Asia, and the Caribbean. However, little is known about the experience of older immigrants from these regions and their successful incorporation and acculturation to U.S. society. This paper examines how a different perception of social fear among older Asian and Latino immigrants is formed by acculturation factors, such as preferred language use, and by demographic factors such as race, national origin and age. Social fear is defined as being socially excluded by being treated dismissively in public life. We use data from the National Latino and Asian American Study conducted from 2001 to 2003, selecting those over 50 years of age (N=1285). We find that aging immigrants' race and language base predict how strongly aging immigrants feel they have been treated without courtesy in daily life. Aging immigrants from Vietnam and Cuba feel they have been treated more courteously than immigrants from Mexico and China. Age and number of years in the U.S. are negatively related to respondents' perception of public hostility. Results suggest that the age moderates the effect of race and poor English language proficiency on the risk of experiencing a hostile public environment. Age may temper race- and language-based barriers to the public incorporation of immigrants through social interaction. Whether this effect is due to greater respect accorded elders or their marginalized (i.e., non-threatening) status is a question discussed in terms of competing explanations.

## SESSION 1060 (SYMPOSIUM)

### BODY COMPOSITION IN OLD AGE: CAUSES AND CONSEQUENCES

Chair: *A. Koster, National Institute on Aging, Bethesda, Maryland*
Co-Chair: *S. Steholm, National Institute for Health and Welfare, Turku, Finland*
Discussant: *S.B. Kritchevsky, Sticht Center on Aging, Wake Forest University School of Medicine, Winston-Salem, North Carolina*

Body composition changes with age with a tendency to gain fat mass and lose muscle mass and strength. These changes in body composition have been linked to increased risk of disability and poor health. This symposium will explore some causes and consequences of an unfavorable body composition in old age. Low muscle strength is a stronger predictor of functional limitations and poor health than low muscle mass. Therefore, it is important to understand what factors are associated with muscle weakness. Stenholm and colleagues evaluate the association between obesity duration and muscle strength in old age in a representative Finish population. Body fat distribution also changes with age with increases in abdominal visceral fat and intramuscular fat and declines in subcutaneous fat. In particular, visceral fat has been strongly associated with metabolic risk while subcutaneous thigh fat has been associated with a more favorable metabolic profile. Kim and colleagues present the combined relations of visceral fat and thigh subcutaneous fat with metabolic syndrome in the AGES-Reykjavik Study. The association between fat distribution and mortality has not been studied extensively and is the focus of the last two presentations. The associations between specific fat depots in the abdomen and thigh with mortality are evaluated by Koster and colleagues in the AGES-Reykjavik Study and by Harris and colleagues in the Health ABC Study. This symposium provides a better understanding in how obesity duration is related muscle weakness in old age and how specific fat depots are related to metabolic syndrome and mortality.

### ASSOCIATION BETWEEN WEIGHT HISTORY AND MUSCLE STRENGTH IN OLDER ADULTS

S. Steholm[1], J. Sallinen[2], A. Koster[3], T. Rantanen[2], P. Sainio[1], M. Heliövaara[1], S. Koskinen[1], *1. Department of Health, Functional Capacity and Welfare, National Institute for Health and Welfare, Turku, Finland, 2. University of Jyväskylä, The Gerontology Research Centre, Jyväskylä, Finland, 3. National Institute on Aging, Laboratory for Epidemiology, Demography and Biometry, Bethesda, Maryland*

This study aims to examine the association between weight history and muscle strength, and whether the association is mediated by inflammation and insulin resistance. Based on a nationally representative sample of the Finnish population of 55 years and older (1138 women and 883 men), body mass and body height, maximal hand grip strength, C-reactive protein (CRP), insulin resistance, were measured. Recalled weight at 20, 30, 40, and 50 years of age were recorded. Earlier onset of obesity was associated with lower hand grip strength ($p < 0.001$) after controlling for age, sex, education, smoking, alcohol use, physical activity, several chronic diseases and current body weight. The associations remained highly significant even after adjusting for current CRP and insulin resistance and these variables had only minor role in explaining the association between weight history and hand grip strength. In conclusion, long-term exposure to obesity is associated with processes leading to declined muscle strength.

### JOINT ASSOCIATION OF VISCERAL AND THIGH SUBCUTANEOUS FAT WITH THE METABOLIC SYNDROME: THE AGES-REYKJAVIK STUDY

L. Kim[1,3], A. Koster[1], G. Eiriksdottir[2], S. Sigurdsson[2], P.H. Chaves[3], L.J. Launer[1], V. Gudnason[2,4], T. Harris[1], *1. National Institute on Aging/ NIH, Bethesda, Maryland, 2. Icelandic Heart Association, Kopavogur, Iceland, 3. Johns Hopkins University, Baltimore, Maryland, 4. University of Iceland, Kopavogur, Iceland*

This study examined the joint association of visceral adipose tissue (VAT) and thigh subcutaneous adipose tissue (ThSAT) with the metabolic syndrome (MetS). We analyzed data from 1169 obese older adults (BMI>30kg/m2) in the AGES-Reykjavik Study. VAT and ThSAT were measured by CT, with high and low levels defined by the highest and lowest tertiles, respectively. Prevalence of MetS in the low VAT/ high ThSAT group was 34% among women and 46% in men, and markedly higher in the high VAT/ low ThSAT group, with 71% of women and 75% of men affected. After adjusting for age and other key factors, the odds of MetS in the high VAT/ low ThSAT group was significantly higher compared to the low VAT/ high ThSAT group (women: OR=5.14, 95%CI 2.76-9.59; and men: OR=3.88, 95%CI1.48-10.16). In the obese, a regional fat distribution of higher VAT and lower ThSAT is associated with increased metabolic risk.

### FAT DISTRIBUTION AND MORTALITY: THE AGES-REYKJAVIK STUDY

A. Koster[1], L.J. Kim[1], G. Eiriksdottir[2], V. Gudnason[2], T. Aspelund[2], L.J. Launer[1], T. Harris[1], *1. National Institute on Aging, Bethesda, Maryland, 2. The Icelandic Heart Association, Reykjavik, Iceland*

This study examined associations between fat distribution and all-cause mortality. Data were from 2207 men and 2940 women, aged 66-96 years in AGES-Reykjavik Study. Abdominal visceral fat (VAT) and subcutaneous fat (SAT), and thigh intermuscular fat (ThIMF) and subcutaneous fat (ThSAT) were measured by CT. Over on average 4.8 years of follow-up, 401 men and 335 women died. In men, every standard deviation (SD) increase in ThIMF was related to a significantly greater mortality risk (HR:1.18, 95%CI:1.05-1.31) after adjustment for age, education, smoking status, height, and BMI. The abdominal fat depots were not associated with mortality risk in men. In women, a 41% increased mortality risk was found per SD increase in VAT (HR:1.41, 95%CI:1.21-1.63) while fat depots in the thigh were not associated with mortality. Fat distribution related to mortality differed between men and women in that the significantly predictive depot was ThIMF in men and VAT in women.

### MAKING SENSE OF BODY MASS INDEX AND BODY COMPOSITION RISK IN OLD AGE: THE HEALTH AGING, AND BODY COMPOSITION STUDY

T.B. Harris[1], A.B. Newman[2], B. Goodpaster[2], S.B. Kritchevsky[3], S. Satterfield[4], S.R. Cummings[5], M. Visser[6], *1. Laboratory of Epidemiology, Demography, and Biometry, IRP, NIA, Bethesda, Maryland, 2. University of Pittsburgh, Pittsburgh, Pennsylvania, 3. Wake Forest University, Winston-Salem, North Carolina, 4. U of Tennessee-Memphis, Memphis, Tennessee, 5. San Francisco Pacific Medical Center, San Francisco, California, 6. Vjre University, Amsterdam, Netherlands*

The relationship of body mass index (BMI) to mortality in old age is controversial. Associations show greater, no, or inverse risk for heavier versus thinner persons. We used data on BMI and body composition (fat percent (F%), leg lean (LL) mass from dual x-ray absorptiometry; visceral fat (VF), thigh muscle mass (TM), thigh muscle infiltrating fat (TMI), thigh muscle density (TMD), and thigh subcutaneous fat (TS). BMI was inversely related to mortality in men; there was no risk in women. BMI risk became positive when adjusted for TM, but TM was no longer significant when adjusted for strength. VF was associated with death, but health conditions and cigarette smoking attenuated these risks, especially in men. BMI in old age is a surrogate for factors that are more proximate causes of mortality. As a result, with age, it is increasingly complex to understand risk of mortality related to simple body weight.

## SESSION 1065 (PAPER)

## EPIDEMIOLOGY OF FUNCTIONAL STATUS

### USING LINKED MEDICARE CURRENT BENEFICIARY SURVEY (MCBS) AND MEDICARE CLAIMS HISTORY DATA FOR RETROSPECTIVE ACTIVE COHORT STUDIES OF CHRONIC CONDITIONS AND FUNCTIONAL DIFFICULTIES

M. Loeb, Y. Gorina, N. Elgaddal, M. Eberhardt, *National Center for Health Statistics, Hyattsville, Maryland*

The number of older persons living with chronic conditions, such as diabetes, heart disease, and dementia has increased significantly. About 83 % of Medicare beneficiaries have at least one chronic condition. Since 1991, The Center for Medicare and Medicaid Services (CMS) has conducted the MCBS (an active cohort survey), and collects Medicare claims data available at the time of the survey. The recent development of the Chronic Condition Warehouse (CCW) and linkage to Medicare claims submitted prior to and after the survey for more than 92,000 MCBS participants allowed us to build an analytic database and compare changes in functional difficulties among persons with and without specific chronic conditions. Diabetes was selected as pilot condition because, if improperly managed, it may lead to debilitating complications and hasten the loss of functional activities. We used data collected by CMS from 1991 to 2006. Preliminary findings indicate that about 27% of cohort participants aged 65 and over either self-reported diabetes during their MCBS interviews or had Medicare claims data indicating diabetes based on the current CCW algorithm. About 55% of non-diabetic cohort members had severe functional difficulties versus 75% of diabetic cohort members. The difference in the percent with severe complex activities limitations is about 10% (25% vs. 35% for non-diabetic versus diabetic cohort members respectively). The steps involved in building the database and defining functional and diabetic status will be described. The limitations and benefits of using linked data from the interviews with available claims records will also be discussed.

### OVERT AND COVERT BRAIN IMAGING CHARACTERISTICS OF ADULTS WHO MAINTAIN COGNITIVE FUNCTION VERY LATE IN LIFE

C. Rosano[1], H. Aizenstein[1], A.J. Fiocco[2], A.B. Newman[1], Y. Du[1], V. Venkatraman[1], T. Harris[3], K. Yaffe[2], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, 2. University of California, San Francisco, San Francisco, California, 3. National Institutes of Health, Bethesda, Maryland*

We previously found that half of community-dwelling older adults age without substantial cognitive decline. We now examine the brain characteristics of adults maintaining cognitive function late in life. Brain magnetic resonance imaging (MRI) with diffusion tensor were obtained in 274 participants of the Health Aging, Body Composition Study (82.9 years, 56% women, 42% blacks) who had received regular cognitive evaluation during 10 years prior to the MRI. Overt and covert MRI abnormalities (atrophy and mean diffusivity) were quantified for regions important for memory (hippocampus, entorhinal cortex, parahippocampus) and executive control function (middle frontal gyrus, anterior cingulate, posterior parietal). Random effects models classified participants as maintainers (Modified Minimental State test change: slope> 0), minor decliners (slope: 0-1 SD below mean) or major decliners (slope< 1SD below mean). Between-groups mean differences in MRI measures (units: standard deviation=SD) and p-values were adjusted for age, intracranial and total brain volume. Over 10 years, 59% maintained cognitive function, 36% showed minor decline, and 5% had major cognitive decline. Maintainers had significantly less atrophy in memory-related regions, as compared to the minor decliners (adjusted mean volume difference [95% CI]: 1.3 SD [0.7, 2.3], p<0.0001) and the major decliners (5.9 SD [2.4, 9.5], p=0.001). Compared to the major decliners, maintainers also had less covert abnormalities within memory- and executive control-related networks (adjusted mean MD difference: 5.3 SD [1.8, 8.7], p=0.003). Associations were independent of race, gender, education, smoking and physical activity. Covert characteristics of memory- and executive control function-related regions seems to protect from faster cognitive decline.

### CHRONIC MUSCULOSKELETAL PAIN CONTRIBUTES TO ONSET OR WORSENING OF DISABILITY IN AN OLDER POPULATION

S.G. Leveille[1,2], D. Kiely[3], R. Jones[3,2], R.H. Shmerling[4,2], J. Guralnik[5], J.F. Bean[6,2], *1. University of Massachusetts Boston, Boston, Massachusetts, 2. Harvard Medical School, Boston, Massachusetts, 3. Hebrew SeniorLife, Boston, Massachusetts, 4. Beth Israel Deaconess Medical Center, Boston, Massachusetts, 5. National Institute on Aging, Bethesda, Maryland, 6. Spaulding Cambridge Outpatient Center, Cambridge, Massachusetts*

Chronic pain is associated with disability but few studies have examined the disabling impact of chronic pain over time in an older population. The MOBILIZE Boston Study, a population-based longitudinal study, enrolled 765 community-living adults aged >64y. Participants were assessed at baseline and 18 months, and asked about chronic joint pain locations using a 13-item instrument and pain severity using a subscale of the Brief Pain Inventory (BPI). We used multivariable logistic regression models to determine the relationship between baseline pain and subsequent disability (any difficulty in ADL, IADL and mobility). The onset of new or worsening ADL disability at 18-months was 5.4% of persons reporting no joint pain at baseline, 10.3% of those reporting 1 joint pain site, 16.5% of persons reporting >2 joint pain sites, and 20.2% of those reporting widespread pain at baseline (trend, p-value <0.0001). After multivariable adjustment (sociodemographics, chronic conditions, analgesic and psychoactive medications, physical performance, and baseline disability), for new/worsening ADL disability, the OR for >2 pain sites at baseline was 3.87 (95%CI, 1.81-8.29) and for widespread pain, OR=3.64 (95%CI, 1.49-8.88). Significant associations also were observed for IADL and mobility disability. Baseline pain severity, scored 0-10, showed a linear association with likelihood for new or worsening ADL disability (adjusted OR=1.17 per unit increase, 95% CI, 1.02-1.34). In conclusion, chronic pain location and severity were associated with increased risk for developing new or worsening disability at 18 months. Greater attention to prevention and management of chronic pain may reduce disability in the older population.

### AN ACTIVITY PROFILE OF SENIORS IN CANADA WITH CO-EXISTING VISION AND MOBILITY IMPAIRMENTS

J. Huber[1], J. Miller Polgar[1], B. Chesworth[1], J. Strong[2], J.W. Jutai[3], *1. University of Western Ontario, London, Ontario, Canada, 2. University of Waterloo, Waterloo, Ontario, Canada, 3. University of Ottawa, Ottawa, Ontario, Canada*

Purpose: To examine the prevalence of Canadians over 65 years of age who report a vision impairment, mobility impairment, and both a vision and mobility impairment. We describe the subsequent impact of co-existing health conditions on self-perceived health and restrictions to daily activities in order to better understand the interaction of two health conditions for intervention purposes. Method: Secondary analyses are conducted of the National Population Health Survey (NPHS Cycle 7). Weights are applied to obtain population estimates. Results/Discussion: Self-perceived health in individuals reporting no vision or mobility impairment ("Excellent" confident interval (CI) = 0.943 to 0.944) compared to those reporting both a vision and mobility impairment ("Excellent" CI = 0 to 0) indicates an overall decrease in self-perceived health among individuals living with co-existing vision and mobility impairments. There is a higher reliance on assistance from others in activities of daily when living with co-existing vision and mobility impairments. For example, the mean number of activities requiring help from another person as reported from individuals who have no vision and mobility impairment (Meal prep, mean = 0.039) is decreased compared to individuals with both health conditions (Meal prep, mean = 0.484). Conclusion: From analysis of the NPHS survey, we understand that intervention methods must jointly target vision and mobility impairments since the combined interaction of vision and mobility impairment increases the perception of poorer health and reliance on assistance for activities of daily living compared to individuals reporting one or neither health condition.

## SESSION 1070 (PAPER)

## GETTING AROUND WITH DEMENTIA: INTERVENTIONS TO WATCH

### EFFECTIVENESS OF AN INSTITUTION-BASED GROUP WALKING PROGRAM FOR WANDERERS: A PILOT STUDY

J. Song, J. Park, *College of Nursing, Korea University, Seoul, Republic of Korea*

As one of the non-pharmacological interventions to reduce wandering, walking/exercise group has been suggested to be acceptable and helpful. However, it is mostly based on carers' perception rather than empirical evidence. The purpose of this study was to develop an Institution-based Group Walking Program (IGWP) and examine its effects on behaviors, sleeping, mood, and affect of persons with dementia (PWDs) who wander. The study design was a single case experimental design (n=10) with ABAB type (i.e., baseline-intervention-baseline-intervention). Participants (mean MMSE=11.11; mean age=81; 90% female) were encouraged to walk in a group every evening after meal for 30 minutes from Monday to Friday. The route for walking consisted of slopes and hallways in the facility, and front and back yards outside the facility. Data was collected for four weeks: everyday for affect and sleeping; every week for behaviors (i.e., wandering, agitation, neuropsychiatric symptoms) and mood (i.e., depression). Using repeated ANOVA, within subject effects and within subject contrasts were evaluated. Effect of the IGWP was found on participants' depression (F=5.26, p=.005), neuropsychiatric symptoms (F=5.87, p=.016), total sleeping hours (F=3.99, p=.018), sleeping efficiency (F=3.99, p=.018), frequency of wake-ups (F=5.05, p=.007), and affect (F=12.73, p=.001). Results of this study imply that regular walking program may be beneficial for improving night time behaviors of wanderers rather than decreasing their wandering during the day. Randomized controlled studies and longitudinal studies are necessary to confirm the findings obtained from this study.

### BECOMING LOST IN THE COMMUNITY WHILE DRIVING: ANALYSIS OF THE USE OF THE SILVER ALERT PROGRAM

M. Rowe[1,2], K. Rispaud[3], E. Sheehan[3], *1. Veterans Administration, Tampa, Florida, 2. U. of Florida, Gainesville, Florida, 3. Lantana Police Department, Lantana, Florida*

One event that occurs across all ages of persons with dementia (PWD) is the phenomenon of becoming lost in the community. Commonly called 'wandering', for community-dwelling PWD it rarely is associated with wandering behavior. The purpose of this paper is to describe the phenomenon of becoming lost while driving using data from the Florida Silver Alert program. In the first 8 months of the program, 81 alerts were issued or approximately 2 alerts per week. Most alerts were issued for male drivers (73%) who left in their own car from their home. Males lived predominantly with their spouse (93%), but females who became lost while driving were either living alone (50%), or with adult children or spouse (25% each). Ages ranged from 63 to 92 (mean=78.27) with no significant age difference by gender. Two-thirds became lost when they were driving on a planned, normal outing followed by leaving when the caregiver was sleeping (19%). All but 4 individuals were found alive, most often were at least one county away with 7 in a different state. Dangerous situations encountered included: driving the wrong way on highway, motor vehicle crash, found in woods, lying in interstate median, and stopped on train tracks. One individual drowned after driving into a canal, and another died of exposure after driving into remote woods. Two committed suicide. These data highlight the fact that this phenomenon is not wandering and the dangers of not restricting driving after dementia is diagnosed, particularly of males living with their spouse.

### A RANDOMIZED CLINICAL TRIAL OF THEORY-BASED ACTIVITIES FOR BEHAVIORAL SYMPTOMS OF DEMENTIA

A.M. Kolanowski[1], M. Litaker[2], L. Buettner[3], J. Moeller[1], *1. Penn State University, University Park, Pennsylvania, 2. University of Alabama, Birmingham, Alabama, 3. University of North Carolina, Greensboro, New York*

Objective: To test the efficacy of activities derived from the Need-driven Dementia-compromised Behavior model for responding to behavioral symptoms of dementia in nursing home residents. Design: Randomized clinical trial, double-blind. Setting: Nine nursing homes. Participants: One hundred and twenty eight cognitively impaired residents were randomly assigned to three weeks of activities tailored to: functional level only (n= 32), style of interest only (n= 33), both functional level and style of interest (n= 31): or active control (n= 32). Intervention: Three weeks of tailored activities were provided twice daily for up to 20 minutes each session. Measurements: Research assistants blinded to group assignment assessed agitation, passivity, engagement, affect, and obtained measures of self-reported mood during baseline, treatment, random times outside of treatment, and one week post-treatment. Results: The tailored to style of interest group demonstrated less passivity (p= .02), greater engagement (time on task (p= .004) and level of participation (p= .000), alertness (p=. 003), and attention (p=. 02) than the other groups. The tailored to both functional level and style of interest group demonstrated greater pleasure than the other groups (p = .035). There were no differences in agitation, anger, anxiety or mood by group. Conclusions: Style of interest is a critical component of activity prescription. Exposure to activities that meet needs expressed by personality style of interest may be sufficient to capture attention and reduce passivity in nursing home residents regardless of their ability to actively participate in activities.

### EFFECTS OF PHYSICAL TRAINING ON MOTOR PERFORMANCE IN PATIENTS WITH DEMENTIA (RCT)

K.A. Hauer[1], M. Schwenk[1], T. Zieschang[1], C. Becker[2], P. Oster[1], *1. Geriatric Research, Bethanien-Hospital at the University of Heidelberg, Heidelberg, Germany, 2. Robert Bosch Hospital, Stuttgart, Germany*

Study aim: The aim of this study was to determine the effects of a standardized physical training on motor performance in patients with diagnostically confirmed mild- to moderate-level dementia (N=122). Methods: Effects of a 3 months progressive strength- and functional training (intervention group IG) were compared to a motor placebo activity (control group CG) with a 3-months follow up in a randomized, controlled trial (RCT). Relative increase (%) of functional performance (5 chair stand; 5CS) and maximal strength (1 Repetition Maximum; 1RM) represented primary study endpoints. Established, validated test for function and strength represented secondary study endpoints. Results: Functional performance (5CS: CG: +4.1±25.8 vs. IG: -26.3±14.9; p>0.001) and maximal strength (1RM CG.-1.1±28.6 vs. IG:+56,6 ±42.2%: p<0.001) increased significantly. All tested strength and functional parameters showed significant, overall improvements during training. Group differences were remained significant (5CS: CG: +12.6±63.2 vs. IG:-18.6±20.8; p=0.008. 1RM:CG:+6.6±33.6 vs. IG:44.0±48.3; p=0.001) during follow-up. Linear Regression analysis identified low baseline motor performance (1 RM: p=0.007; beta:-0.375; 5-Chair rise: p<0.001; beta: 0.635) but not level of cognitive impairment (MMSE; p=n.s.), form of dementia (Alzheimer vs. vascular vs. other: p=n.s.) or performance in specific cognitive sub-domains (trail making test, verbal fluency, early /late recall, discrimination; all tests n.s.) as significant predictors of training gains in the IG. Conclusion: The presented training regimen showed high effectiveness to improve overall motor performance independent of level or form of cognitive impairment in patients with dementia. Patients with lower baseline motor performance profited most and improvements gained during training remained during follow up.

## SESSION 1075 (SYMPOSIUM)

### HARMONIZING COHORT STUDIES TO ADVANCE THE SCIENCE OF AGING: THE CANADIAN LONGITUDINAL STUDY ON AGING

Chair: *S. Kirkland, Community Health and Epidemiology, Dalhousie University, Halifax, Nova Scotia, Canada*

Over the next twenty years, the Canadian Longitudinal Study on Aging (CLSA) will generate a wealth of information from 50,000 men and women that will contribute to the advancement of the science of aging and to policy development. In addition to its significant value as a research study, the CLSA team also envisions that it has a key role to play in harmonizing with other national and international studies to conduct cross national comparisons to answer questions related to the impact of varying social policies such as retirement and savings or to join with many research platforms to increase the sample sizes to elucidate the interplay between genes and environment. Such collaborations will allow us to utilize longitudinal cohort studies and population-based biobanks to their fullest potential, ultimately achieving major scientific gains and innovations that would not otherwise be possible. However, comparative or pooled analyses can only be fully realized through the harmonization and sharing of tools, measures and methods. Priority areas of development in harmonization include accounting for variations in study design, data/sample collection and processing, and ethics and governance considerations. Bringing together international leaders in large scale studies and harmonization, the objectives of this symposium are to: (1) highlight the potential benefits, opportunities, and challenges for cross-national harmonization; (2) define the concepts and scope of prospective and retrospective harmonization; (3) discuss harmonization tools and technologies that may enable harmonization between studies; (4) describe ongoing harmonization efforts between the CLSA and other national and international cohorts.

### ADVANCING THE SCIENCE OF POPULATION HEALTH AND AGING THROUGH INTERDISCIPLINARY RESEARCH

C. Wolfson[1], P.S. Raina[2], S. Kirkland[3], *1. McGill University, Montreal, Quebec, Canada, 2. Clinical Epidemiology, McMaster University, Hamilton, Ontario, Canada, 3. Dalhousie University, Halifax, Nova Scotia, Canada*

Canadians are living longer, and older persons are making up a larger share of the population (14% in 2006, projected to rise to 20 % by 2021). The Canadian Longitudinal Study on Aging (CLSA) is a national longitudinal study of adult development and aging that will recruit 50,000 Canadians aged 45 to 85 years of age and follow them for at least 20 years. All participants will provide a common set of information concerning many aspects of health and aging, and 30,000 will undergo an additional in-depth examination coupled with the donation of biological specimens (blood and urine). The CLSA will become a rich data source for the study of the complex interrelationship among the biological, physical, psychosocial, and societal factors that affect healthy aging.

### DATA SETS ON HEALTH AND RETIREMENT: DATA COLLECTION AND SHARING FOR POLICY DESIGN

J. Lee, *RAND, Santa Monica, California*

A growing number of countries are developing or reforming pension and health policies in preparation for population aging and to enhance welfare of their citizens. The adoption of different policies by different countries has resulted in several natural experiments, offering unusual opportunities to examine the effects of varying policies on health and retirement, individual and family behavior, and ultimate well-being. To realize the research opportunities these natural experiments afford, data collection efforts in these countries must be harmonized to the extent possible. An increasing number of countries have agreed to provide harmonized data, particularly with the Health and Retirement Study in the United States. I will introduce a set of internationally harmonized data sets and discuss opportunities for cross-national studies and implications for policy evaluation and design.

### DATASHAPER: IS THERE A POTENTIAL TO SHARE HARMONIZED HIGH QUALITY DATA BETWEEN LARGE POPULATION-BASED STUDIES ACROSS THE WORLD?

I. Fortier[1,2], D. Doiron[1], F. L'Heurex[1], M. Deschênes[1], P.R. Burton[3], *1. P3G Consortium, Montreal, Quebec, Canada, 2. Université de Montréal, Montréal, Quebec, Canada, 3. University of Leicester, Leicester, United Kingdom*

In order to properly understand the role and interaction of genetic, lifestyle, environmental and social factors in modulating the risk and/or progression of chronic diseases, it is critical to have access to very large number of study participants. Thus, although major technical, ethico-legal and scientific challenges are still to be faced, pooling of information between studies is becoming increasingly important. The DataSHaPER (Data Schema and Harmonization Platform for Epidemiological Research (www.p3gobservatory.org) is developed to provide a flexible, but structured approach to the harmonization and pooling of information between studies. A total of 50 large population-based studies (> 5.5 million participants), a third enrolling only participants older than 40, have been part of an initial DataSHaPER project. The project assessed the potential to harmonize 150 core variables selected by international experts. The ability to recreate the variables and answer to specific scientific questions using the platform will be discussed.

### DATASHIELD: INDIVIDUAL-LEVEL META-ANALYSIS WITHOUT SHARING THE DATA

P.R. Burton[1,4], M. Wolfson[2,4], N. Masca[1], N.A. Sheehan[1], I. Fortier[3,4], *1. Departments of Health Sciences and Genetics, University of Leicester, Leicester, United Kingdom, 2. University of Ottowa, Ottowa, Ontario, Canada, 3. University of Montreal, Montreal, Quebec, Canada, 4. Public Population Project in Genomics (P3G), Montreal, Quebec, Canada*

Contemporary research in biosocial science can demand vast sample sizes. Often, data must be aggregated across several studies or data sources to provide adequate power. When a pooled analysis is required, analytic efficiency and flexibility are typically best served by combining the individual-level data from all sources and analysing them as a single large data set. But valid ethico-legal constraints can prohibit or discourage the sharing of individual-level data, particularly across jurisdictional boundaries. This leads to a fundamental conflict between competing public goods. DataSHIELD (Data Aggregation Through Anonymous Summary-statistics from Harmonized Individual-levEL Databases) provides a simple approach to analysing pooled data that circumvents this conflict. Modern distributed computing is used and advantage taken of the properties of the algorithm that iteratively updates parameter estimates in generalized linear modelling (GLM). The presentation will cover the need for DataSHIELD, its theoretic basis, opportunities and challenges, and how to find out more.

## SESSION 1080 (POSTER)

## HEALTH CARE ISSUES AND INTERVENTIONS

### EFFECTS OF MULTIPLE PHYSICIAN PRESCRIBING PATTERNS ON TOTAL NUMBER OF MEDICATIONS AND BEER'S LIST MEDICATIONS IN ELDERS, BEFORE AND AFTER ENROLLMENT IN A MEDICAID HOME AND COMMUNITY BASED WAIVER PROGRAM

R. Haque[1], C.W. Given[1], M. You[2], *1. Department of Family Medicine, Geriatrics, Michigan State University, East Lansing, Michigan, 2. College of Human Medicine, East Lansing, Michigan*

Elders receive scripts for multiple medications from multiple physicians. The poor elderly may receive new scripts when they enroll in a Medicaid Home and Community Based Waiver program. To determine how waiver enrollment is related to changes in prescription medications, we compared scripts prior to and following enrollment for 13,102 patients enrolled in a waiver program between 2002 and 2007. Comparing scripts written 60 days prior, 60 following enrollment, and medications that are on the Beer's list, which is a guide for medications that place the elderly at greater risk for poor outcomes, we found that: First, in the 90 days prior to enrollment patients received 5.74 (6.19) scripts, and 6.31 (5.98) scripts 90 days after. Beer's medications increased from .60(.94) to .66 (.94). Further increase in Beer's medications is mediated by the total number of medications. Second, patients who retained the same physician prior to and following entry actually had a decrease in medications following enrollment, 5.49 (4.46) compared to 3.98 (.08). Those having physicians prescribing prior and following and new physicians following enrollment had 10.22 (5.40) prior and 8.40 (.06) after enrollment. Those with only new physicians gained over two medications, and the pattern was the same for increase in Beer's list medications. These data clearly indicate that waiver agents who manage the care of persons following entry into the waver program need to evaluate carefully patients and their medications at entry and immediately following to assure each is clinically indicated and possible adverse drug reactions are minimized.

### RURAL/FRONTIER HEALTH PROFESSIONALS: NEEDS AND PREFERENCES FOR TRAINING IN GERIATRICS

C. McKibbin[1,2], D. Welsh[1], D. Fleming[1,2], A. Lavery Benson[1,2], B. Morrow[2], K. Kitchen[1], *1. University of Wyoming, Laramie, Wyoming, 2. Wyoming Geriatric Education Center, Laramie, Wyoming*

There is a dearth of geriatric trained providers in rural/frontier communities. The purpose of this study was to seek input from health professionals practicing in a rural/frontier state on their perceived training needs, interests, as well as preferred content and format for geriatric training. Two-hundred sixty three health professionals, currently practicing in the state of Wyoming, completed the survey. Nursing professionals represented the largest proportion of respondents (n=104, 39.6%). Other professions represented included medicine, social work, dentistry, pharmacy, and physicians. All participants were recruited from existing lists maintained by Wyoming professional licensing boards. Results showed that a majority had no formal training in geriatrics (n=196, 74.5%) and many (i.e., n=73, 27.8%) had not had any geriatric-related continuing education in five or more years. Motivation for training was "high" or "very high" for nearly one-half of respondents (n=130, 49.5%), though the majority do not have opportunities to attend educational offering in geriatrics (n=141, 53.6%). The largest barrier to obtaining geriatric training was proximity to training sites (n=111, 42.2%). Training format preferences included internet or web-based training, professional conferences, and/or self-study written materials. Professionals were most interested in receiving training in adapting treatments to older patients, knowledge of age-related diseases (e.g., dementias), geriatric assessment, medication use and misuse, mental health and depression, and end of life/palliative care. These data can be helpful in preparing curriculum for continuous education programs in geriatrics that meet the needs (e.g., content, delivery type) of health care professionals in Wyoming.

### EARLY EFFECT OF A PREVENTIVE HOME VISIT PROGRAM FOR AMBULATORY FRAIL ELDERS IN JAPAN: A RANDOMIZED CONTROLLED TRIAL

A. Kono[1], Y. Kanaya[1], T. Fujita[1], C. Tsumura[2], T. Kondo[3], K. Kushiyama[4], L. Rubenstein[5], *1. School of Nursing. Osaka City University, Osaka, Japan, 2. School of Nursing & Rehablitation, Konan Women's University, Kobe, Japan, 3. Municipal Community-based Comprehensive Care Center, Izumi Otsu, Japan, 4. Department of Health and Welfare, Misaki Local Goverment Office, Misaki, Japan, 5. Sepulveda VA GRECC, School of Medicine, UCLA, Los Angeles, California*

Programs of preventive home visits for ambulatory frail elders certified as eligible for long-term care services in the Japanese public long-term care insurance system, but who are not yet using these services, are not widely available. The aim of the present analysis from a randomized controlled trial was to identify early effects of a pilot preventive home visitprogram for such elders living in three communities. Eligible and willing subjects (n=323) were randomly assigned to intervention (n=161) or control group (n=162). Community health nurses and care managers provided structured preventive home visits to intervention group subjects every six months over one year. Outcome measures including ADLs, IADLs, depression, and social support were collected via mail questionnaire at baseline and at the 12-month follow-up point. At follow-up, 5.0% of intervention group subjects had died vs 6.8% of control group subjects, and 2.5% of intervention group subjects were in nursing homes vs 1.0% of control group subjects (NS). Two-way ANCOVA adjusting for each baseline score of outcome measures, has shown that scores of depression in the intervention group had improved significantly more than those in the control group (p=0.014). These results suggest that the preventive home visitation in one year might be beneficial in preventing depressive symptoms in the present population. We are continuing the trial for another two years to test longer-term effects.

### MEDICATION-RELATED PROBLEMS EXPERIENCED BY PATIENTS IN A TRANSITIONAL CARE PROGRAM

J.E. Edgell[1], K.A. Cappuzzo[2], B. Hungate[3], P. Slattum[1], *1. Department of Pharmacotherapy and Outcomes Science, Virginia Commonwealth University, Richmond, Virginia, 2. Amgen Scientific Affairs, Providence Forge, Virginia, 3. Virginia Commonwealth University Medical Center, Richmond, Virginia*

Background: Frail older adults with multiple co-morbidities are especially prone to frequent emergency department visits and hospitalizations. Fragmented medical care for the older adult contributes to repeated utilization of resources. Hospital-based transitional care programs are attempting to reduce these avoidable encounters and improve patient outcomes. Two Nurse Practitioners in the transitional care program at Virginia Commonwealth University Medical Center in Richmond, Virginia visit high risk patients in their home post hospital discharge. Primary care medical management is provided, including medication management. Objective: The objective was to characterize patients participating in a transitional care program, focusing on medication-related problems experienced by these patients. Methods: Charts were reviewed for all patients enrolled in the transitional care program in 2005. Demographic information, reason for initial hospital admission, co-morbidities, discharge medications, and issues related to medications were obtained from documentation of the first home visit after discharge. Medication-related problems were classified as nonadherence, underuse, overuse, inappropriate medication, adverse drug event or drug-drug interaction. Results: Forty-one patients (average age 75.5 years; 69% female) participated in the program in 2005. The most prevalent comorbid conditions among participants were hypertension (17%), diabetes (11%) and CHF (11%). Nonadherence was the most commonly reported medication-related problem (40%). Underuse (29%) and overuse (17%) also were common. Many of the problems identified are preventable. Conclusion: Medication-related problems are a common source of complications in transitional care patients. Pharmacists are uniquely trained to evaluate medication regimens, and have the potential to improve outcomes as part of the transitional care team.

### RISK FACTORS ASSOCIATED WITH 30 DAY HOSPITAL READMISSION IN NURSING HOME RESIDENTS

A. Chandra, S.J. Crane, S.S. Cha, P.Y. Takahashi, *Mayo Clinic, Rochester, Minnesota*

Objective: To identify risk factors associated with 30 day hospital readmission in patients dismissed to skilled nursing facilities (SNF). Design: This was a retrospective cohort study. Patient demographic, comorbid and functional status were collected from the electronic medical record. Readmission to the hospital within 30 days was the primary outcome. An initial univariate evaluation determined significant variables for a multivariable model. A Bayesian approach with simulation from 1000 bootstrap samples was performed to confirm risk factors and validate the final model. Setting: Primary and long term care practice of a teaching institution. Participants: Adults over the age of 60 living in Olmsted County being followed by an academic primary care medical practice on January 1, 2005 and were admitted to a SNF between 1/1/ 2005 to 12/31/2006. Results: 2261 patients dismissed to a SNF in the 2 years following 1/1/2005, were included in the cohort. Of these, 347 (15.3%) were readmitted to the hospital within 30 days. Significant predictors of readmission in the final multivariable model included male gender, advanced age, dementia, chronic obstructive pulmonary disease, hypertension, history of falls, dependence in transfers, and previous emergency room visits. Conclusions: Functional status, prior health care utilization in the form of emergency room visits and comorbid health factors were associated with readmission to the hospital within 30 days in patients from SNF. These risk factors identify the highest risk group in this frail population and could potentially suggest a different care model for patients as they transition across care settings.

### VETERANS HEALTH ADMINISTRATION TELEHEALTH INTERVENTIONS FOR AGING VETERANS: A SYSTEMATIC REVIEW

M. Luptak[1,2], B.L. Hicken[2], R. Hill[3,2], N.K. Dailey[2], R. Rupper[2], C. Peterson[2], B. Bair[2], *1. University of Utah College of Social Work, Salt Lake City, Utah, 2. Veterans Rural Health Resource Center - Western Region, VA Office of Rural Health, Salt Lake City, Utah, 3. University of Utah Department of Educational Psychology, Salt Lake City, Utah*

For well over a decade, the Veterans Health Administration (VHA) has been a leader in the development and implementation of innovative healthcare delivery technologies that have benefited the rapidly aging veteran population. The VHA's leadership in advancing these technologies, along with the establishment of the Office of Rural Health in 2006 to address the care needs of rural veterans (3/4ths of whom are 65 years and older), has positioned telehealth at the front line of healthcare delivery tools within the VHA system. This presentation describes the current state of the research on telehealth interventions initiated and completed under the auspices of the VHA as determined by a systematic literature search of published studies from 2000 to 2009 in four databases (PubMed, CINAHL, NLM, and PSYCINFO). Standard systematic review methods were used to identify replicable controlled empirical trials of telehealth delivery interventions with at least one outcome assessment administered at post-test and at a follow-up interval. Nineteen studies met our inclusion criteria. Themes highlighted across these studies—in which the average age of participants was 65—include the employment of telehealth technology in the management of chronic illness conditions, in addressing mental health concerns through in-home monitoring and treatment, and in facilitating interdisciplinary treatment. These studies suggest that telehealth can facilitate collaborative treatment for aging veterans diagnosed with multiple co-morbidities that make access to facility-based care difficult—particularly in rural and remote regions. Challenges in maintaining stand-alone telehealth interventions within the VHA infrastructure will be addressed along with future directions.

### OLDER PERSONS TRANSITIONS IN CARE – THE OPTIC STUDY

G. Cummings[1], C. Reid[2], N. Keating[1], J. Konnert[3], C. Estabrooks[1], P. Norton[4], A.S. Wagg[1], O. Team[1,2,3], *1. University of Alberta, Edmonton, Alberta, Canada, 2. University of British Columbia, Okanagan, Kelowna, British Columbia, Canada, 3. Interior Health, Kelowna, British Columbia, Canada, 4. University of Calgary, Calgary, Alberta, Canada*

Nursing home residents are predominantly over age 80, female and suffering from dementia, with complex needs and high dependency on care providers. Changes in health status triggered by common events such as illness and injury may necessitate transfer to an emergency department (ED). During these transitions, care often is made more difficult by compromised communication among residential and healthcare facilities, families and clinicians. During transitions, residents are vulnerable to experience care that is delayed, fragmented and potentially unsafe. OPTIC is a comprehensive, multidisciplinary program of research on efficacy of nursing home-ED transfers in two Canadian provinces. Its goal is to improve care for frail elderly nursing home residents. Objectives are: to understand multiple perspectives on what constitutes a successful transfer; to determine costs of transfers from system and family/resident perspectives; to develop a practical tool to assess transfer success, in terms of quality of care and avoidable complications; and to analyze the influence of organizational factors in key practice locations (nursing homes, pre-hospital transport services, and emergency departments) on transfer success. Data collection occurs in two waves: Phase 1 semi-structured interviews with residents and family caregivers who have experienced such transitions and focus groups with care providers in the three practice locations; and Phase 2 real-time case tracking of over 400 transitions during a 12 month period. In this poster, we present the OPTIC model of the transition process, and results of Phase 1 interviews and focus groups, highlighting how they inform development of the Phase 2 tracking tool.

### INSTITUTE OF MEDICINE'S (IOM) "RETOOLING FOR AN AGING AMERICA" – NATIONAL INSTITUTES OF HEALTH (NIH)'S INVESTMENT IN DEVELOPING INNOVATIVE MODELS OF CARE (MOCS)

M. Bernard[1], C. Liggins[1], G. Niederehe[2], C. Hafner-Eaton[3], *1. National Institute on Aging, Bethesda, Maryland, 2. National Institute of Mental Health, Bethesda, Maryland, 3. National Institute of Nursing Research, Bethesda, Maryland*

In 2008, the IOM recommended the inclusion of specific innovative features in new MOCs for older adults to improve patient outcomes. These features include interdisciplinary team care (ITC), care management (CM), chronic disease self-management (CDSM), pharmaceutical management (PM), preventive home visits (PHV), proactive rehabilitation (PR), and transitional care (TC). An analysis was conducted of the extent to which NIH from 1999-2008 has provided support for developing new MOCs that included such innovative features, to determine research gaps and identify opportunities for collaboration. NIH-supported internal grant databases were queried using a variety of search terms related to MOCs. Initially, 369 grants were identified, with 98% funded by National Institute on Aging (NIA), National Institute of Mental Health (NIMH), and National Institute of Nursing Research (NINR). Grants were then reviewed by at least two knowledgeable staff, and excluded if they did not develop interventions and include at least one innovative feature. 194 grants developed and tested MOCs with at least one innovative feature - NIA (33%), NIMH (28%), and NINR (39%). The largest investment was in 'CDSM' (39%), 'PR' (36%), and 'CM' (29%). There was considerable investment in 'ITC' (13%) and 'PHV (7%). The lowest investment was in 'PM' (4%) and 'TC' (2%). Analysis of NIH's efforts provides evidence of significant investment in the development of models of care that incorporate IOM-recommended innovative features. However, there are gaps in some areas that provide opportunities for additional research, and the potential for collaboration with other public and private entities.

### DELIRIUM, IMPAIRED COMMUNICATION, AND DISABILITY INCREASE RISK FOR FAILED TRANSITION FROM HOSPITAL

A.A. Borrud, D.E. Holland, *Mayo College of Medicine, Rochester, Minnesota*

Unplanned emergency department (ED) visits and hospital readmissions within 30 days of discharge may reflect poor quality transitions from hospital. Identifying risk factors for return may improve discharge planning. Many high risk conditions have been identified, but few studies evaluated the contribution of functional impairment. This study sought to identify predictors of unplanned 30 day ED visits and readmissions from information available at the bedside. The unit of analysis was discharge from a hospitalist general medical service during 2008. Only patients residing within a 25 mile catchment area were included to more accurately capture readmissions. Following 911 discharges, there were 42 unplanned ED visits and an additional 165 unplanned readmissions within 30 days. Two-thirds of discharges involved patients 65 and older. Odds ratios ($p < .05$) for an association between unplanned return to hospital and the following factors were found through multivariate regression analysis: age (0.99), moderate to severe disability by the Rankin (1.73), delirium by the Confusion Assessment Method (3.74), verbal communication difficulties (2.81), CHF (1.52), diabetes (1.60), metastatic cancer (2.21), and renal (2.06) and severe liver disease (2.55). This study finds delirium, impaired ability to communicate, and disability associated with failed transitions and confirms prior work identifying high risk diagnoses. Coleman's Care Transition Measure gauges the quality of discharges by patients active participation in the discharge process and their understanding of medication and self-care instructions. This work suggests that delirium and difficulty communicating pose unique obstacles to achieving a patient-centered safe transition from hospital.

### DEVELOPMENT AND EVALUATION OF A SELF-MANAGEMENT PROGRAM INTEGRATED WITH EXERCISE CLASSES FOR THE OLDER ADULTS WITH DIABETES IN KOREA

M. Song[1], Y. Park[1], W. Song[2], B. Cho[3], J. Lim[3], S. Kim[1], W. So[2], *1. College of Nursing, Seoul National University, Seoul, Republic of Korea, 2. Dept of physical education, Seoul National University, Seoul, Republic of Korea, 3. College of Medicine, Seoul National University, Seoul, Republic of Korea*

Background: Long-term self-management is imperative to prevent complications and disabilities for people with diabetes. Although regular exercise is an integral part of self-management, poor-exercise practices have been an issue in diabetes care. Objectives: To develop and test a self-management training program which contain diabetes self-management lecture classes and exercise classes for older adults with diabetes. Method: The authors developed a 12-week-long, diabetes self-management program includes biweekly Thera-band exercise classes and weekly lecture classes based on literature review and field experience. Program evaluation methodology was applied for this action study. Steps of the program evaluation process were: 1) need assessment, 2) process analysis, and 3) outcome evaluation. Outcome evaluation was done by comparing the baseline data with the data from the 13th week of Fasting Blood Glucose (FBG), cholesterol, blood pressure (BP), level of diabetes self-care, and qualitative data from the focus group interviews. Data from the 29 participants recruited from a senior center were utilized for final analysis. Results: Outcome analysis by Wilcoxon Signed Rank test showed significant improvement in FBG (p=.021), diabetes self-care (p=.003), and diastolic BP (p=.042), but no difference was seen in the other variables. The participants reported high satisfaction in the qualitative data. The mean attendance rate of the exercise classes and lecture classes were 91.25% (± 8.31) and 83.09 % (± 13.25) respectively. Conclusion: The results of this study showed some promising effects of the program. The long-term effect of the program on exercise maintenance should be evaluated with a larger sample in the future.

### EFFECTS OF A SIMPLIFIED HOSPITAL ELDER LIFE PROGRAM AT A GASTROINTESTINAL SURGICAL UNIT

C. Chen, M. Lin, *National Taiwan University College of Medicine, Taipei, Taiwan*

Studies have revealed that 34-50% of older patients experienced functional decline during hospitalization. The aim of this study was to evaluate the effects of a simplified Hospital Elder Life Program (HELP) implemented at a Gastrointestinal Surgical Unit, on the prevention of functional decline, defined as a decrement in cognitive, nutritional, and activity of daily living (ADL) functions, during hospitalization and 3 months after surgery. A pre- and post controlled clinical trial design was employed to enroll subjects aged 65 years and older who scheduled for an elective gastrointestinal surgery at a 2000-bed medical center in Taipei, Taiwan. Subjects enrolled during 8/07 to 4/08 were served as the controls (n=82) and subjects enrolled since 5/08 to 4/09 served as the experimental group (n=107). For the experimental group, a simplified HELP protocol including early mobilization, cognitive stimulation, and nutritional assistance (oral care/diet education) was implemented by a trained research nurse during hospitalization. Subjects in the control group received usual care. Functional measures were taken at three points: before surgery, at discharge and 3 months after surgery. Analyses were performed to examine the group differences using SPSS. Preliminary results shown that, at discharge, patients at experimental group had significant less body weight loss (2.2 vs. 3.1 kg, p=0.016), less decline in hand grip strength (1.1 vs. 2.6 kg, p=0.016), and better cognitive, nutritional, and ADL status compared to the controls. The findings support effects of this simplified HELP protocol in preventing functional decline for older patients who underwent elective gastrointestinal surgery.

### THE EFFECT OF TAILORED ACTIVITY PACING ON STIFFNESS IN ADULTS WITH KNEE OR HIP OSTEOARTHRITIS

M.E. Braun[1], S.L. Murphy[2], *1. Psychology, University of Notre Dame, South Bend, Indiana, 2. University of Michigan, Ann Arbor, Michigan*

Osteoarthritis (OA) is a leading cause of disability in older adults. Whereas many rehabilitation interventions for OA are designed to reduce joint pain to increase day-to-day functioning, less is known about the impact of interventions on other symptoms, such as OA fatigue and stiffness. In a recent pilot study, we found that instruction in activity pacing (i.e., balancing activity with rest) that was individually tailored based on how symptoms related to physical activity was effective at reducing fatigue compared to a general approach. The purpose of this analysis was to examine if tailored activity pacing also had an effect on OA joint stiffness. Thirty-two adults with symptomatic knee or hip OA (M=61.9, SD=7.9 years) were randomly stratified by age and gender into the tailored or general activity pacing intervention. All participants met individually with an occupational therapist for two weekly sessions and participated in performance testing and home monitoring of symptoms and physical activity. Stiffness was measured using the Western Ontario MacMaster (WOMAC) stiffness scale, which was completed at pretest, posttest and 10 weeks follow-up. Results indicated that participants in the tailored group reported less stiffness (M=2.73) at 10 week follow-up than those in the general group (M=4.43). This difference trended towards significance in a linear mixed model [F(2, 26)=2.87, p=.075]. Although replication in a larger sample is warranted, the initial results provide preliminary support for individually tailoring activity pacing instruction on joint stiffness in OA.

## SESSION 1085 (SYMPOSIUM)

### MEASURING PERSON-CENTERED COMMUNICATION

Chair: *K.N. Williams, School of Nursing, University of Kansas, Kansas City, Kansas*
Co-Chair: *L.J. Medvene, Wichita State University, Wichita, Kansas*

The nursing home culture change movement is underway with goals of transforming long-term care to be more home like and less institutional as a residential care setting for older adults who require supportive care. Long-term care facilities are adopting person-centered care practices such as allowing resident choice in scheduling meals and care activities, allowing menu selections for meals, including plants and animals in the environment, and reconfiguring unit structures into neighborhoods. As operational definitions for person-centered care are refined, measuring the achievement of person-centered care remains a challenge for clinicians and researchers alike. Because communication is an integral part of person-centered care, it provides an important outcome measure. Caregivers need to be able to elicit information from residents and engage them in conversation about their preferences and personal histories. Caregivers need to communicate respect for residents to develop supportive relationships. This symposium will present an overview of how person-centered communication fits within a framework of person-centered care at the nursing home facility level. Four different approaches currently being utilized to measure person-centered communication between nursing home staff and residents will be presented and illustrated for participants. Each presenter will demonstrate the application of their measurement system to communication samples and will report on their use of the measures in analyzing data from current research studies. Strengths and weaknesses of each approach will be highlighted and challenges and direction for future research will be identified through audience discussion.

### COMMUNICATION CHALLENGES AND OPPORTUNITIES IN ESTABLISHING PERSON-DIRECTED ENVIRONMENTS IN LONG-TERM CARE

D. White, *Portland State University, Portland, Oregon*

This paper reports on person-directed care (PDC) measures developed with residents in Assisted Living and their family members. Like PDC measures developed previously with long-term care staff, these measures focus on 5 domains: Personhood, knowing the person, nurturing relationships, comfort care, and autonomy/choice. Multiple methods were used in the development of resident measures including interviews and observations. Survey data were used for family measures. Areas of congruence were noted between staff actions and resident and family reports (e.g., residents are treated with respect, staff are easy to talk to). However, areas of divergence were also apparent, often due to poor communication (e.g., family members did not know whether caregivers knew preferred routines or about important people in their lives; residents did not have access to favorite activities, facility routines were at odds with resident preferences). Implications for policies and training to improve communication in support of PDC practices are presented.

### MEASURING NURSE AIDES' PERSON-CENTEREDNESS USING BEHAVIORAL CODING AND GLOBAL RATING INSTRUMENTS

L.J. Medvene, C. Coleman, H. Lann-Wolcott, *Psychology, Wichita State University, 1845 Fairmount, Kansas*

There is increasing interest in promoting person-centered caregiving within gerontology. However, few observational instruments have been developed to measure person-centered caregiving behaviors. In this study, two innovative coding instruments – the Person-Centered Behavior Inventory (PCBI) and the Global Behavior Scale (GBS) - were used to test the hypothesis that caregivers' person-centeredness would be positively correlated with residents' satisfaction with care. The PCBI is a behavioral observational tool and the GBS is a global rating scale. Both tools were developed based on the literatures in person-centeredness. The hypothesis was tested by coding 50 videotaped interactions between nurse aides and residents in two nursing homes. Caregivers' person-centeredness during caregiving was measured by the PCBI and the GBS. Residents' and aides' satisfaction with caregiving relationships and their ratings of the relationship "mutuality" were assessed by self-report, using paper-and-pencil measures. Initial results demonstrate a correlation between aides' GBS scores and ratings of relationship satisfaction.

### MEASURING PERSON-CENTERED COMMUNICATION: TOPICS OF CONVERSATION

K.N. Williams, B. Harris, K. Ward, A. Weber, *School of Nursing, University of Kansas, Kansas City, Kansas*

Nursing home settings present a variety of barriers to person-centered communication. Heavy workloads focus staff on tasks, rather than interpersonal topics of importance to older adult residents. A system of qualitative content analysis, using coding developed in a prior study, was applied to measure interpersonal versus task-focused topics of communication in staff-resident morning care conversations (N=76) collected before and after a communication intervention. The intervention utilized digital photo frame displays as reminders to cue staff to the personhood of residents (N=6). Each staff utterance was coded for primary topic: superficial, interpersonal, focused on ADL, focused on technical aspects of care, or assessing the resident's condition. Comparison of baseline and post-intervention staff-resident interactions revealed a decrease in the proportion of staff task-focused communication with a 25% increase in the proportion of interpersonal content in specific staff-resident dyads. Changes in resident participation in communication with nursing staff will also be reported.

### PERSON-CENTERED COMMUNICATION AND MISSED OPPORTUNITIES IN THE NURSING HOME CONTEXT

M.Y. Savundranayagam, S. Kruschke, B.L. Overholt, D.M. Regalado, *Helen Bader School of Social Welfare, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin*

The personhood of residents with dementia is threatened in social contexts that highlight dependency, such as nursing homes. Kitwood, a proponent of person-centered care, developed four personhood indicators of effective communication with persons with dementia: recognition, negotiation, facilitation, and validation. These indicators were based on Dementia Care Mapping, an observational method which codes the quality of dementia care in terms of well- and ill-being. This study illustrates the application of the four indicators as measures of person-centered communication by nursing home staff. Conversations (N=23) between six staff-resident dyads were audio-recorded during routine care tasks over a 9-week period. Conversations were coded for (a) person-centered communication and for (b) missed opportunities where person-centered communication could have been facilitated. Examples of revised personhood affirming statements are illustrated. Findings revealed that missed opportunities tend to negate the positive impact of person-centered communication. Implications for staff training and self-monitoring of communication behaviors are discussed.

### USING AN ADAPTED ROTER INTERACTION ANALYSIS SYSTEM (RIAS) TO MEASURE NURSING AIDE-RESIDENT PERSON-CENTERED COMMUNICATION DURING MEALTIME AFTER AN INTERVENTION

L. Levy-Storms, G. Chung, T. Vandenberg, *Soc Wel, UCLA, Los Angeles, California*

The purpose of this paper is to present results from an intervention to improve certified nursing assistants' (CNAs) person-centered communication (i.e., non-task oriented talk) with nursing home residents. All CNAs in the study received a total of four hours of therapeutic communication training during one month. The core aspect of the intervention was a facilitator-led viewing of a DVD containing examples of real CNAs engaging in specific person-centered communication techniques. Before and after the intervention, 16 unique CNA-resident dyads were videotaped during mealtimes with nursing home residents. From the videos at both pre- and post-tests, coders used an adapted version of the RIAS to code the proportion of total utterances that were "affective" (non-task oriented) or "instrumental" (task-oriented). The results indicate that on average positive affective communication increased (38% at pre-test vs. 46% at post-test) following the intervention and instrumental communication decreased (60% at pre-test vs. 53% at post-test).

## SESSION 1090 (SYMPOSIUM)

### RESILIENCE AND TRAJECTORIES OF HEALTH AND FUNCTION

Chair: *E.S. Strotmeyer, Epidemiology, University of Pittsburgh, Graduate School of Public Health, Pittsburgh, Pennsylvania*
Co-Chair: *A.B. Newman, Epidemiology, University of Pittsburgh, Graduate School of Public Health, Pittsburgh, Pennsylvania*
Discussant: *T.M. Gill, Yale University, New Haven, Connecticut*

Resilience is defined as an adaptation to physiologic or psychological burden. Many older adults maintain physical and cognitive function in spite of health issues. However, the characteristics of resilient older adults have not been well examined. Longitudinal epidemiologic studies are uniquely poised to examine resilience and trajectories of health and function in aging populations. The Health, Aging and Body Composition (Health ABC) Study enrolled 3075 Medicare-eligible, well-functioning ambulatory adults aged 70-79 years old (52% women, 42% black) in Pittsburgh, PA & Memphis, TN in 1997-98, with contacts every 6 months and annual exams through 2000-01 and bi-annually thereafter. The Cardiovascular Health Study (CHS) enrolled 5888 Medicare-eligible, non-institutionalized ambulatory adults aged 65-100 years (58% women; 16% black) at 4 U.S. centers in 1989-90/1992-93 with contacts every 6 months and annual exams through 1999. The Study of Osteoporotic Fractures in Men (MrOS) enrolled 5,995 community-dwelling, ambulatory men aged 64-92 years in 2000-02 from 6 U.S. centers with a follow-up exam 4.6±0.3 years later. This symposium will describe the relationship of cognitive and physical performance declines to mortality (Dr. Watson) and the relationship of depression trajectories to mobility (Dr. Barry) in the Health ABC Study. Predictors of recovery from pain and exhaustion will be defined from the CHS (Dr. Thielke) and the role of vitamin D in frailty will be characterized for MrOS (Dr. Ensrud). The discussion will focus on factors/conditions associated with resilience and future directions for research in longitudinal epidemiologic studies.

### RATES OF DECLINE IN COGNITIVE AND PHYSICAL PERFORMANCE PREDICT MORTALITY IN OLDER ADULTS

N.L. Watson[1], C. Rosano[1], S.E. Hardy[2], R. Boudreau[1], E.M. Simonsick[3], S. Satterfield[4], H.N. Ayonayon[5], A.B. Newman[1,2], *1. Department of Epidemiology, University of Pittsburgh, Pittsburgh, Pennsylvania, 2. Department of Medicine, University of Pittsburgh, Pittsburgh, Pennsylvania, 3. Intramural Research Program, National Institute on Aging, Baltimore, Maryland, 4. University of Tennessee Health Science Center, Memphis, Tennessee, 5. University of California San Francisco, San Francisco, California*

Rates of cognitive and physical decline may be important prognostic factors among initially well-functioning older adults. Cognitive function (Modified Mini-Mental State Examination [3MS]) and gait speed (m/s) were assessed at baseline and after four years in the Health, Aging, and Body Composition study. Subsequent mortality was ascertained in 2,345 participants who had 3MS and gait speed data at baseline and followup (mean age ± SD 73.5 ± 2.8 yrs; 47% men; 38% black). 521 deaths occurred by the end of follow-up (median of 5.4 years). In a Cox proportional hazards model predicting mortality, greater rates of cognitive and physical decline were independently associated with higher risk: HR (95%CI) 1.18 (1.04, 1.35) per SD decrease in 3MS score; 1.59 (1.39, 1.81) per SD decrease in gait speed after adjustment for baseline performance and risk factors. Accelerated decline in cognitive and physical performance predicted mortality in this community-dwelling cohort.

### THE RELATIONSHIP BETWEEN DEPRESSIVE SYMPTOMS AND PERFORMANCE-BASED MOBILITY IN OLDER PERSONS

L.C. Barry[1], K. Yaffe[4], B. Penninx[3], H.N. Ayonayon[4], N. de Rekeneire[1], T.M. Gill[1], A.B. Newman[2], *1. Yale University School of Medicine, New Haven, Connecticut, 2. University of Pittsburgh, Pittsburgh, Pennsylvania, 3. VU University Medical Center, Amsterdam, Netherlands, 4. University of California, San Francisco, San Francisco, California*

Depression and mobility disability are dynamic conditions, yet little is known regarding the association between depressive symptoms and performance-based mobility function over time. Participants included the 2,324 members of the Health, Aging, and Body Composition study (52% female; 38% black; mean age 73.5±2.9 years) who underwent assessments of the 10-item Center for Epidemiologic Studies – Depression scale (CES-D), 400 meter walk, and 2 minute walk at years 1, 4, 6, 8, and 10 over the 10-year study period. Using generalized linear mixed models adjusted for demographics, chronic conditions, body mass index, and cognitive status, we found that as depressive symptom score increased, time to walk 400 meters increased ($\beta=0.42$; $\rho=0.02$) and number of meters walked in 2 minutes decreased ($\beta=-0.44$; $\rho<0.001$). Our findings help to elucidate the relationship between depression and mobility function and further highlight a mind-body connection. Additional research is needed to evaluate the reciprocal nature of these conditions.

### RECOVERY FROM PAIN AND EXHAUSTION IN OLDER ADULTS: THE CARDIOVASCULAR HEALTH STUDY

S.M. Thielke[1], H. Whitson[2], P. Diehr[1], A. O'Hare[1], P.H. Chaves[3], N. Zakai[4], A. Arnold[1], A.B. Newman[5], *1. University of Washington, Seattle, Washington, 2. Duke University, Durham, North Carolina, 3. Johns Hopkins University, Baltimore, Maryland, 4. University of Vermont, Burlington, Vermont, 5. University of Pittsburgh, Pittsburgh, Pennsylvania*

Little research has characterized how exhaustion and pain persist or remit over time. We analyzed the Cardiovascular Health Study to ascertain their course. Musculoskeletal pain was identified by a single Yes/No question. Exhaustion was defined using two items from the CES-D. We estimated the likelihood of recovery from these symptoms over six years. 40.3% of subjects reported pain and 21.0% exhaustion. 11.2% had complete remission of pain, and 16.5% of exhaustion. The symptoms remitted during at least one subsequent year in 56.2% of pain and 72.5% of exhaustion reporters. During all measured one-year intervals, 30.6% of pain and 48.6% of exhaustion reports remitted. Fewer depressive symptoms and lower BMI were consistently associated with recovery from musculoskeletal pain and exhaustion. Both symptoms are common in older adults but are not intractable. Both remitted at least temporarily in most subjects. This analysis clarifies prognosis and encourages efforts to modify these symptoms.

### CROSS-SECTIONAL AND LONGITUDINAL ASSOCIATIONS BETWEEN 25(OH)D LEVELS AND FRAILTY STATUS IN OLDER MEN

K. Ensrud[1], T. Blackwell[2], J.A. Cauley[3], S.R. Cummings[2], E. Barrett-Connor[4], T.L. Dam[5], P. Cawthon[2], *1. VA Medical Center / University of Minnesota, Minneapolis, Minnesota, 2. California Pacific Medical Center, San Francisco, California, 3. University of Pittsburgh, Pittsbhurgh, Pennsylvania, 4. University of California - San Diego, San Diego, California, 5. Columbia University, New York, New York*

Vitamin D deficiency and frailty are common with aging, but the association between these conditions is uncertain. To determine the cross-sectional and longitudinal associations of 25-hydroxyvitamin D (25(OH)D) levels with frailty status, we examined 1606 men ≥65 years with 25(OH)D levels and frailty status (robust, intermediate, frail) at baseline; 1354 men had frailty status (robust, intermediate, frail, deceased) reassessed 4.6 years later. After adjustment, men with 25(OH)D levels <20.0 ng/mL had a 1.5-fold higher odds of greater frailty status at baseline compared with men with 25(OH)D levels ≥30.0 ng/mL (referent), while frailty status was similar between men with 25(OH)D levels 20.0-29.9 ng/mL and those in referent group. There was no association between baseline 25(OH)D level and odds of greater frailty status at follow-up. Low 25(OH)D levels (<20 ng/mL) were independently associated with greater frailty status at baseline, but did not predict increased risk of greater frailty status at 4.6 years.

## SESSION 1095 (PAPER)

### A GLOBAL VIEW OF END OF LIFE RESEARCH

### PALLIATIVE CARE AROUND THE WORLD: AN EXAMINATION OF STANDARDS AND GUIDELINES

S.M. Mwangi, *Gerontology, Miami University, Oxford, Ohio*

Palliative and hospice care have gained acceptance in many corners of the world as a way of improving the quality of life for older patients and families facing life-limiting illnesses. During the past two decades, professional and national associations have embarked on the development of guidelines and standards for care. The bases on which these standards are created, and their level of development and acceptance vary from country to country. For instance, in the World Health Organization's definition of palliative care, four facets of physical, social, psychological and spiritual needs are emphasized. In countries such as U.S., additional aspects of palliative care are incorporated into standards. This study analyzed standards and guideline documents from 20 countries to better understand the evolution of palliative care around the world. Findings showed disparities and commonalities. Pain relief and emotional support to those suffering is advocated in all the countries, but attention to support the imminent process of dying for palliation patients and bereavement for the families is less consistent. The findings also show that the authority developing standards differs, with national and professional associations regulating the services in some countries, while groups of physicians serve that role in others. Finally, the importance of multidisciplinary teams varies across countries, with Australia, Germany, U.S., and U.K. placing significant emphasis on this approach. Disparities are mainly due level of development of healthcare systems, integration of palliative care into the mainstream healthcare systems and availability of multidisciplinary staff to cater for different aspects of palliative care.

### TERMINAL DECLINE AND SUBJECTIVE WELL-BEING CHANGES: EVIDENCE FROM THE SWISS CONTEXT

R. Valerie-Anne[1], M. Girardin[2], D. Spini[3], *1. FORS- Swiss Centre of Expertise in the Social Sciences, Lausanne, Switzerland, 2. CIG-Center for Interdisciplinary Gerontology, Geneva, Switzerland, 3. Labo Pavie, Lausanne, Switzerland*

We know that despite the increase of frailty with the aging process, subjective well-being remains quite stable in old and very old age. Several studies have already explained this subjective well-being stability through both personal resources (such as income, education, health) and processes of regulation (such as social and temporal comparison). Previous research demonstrates that social and temporal comparison are particularly efficient in maintaining the stability of both cognitive and affective well-being among octogenarians and nonagenarians. But despite the effectiveness of such personal resources and processes of regulation it has been shown that psychological change at the end of life reflects a combination of age, mortality and pathology related processes. The aim of this paper is to provide information about the well-being deterioration as a function of distance to death. To explore how impeding death contributes to changes in subjective well-being, we based our Multilevel Analysis on longitudinal data from both the Swiss Household Panel (SHP) and the Swiss Longitudinal Study on the Oldest Old (SWILSOO). Our first Multilevel Model demonstrates that even if both cognitive and affective well-being are affected by death proximity, it is the process of frailty which affects the level of subjective well-being. These first results suggest that late life changes are driven by mortality related mechanism like biological decline.

### TRANSITIONS IN THE LAST YEAR OF LIFE FOR CANADIANS IN ALBERTA

D. Mohankumar, D.M. Wilson, *University of Alberta, Edmonton, Alberta, Canada*

The issue of transitions in the location of end-of-life care has not been a major focus in hospice-palliative care research. Little information is therefore available on the numbers of admissions or readmissions to hospital, and the number of transfers between hospitals, ambulatory care settings, and home over the last year of life. The purpose of this study was to compare the use of hospitals in the last year of life for rural and urban Albertans. Secondary analyses were conducted on the two most recent years of provincial inpatient hospital and ambulatory care (ER, daysurgery, and outpatient clinic) data (April 2005 through March 2008). Each individual who had lived in the province for one complete year during this timeframe was retained in the analyses, with each having a full year of data reflected. Differences between rural and urban Albertans who died during that period (N = 19,398), on the number of hospitalizations, number of care transitions, highest users of hospitals, and age were examined. This study revealed that rural Albertans, as compared to urban Albertans had more care setting transitions (M = 4.23 vs. 3.37) and inpatient discharges (M = 2.05 vs. 1.70) during the last year of life. Data from the individuals who lived were also examined and will be discussed. These findings have implications for interventions targeted to these specific groups and suggest the importance of documenting end-of-life care preferences and home-based palliative care.

### BURDEN OF CAREGIVING AT THE END-OF-LIFE: AN EXPLORATORY STUDY AMONG THE SINGAPORE CHINESE

A. Chan[1,2], C. Malhotra[2], I.M. Woo[3], C. Goh[3], *1. Sociology, National University of Singapore, Singapore, Singapore, 2. Duke-National University of Singapore Graduate Medical School, Singapore, Singapore, 3. Lien Centre for Palliative Care, Duke-National University of Singapore Graduate Medical School, Singapore, Singapore*

End of life caregiving, in particular caregiving for terminally ill patients is a conventionally neglected perspective particularly in Asian settings. In this paper, we present data from Singapore to understand caregiver burden among caregivers caring for the terminally ill. Previous literature has shown that, in general, caregiving burden impacts not only the individual but families, employment and the existing healthcare system. Less is known about the impact of caregiving on the family members of terminally ill patients. In addition, most research on the burden of caregiving has been conducted outside Asia and to our knowledge there is currently no data (quantitative or qualitative) from Singapore assessing caregiver burden for terminally ill patients. Our study is an exploratory study to document the important elements for individuals caring for a person nearing end of life in Singapore. Patient-centred, caregiver-centred and contextual elements were found to contribute to well-being of end-of-life caregivers, with high importance given to 1) well-being of dying loved ones, 2) involvement of caregivers in patient-doctor communication and 3) closure with dying loved ones. These findings suggest that caregiver burden may be relieved by better patient-doctor communication with families in hospitals and the provision of more information on support services for caregivers.

## SESSION 1100 (PAPER)

### AGING ACROSS NEIGHBORHOODS AND COMMUNITIES

### THE SALIENCE OF NEIGHBORHOOD CONTEXT ACROSS THE AGES: SELF-RATED HEALTH OF YOUNG, MIDDLE-AGED, AND OLDER ADULTS IN NEW YORK CITY

E. Gaumer, *University of Chicago, Chicago, Illinois*

While there has been sustained attention to residential context as a potential source of risk or resilience for individual health and well-being, research has overwhelmingly focused on the consequences of concentrated poverty and the risks that such disadvantage represents for children and young adults. Recent work suggests that community context may be especially salient for older adults who experience higher levels of exposure to the residential environment due to life-cycle changes in daily round, health changes that impair physical mobility, and altered social networks. This paper uses data from a sample of more than 30,000 New York City householders to investigate whether neighborhood characteristics such as structural disadvantage and social cohesion are tied to the probability of reporting poor or fair health. By stratifying the analysis across three age groups: young adult (ages 18-29), middle-aged (40-64) and older adult (65-90), I investigate if, and how, these relationships differ across age strata. Findings show that among young adults, neighborhood poverty is not a significant predictor of poor health; however, for middle-aged and older adults, higher rates of poverty are associated with substantially higher risk. Social cohesion, on the other hand, matters to both young and older adults but in opposite ways: among younger adults, trust and helpfulness of neighbors reduces the risk of poor health but increases risk among seniors. These findings are net of individual-level characteristics and show that existing theories of neighborhood effects on health should be refined to identify the age-specific pathways through which neighborhoods convey risk or bolster resilience.

### THE EFFECT OF CLOSURE ON QUALITY: THE CASE OF RURAL NURSING HOME CLOSURES

J.R. Bowblis, *Economics, Miami University, Oxford, Ohio*

Due to structural changes in the market for nursing home care, nursing homes have experienced a decline in occupancy rates since the middle of the 1990s. The closing of a nursing facility when there is excess capacity can benefit the other non-closing facilities. However, facilities prefer if a competitor closes first, and may engaged in activities and business practices that allow the facility to not be the first in the local area to close. This war of attrition may lead to occupancy rates that are below the optimal level for efficient production of nursing home services. As a result, quality of care of all nursing home in the local area may be lower than facilities in areas with less excess capacity. This paper extends the literature on closures by studying the effects of rural nursing home closures on the quality of care provided by nursing homes that remain open and are in close proximity to the closed facility. A difference-in-difference estimator is used to determine how the treatment group, facilities within 15 miles of the closed facility, change quality between 1998 and 2004 compared to a control group of facilities that are within 15 to 45 miles of the closed facility. On average, facilities that are nearby the closed facility have higher quality after the closure. Furthermore, the occupancy rates of nearby facilities are 3.7 to 5.7 percentage points higher after the closure. These improvements occur because of efficiency gains in the remaining facilities from higher occupancy rates.

### KNOWLEDGE, PREFERENCES, AND ARRANGEMENT OF END-OF-LIFE CARE AND DECISION-MAKING AMONG JAPANESE AMERICAN OLDER ADULTS: COMMUNITY SURVEY FINDINGS

K.C. Nakao, *Mukogawa Women's University, Nishinomiya, Hyogo, Japan*

The purpose of the current exploratory and descriptive study was to understand the state of knowledge, preferences, and arrangement of end-of-life care and decision-making among Japanese American older adults. Using a self-administered mail-in survey questionnaire, the study collected data from 248 Japanese Americans age 50 and older residing in Southern California. The survey included questions on "Will/Living Trust," "Advance Health Care Directive," "Health Care Agent," "Life Prolonging Treatment," "Hospice Care," "Organ Donation," and "Funeral Planning." The participants showed a high level of awareness and knowledge about each type of end-of-life care. Although most respondents were favorable about making end-of-life plans in advance, particularly on the issues of "Will/Living Trust," "Advance Health Care Directive," and "Health Care Agent," to which the family-centered value played a crucial role, a remarkably fewer number of participants favored advance planning for "Life Prolonging Treatment" and "Organ Donation." The natural death and family-oriented thinking were shared values and strongly supported by the current participants. The respondents had a higher completion rate for end-of-life arrangements relative to that of the general public. To meet the needs of rapidly graying and diversifying older Americans including Japanese American elderly, the study recommends more community outreach and education to provide accurate information about end-of-life issues and more professional training for culturally-sensitive approaches at life's end. Study limitations and implications for public policy will be discussed, as well as implication for future research to identify within and between group differences of older adults from diverse backgrounds.

### THE RELATIONSHIP OF NURSING HOME RACIAL/ETHNIC COMPOSITION TO RESIDENTIAL SEGREGATION
